Decorative Arts and Furnishings

Decorative arts are those arts concerned with the design and decoration of objects, usually utilitarian, that in themselves do not necessarily possess aesthetic qualities. Certain of the decorative arts—basketry, pottery, and weaving, for example—are also collected under the term arts and crafts. By whatever name, they are distinguished from the fine arts in that the latter concern themselves with objects whose sole function is aesthetic appeal. The objects with which the decorative arts concern themselves range from humble household implements to monumental public works, and they include architectural units, furniture, rugs, and a host of items of metal, glass, clay, fabric, and other materials.

This article treats a number of traditional decorative arts in succession; the order in which they are discussed is suggested partly by historical development and partly by affinities. The opening section, an overview of interior design, sets a context in two senses: first, it begins with a general consideration of design that has implications for all the fine arts; and second, it discusses interior design as an art that makes extensive use of the products of the individual arts subsequently discussed in detail. Each section devoted to a particular form of decorative art includes discussions of materials and techniques and of significant historical developments.

The article is divided into the following sections:

INTERIOR DESIGN

Although man's desire to create a pleasant environment is as old as civilization itself, interior design, the conscious planning and design of man-made spaces, is a relatively new field.

Since at least the middle of the 20th century, the term interior decorator has been so loosely applied as to be nearly meaningless, with the result that other, more descriptive terms have come into use. The term interior design indicates a broader area of activity and at the same time suggests its status as a serious profession. In some European countries, where the profession is well established, it is known as interior architecture. Individuals who are concerned with the many elements that shape man-made environments have come to refer to the total field as environmental design.

The following section deals with principles of good design that are applicable to all design activities, with special emphasis on interior design, particularly as a creative and problem-solving activity.

Principles of interior design

Importance of total design

It is important to emphasize that interior design is a specialized branch of architecture or environmental design; it is equally important to keep in mind that no specialized branch in any field would be very meaningful if practiced out of context. The best buildings and the best interiors are those in which there is no obvious disparity between the many elements that make up the totality. Among these elements are the structural aspects of a building, the site planning, the landscaping, the furniture, and the architectural graphics (signs), as well as the interior details. Indeed, there are many examples of distinguished buildings and interiors that were created and coordinated by one guiding hand.

Because of the technological complexity of contemporary planning and building, it is no longer possible for a single architect or designer to be an expert in all the many aspects that make up a modern building. It is essential, however, that the many specialists who make up a team be able to communicate with each other and have sufficient basic knowledge to carry out their common goals. While the architect usually concerns himself with the overall design of buildings, the interior designer is concerned with the more intimately scaled aspects of design, the specific aesthetic, functional, and psychological questions involved, and the individual character of spaces.

Although interior design is still a developing profession without a clear definition of its limits, the field can be thought of in terms of two basic categories: residential and nonresidential. The latter is often called contract design because of the manner in which the designer receives his compensation (*i.e.*, a contractual fee arrangement), in contrast to the commission or percentage arrangement prevalent among residential interior decorators. Although the volume of business activity in the field of residential interiors continues to grow, there seems to be less need and less challenge for the professional designer, with the result that more and more of the qualified professionals are involved in nonresidential work.

The field of interior design already has a number of specialized areas. One of the newer areas is "space planning"—*i.e.*, the analysis of space needs, allocation of space, and the interrelation of functions within business firms. In addition to these preliminary considerations, such design firms are usually specialists in office design.

Specialized design firms

Many design firms have become specialized in such fields as the design of hotels, stores, industrial parks,or shopping centres. Others work primarily on large college or school projects, and still others may be specialists in the design of hospitals, clinics, and nursing homes. Design firms active in nonresidential work range from small groups of associates to organizations comprised of 50 to 100 employees. Most of the larger firms include architects, industrial designers, and graphic designers. In contrast, interior designers who undertake residential commissions are likely to work as individuals or possibly with two or three assistants. The size of the firms involved in nonresidential design is a clear indication of the relative complexity of the large commissions. In addition to being less complex, residential design is a different type of activity. The residential interior is usually a highly personal statement for both the owner and the designer, each of whom is involved with all aspects of the design; it is unlikely that a client who wished to engage the services of an interior designer for his home would be happy with an organized systems approach.

Most large architectural firms have established their own interior-design departments, and smaller firms have at least one specialist in the field. There are no precise boundaries to the profession of interior design nor, in fact, to any of the design professions. Furniture design, for example, is carried out by industrial designers and furniture designers as well as by architects and interior designers. As a rule, furniture designed for mass production is designed by industrial designers or furniture designers; the interior designer or architect usually designs those special pieces that are not readily available on the market or that must meet specific needs for a particular job. Those needs may be functional or aesthetic, and often a special chair or desk designed for a specific job will turn out to be so successful that the manufacturer will put such pieces into his regular line. The same basic situation holds generally true in the design of fabrics, lighting devices, floor covering, and all home-furnishing products. All design activities are basically similar, even though the training and education in the different design fields varies in emphasis. A talented and well-trained designer can easily move from one specialized area to another with little difficulty.

Distinction between art and design

In the discussion of the general aspects of design, it is important to note that there is an important distinction between art and design. A designer is basically concerned with the solution of problems (be they functional, aesthetic, or psychological) that are presented to him. The

artist is more concerned with emotive or expressive ideas and with the solution of problems he himself poses. A truly great or beautiful interior can indeed be called a work of art, but some would prefer to call such an interior a "great design."

AESTHETIC COMPONENTS OF DESIGN

A general definition of beauty and aesthetic excellence would be difficult, but fortunately there are a number of generally accepted principles that can be used to achieve an understanding of the aesthetic considerations in design. One must note, however, that such understanding requires exposure and learning; an appreciation of any form of art needs such a background.

A thorough appreciation of design must go beyond the first impression. The first impression of the interior of a Gothic cathedral might be that it is somewhat dark or gloomy, but, by the time the visitor senses its majestic proportions, notices its beautiful stained glass windows and the effect of light, and begins to understand the superb structural system that permitted builders of cathedrals to achieve their lofty goals, he can truly begin to appreciate the overall aesthetic qualities (Figure 1).

Importance of function

One of the key considerations in any design must be the question of whether a design "works" or functions for its purpose. If a theatre has poor sight lines, poor acoustics, and insufficient means of entry and egress, it obviously does not work for its purpose, no matter how beautifully it might be decorated. Such a design could be considered good only if it were thought of abstractly as a kind of walk-in sculpture. In some cases the building is meant to be sculpture rather than architecture. The Statue of Liberty, for instance, is primarily intended as a monument, despite the fact that it contains rather tortured interior spaces.

To use function as the only aesthetic criterion would be limiting, but it certainly is a valid consideration to be kept in mind. Designers are often tempted to overdesign or "style" an object or interior rather than design it. Some of the most beautiful objects of the 20th century are beautiful because they were the result of purely functional considerations. It is conceivable that future art historians will consider a modern jet plane the crowning artistic achievement of the middle of this century, rather than any building, interior, or conscious art form.

The aesthetic response to an interior and its furnishings must take into consideration the social and economic conditions as well as the materials and technology of the time. The elegant or ornate interiors that are usually associated with the 18th and 19th centuries were appropriate to the social and economic conditions of the nobility or the wealthy bourgeois who were the original occupants. The chairs were designed for formal living, and the elaborately carved furnishings were designed to be cared for by many servants (Figure 2, left). Such an interior is alien to the 20th-century way of life and would be totally inappropriate for a contemporary middle class family. It would also be inappropriate to use modern materials and processes to imitate earlier materials and processes (Figure 2, right). Many manufacturers try desperately to make plastic look like wood, stone, or just about anything but plastic. All

Synthetic materials and mass production methods are used to achieve furniture suited to its function.

aesthetic criteria have something to do with honesty. Some aesthetics have compared beauty to truth, and there can be little doubt that honestly expressed functions and honestly expressed materials and manufacturing processes are far more beautiful than fakery and imitation.

Relation of interior to basic structure

All interiors, by definition, occur inside buildings and therefore have a very real relation to these buildings. The best interiors today, as well as in the past, are those that relate well in character and appropriateness to the particular building. The furnishings designed and scaled for spacious country homes or palaces would obviously be out of place in a small urban apartment or suburban home. A strong and unusual piece of architecture such as New York City's Trans World Airlines terminal (at John F. Kennedy International Airport) could not be properly furnished with standard commercial furniture and products. The building, as well as the interiors, was conceived as a total design by the Finnish-born architect Eero Saarinen. Whether the observer agrees with the architect's concept or not, he clearly senses the strong interrelationship between the exterior and the interior—and therefore the aesthetic unity and success. Another successful interior and building is the Ford Foundation headquarters in New York City, the work of architects Kevin Roche and John Dinkeloo, with interiors by Warren Platner. The design is notable for its handsome spaces opening out toward an enclosed garden space (Figure 3). This obviously would not have been possible or appropriate if the view from the offices had been unattractive.

J. Zimmerman—FPG

Figure 3: Aesthetic unity in the interrelation of exterior and interior space: Ford Foundation headquarters, New York City, designed by Kevin Roche and John Dinkeloo, 1967.

The interiors within indifferent or unattractive buildings must strive to make up for the lack of design qualities in the structures. Thus, it is sometimes necessary to ignore the ugliness of the building and create an inward-looking beauty if no architectural character exists.

The most difficult aesthetic consideration is the problem of appropriateness. The appropriate atmosphere or character of an interior must take all the foregoing points into consideration. The architectural character of the TWA terminal would make it inappropriate for use as an office building. The appropriateness of individual, more intimate, and small-scaled interiors is more subtle. The interior design of a discotheque would hardly be appropriate for a research library, and a college classroom would hardly provide the desired atmosphere for a kindergarten. Many of these responses and relationships are complex and have psychological as well as aesthetic factors.

Elements of design. Of all the component elements that together form a completed interior, the single most important element is space. Spaces can be exhilarating or depressing, cheerful or serene, all depending upon the use the designer has made of the various elements that form the whole. Space is, in modern times, a costly commodity. The beautiful space of the Gothic cathedral achieved its success through generous proportions and lofty heights (see Figure 1). Due to the vast increase in construction costs in contemporary structures, spaces tend to be smaller and less generous; more skill on the part of the designer is required to give such limited spaces a particular atmosphere or character. On the other hand, sheer volume of space is not sufficient. There is hardly a larger space than the interior of the Vehicle Assembly Building at the John F. Kennedy Space Center in Florida, yet the aesthetic impact of that immense interior is negligible. A space need not be large and monumental to be aesthetically successful. The handling of mass and form even within a small structure can become exciting and beautiful. Frank Lloyd Wright was masterful in creating beautiful spatial sequences within residential-scale buildings (Figure 4). The Ford Foundation building is a relatively small structure among the huge buildings of New York City, yet the experience of that space is real and pleasurable.

Characteristics of space

Space can be thought of as the raw material which must be molded and shaped with the designers' tools of colour, texture, light, and scale. The interrelationship of design elements can be clarified by visualizing the result if the interior of St. Peter's in Rome were painted in garish colours or painted all black or sprayed with a foamy texture covering all surfaces or flooded with enormously intense floodlight that eliminated all play of dark and light. Obviously, any of these modifications would totally destroy the beauty and success of that space.

Colour is the quality of light reflected from an object to the human eye. When light falls upon an object, some of it is absorbed, and that which is not absorbed is reflected, and the apparent colour of an object depends upon the wavelength of the light that it reflects. The scientific attributes of colour and light in interior design are, however, less important than the skillful combination of colour values, hues, tones, shades, and above all textures. Although there can be no strict rules about colours and textures, it is well to remember the famous statement of the modern architect Mies van der Rohe that "less is more." His Crown Hall at Illinois Institute of Technology in Chicago, built in 1956, is elegant, understated, subtle, and is notable for its careful handling of textures and materials. To accept "less is more" as the sole guideline to design, however, would be a serious fallacy. Space, which is the essence of a meaningful interior, would be dull indeed if it were never varied—if there were no intimate spaces with low ceilings, in contrast to large spaces of greater height, and if spaces did not interrelate to provide the user with a sequential experience of moving from one to another. Monotony would also result if all interiors in a given building were of the same colour, material, and textural quality. Man needs variety and change.

The use of colour

The manipulation of space is a matter of both aesthetic and functional consideration. A small entrance vestibule in a building is needed to keep out wind and cold or heat and rain, yet it is equally important in providing a visual transition from outdoors to the interior of the building. The sheltered sleeping alcoves in early cave dwellings served not only to express man's desire for smaller and more intimate spaces for personal use but gave protection from draft or cold.

Much in our man-made structures is built of natural materials, and it must be remembered that these materials have natural colours and textures that usually are supe-

Value of natural properties

Hedrich-Blessing photo

rior to anything man can create artificially. Competent designers are very much aware of the innate qualities and textures of all materials, especially natural ones (see Figure 4). For instance, a sensitive designer would choose a simple oil finish on wood to bring out the beauty and quality of the grain rather than use the once-fashionable high-gloss finish that tended to obscure and change the texture. Textures are important not only for their appearance but also for their sense of touch, and for their effect on light absorption or reflection. Abrasive surfaces or very rough plaster would obviously be unpleasant to the touch and possibly dangerous in an interior, depending upon the use the interior is intended for. Textures can evoke feelings of elegance (such as silks) or informality (such as rough, tweedy materials).

Light, both natural and artificial, is one of the most important design elements, but unless surfaces are appropriate in colour and texture, the control and effect of light will be lost. The beautiful quality of space in a Gothic cathedral is very much related to the handling of light (see Figure 1). The source of daylight, high overhead or filtered through stained glass, creates exciting patterns of light and shade and a variety of intensities and pools of light. This same principle can be used in all interior spaces, and contemporary interiors often have skylights or high windows to provide variety and changing patterns of light. Artificial lighting is equally important, and, again, the same considerations of highlights, good overall illumination, and variety are important.

Concepts of design. The scale and proportion of any interior must always relate to the architecture within which the interior exists, but the other important factor in considering the scale of man's environment is the human body. Throughout the ages, designers and architects have attempted to establish ideal proportions. The most famous of all axioms about proportion was the golden section, established by the ancient Greeks. According to this axiom, a line should be divided into two unequal parts, of which the first is to the second as the second is to the whole. Leonardo da Vinci developed a figure for the ideal man based on man's navel as the centre of a circle enclosing man with outstretched arms. The French architect Le Corbusier developed a theory of proportion called Modulor, also based on a study of human proportions. Yet, at best, these rules are merely guidelines. They can never substitute for the eye and judgment of the designer, and it is reasonable to predict that attempts to make the all-powerful computer a substitute for the designer's sensitivity are also bound to be far from perfect.

The search for ideal proportions

It was stated earlier that the need for a changing scale and spatial relationship in the environment seems a natural one, almost a physiological as well as a psychological one. Perhaps the need for "personal" environment and scale can best be understood by considering some extreme examples. To a person flying at 30,000 feet in an airplane, the scale of anything seen on the ground appears so small that he loses touch with the reality of objects. People who fear heights are rarely bothered by the view out of an airplane because the distance to the objects on the ground has transcended normal perceptions of scale. In a similar manner, a person's reaction to the scale of a small house is quite different from his reaction to a large high-rise building. Details of pattern, texture, and material are accepted and expected in the small structure since they are in a meaningful scale with respect to man. By the same token, the sculptural ornaments on the tops of early skyscrapers seem absurd today.

Almost all principles of design for interiors can be comprehended with clear analytic understanding and common sense, without regard to dogmatic rules. If a beautiful 18th-century breakfront (which might be more than eight feet tall) is placed in an apartment with a ceiling height just an inch higher than the piece of furniture, it would obviously look out of scale. If a space is planned so that all the heavy and massive pieces of furniture are pushed toward one end of the room, with nothing on the other side, the room would obviously look out of balance. Yet balance and symmetry applied as inviolate design principles would result in very formal, very traditional, and somewhat dull interiors. Careful symmetry was a generally accepted rule during the Renaissance, and in any classic building one can be sure to find a carefully balanced and symmetrical facade, just as most formal and classic interiors have rigidly balanced plans. It is now recognized that balance can also be based on asymmetry. Both architecture and interior design in the 20th century have consciously broken with the many rules handed down from past eras. It is more important for a building or space to be expressive of its purpose. At one time, it was traditional for a theatre, opera house, or concert hall to embody certain forms and shapes without any real consideration of sight lines, seating distance from the stage, or acoustics. On the other hand, the Berlin Philharmonic Concert Hall (1964) works beautifully as a concert hall and expresses its purpose and function clearly in an exciting and dynamic way (Figure 5).

Departures from the rules in the 20th century

Balance and symmetry, colour, pattern, and repetition used to be a matter of adherence to a tradition. Until fairly recently, many interiors were painted in dark colours, often ignoring the fact that light reflection was adversely affected and that no real contrast or sparkling accent was achieved. In many contemporary rooms, however, most surfaces are kept in neutral or light colours, possibly with one wall accented in a strong colour or texture. An interior with uniform overhead lighting might be an efficient work space but would lack the character that can be achieved by providing some accent lights in small areas.

The designer's concern for honesty of materials and textures has brought about changing attitudes toward some of the conventional practices of interior decoration, such as the use of strongly patterned wallpapers and flowered prints. Any interior that has too many different patterns, too many textures, and too many repetitive features of any kind will appear overpowering, overly busy, overdesigned, and confusing. A designer often attempts to have a dominant theme or idea, be it colour, form, texture, or some rhythmic pattern. It must be noted also that design is influenced by changing attitudes and fashions. The movements in art and architecture of the 1950s and 1960s have influenced interior design in the direction of an emphasis on pure form, the absence of superfluous decoration, and expressiveness of materials. Recently, however, a kind of countermovement in the field of painting and sculpture has been influential. For instance, the use of large-scale graphic elements (supergraphics) in interiors has become popular and accepted, in spite of the fact that its very idea often consciously denies or destroys the visual clarity of existing architectural design features. Some of the leading designers in the United States and in several European

Figure 5: Dynamic, asymmetrical architecture creating an unconventional yet functional interior design space: Berlin Philharmonic Concert Hall, designed by Hans Scharoun, 1964

By courtesy of the Staatsbibliothek Preussischer Kulturbesitz Bildarchiv, Berlin

countries have also become very interested in large patterns, rhythmic geometries, and decorative surfaces, and this may point toward a new trend (Figure 6).

Sequential relationships

Most interiors consist of a series of interrelated spaces. It is important that the various spaces be designed in a sequential relationship to each other, not only in terms of planning but also in terms of the visual effect. A successful interior should be cohesive within each area and cohesive as a totality. It must above all relate to the building and to the architectural concept. A good example is the previously mentioned TWA terminal by Eero Saarinen. In spite of the extremely complex sculptural forms used, there is a sequence and clearly balanced rhythm that not only unifies the total composition but clearly relates it to the total architecture.

Jeremiah O. Bragstad

Figure 6: Supergraphic interior emphasizing decorative rather than architectural design: Hear-Hear Record Shop, San Francisco, designed by Daniel Solomon, graphics designed by Barbara Stauffacher, 1969

The best examples of design are those in which no visible difference exists between the interior and the exterior, between the building and its site, and between the many parts or spaces to each other and the total building. An example is the house of the American architect Philip Johnson in New Canaan, Connecticut. Johnson's home and its setting appear effortlessly united, with individual parts subordinated to the success of the whole (Figure 7).

Design relationships. The real and conscious relationship between art, architecture, and design is of long standing. Though mural painting was largely neglected in the mid-20th century, in the past great murals have been the planned focal points of interiors and have in a way determined the architecture (Figure 8). Similarly, sculpture or sculptural forms, as fixed and permanent spects of buildings, can be the most important design features if planned that way by the architect together with the interior designer and artist. Perhaps the best design is one in which there is no visible difference between architecture and interior and in which even the artwork is incorporated as an integral part of the total (see Figure 14).

The design relationship of interiors to architecture can be clarified by citing an extreme example: the stage set. A set for a theatrical production is a form of interior design but, unlike all other aspects of interior design, it attempts to create its own world and atmosphere concerned only with the play and not at all related to the world or even reality. The creation of a world of make-believe is precisely the function of a stage, but in real life it is impossible to divorce a particular interior from everything else around it. Sometimes a designer may attempt to create a "theatrical" interior, but the point being made strongly and unequivocally here is that every interior must relate to the architecture and to the nearby environment.

Art objects and interior design

Design relationships of individual works of art (paintings, prints, or sculptures) to interiors are most significant in terms of scale and placement, rather than in terms of subject matter, colour, or style. A very old painting, if it is good, will look well within a contemporary interior; a very modern piece of sculpture can be beautiful within an interior furnished with some beautiful traditional pieces. Any work of art, if successful within itself, is "correct" with any interior if properly placed or selected to work with the total space. Certainly there is no need to match

Figure 7: *Interrelation of interior and exterior space.*

Russ Kinne - Photo Researchers

colours of paintings to interiors or to select subject matter in works of art that reflect a particular theme, such as food for dining rooms or hunting scenes for the den.

Interiors as they relate to landscape or cityscape are sometimes misunderstood by architects. A crass but typical example is the ubiquitous picture window in suburban housing tracts. Often the only view from the window is the picture window of the neighbouring house. When the view is a beautiful one, it should be possible to plan the interior with the furniture plan and orientation such that seating arrangements can take advantage of the view and yet work for other functions, such as relation to a fireplace or a conversation group, as well.

SCALA — Art Resource

Figure 8: A simply designed interior space made vivid and compelling by frescoes on the ceiling and walls: Sistine Chapel, Rome, by Michelangelo, 1508–12, 1533–41.

Graphics in interior design

In many areas of interior design the field of graphics is taking on increasing importance. In every public or institutional building, signs, directories, and room identifications play an important visual part. Good architectural graphics have been stressed only in recent years, as a result of the increasing size and complexity of structures. Buildings such as airports depend upon clear and handsome graphics to make the spaces work and to make them aesthetically cohesive. A related aspect of graphics is the printed matter that is part of certain interior functions. Interior designers must be concerned with the design of menus, wine lists, napkins, and matchbooks in a well-designed restaurant. Designers dealing with stores or shops are concerned with the graphics of shopping bags, signs, and posters. Often the interior designer is the actual graphic designer, or he works together with the graphic designer, just as the architect works with the interior designer or landscape architect.

Modes of composition. It must be emphasized that there are many different moods, or modes of composition, that are possible in interior design. The recognition of this fact makes it difficult to apply valid critical criteria to these modes, since many of them are intensely personal. What may appear to be picturesque to one person might be ugly or cluttered to another. Each person brings to interior design his own cultural mores and his own prejudices, and in many ways he is psychologically conditioned and influenced to accept certain things and to reject others. In discussing various modes of composition, one must therefore take into consideration the occupants and their backgrounds, the locale and site, and then try to apply the most basic design principles as general guidelines.

Formal and informal compositions

Formal and informal compositions are relatively easily defined and classified; in fact, this distinction is useful throughout the history of furniture and interiors. Formal styles are usually associated with life at court or furnishings for the palatial homes of nobles or a moneyed elite. The informal periods usually are associated with rural living or the simpler pieces of furniture made by the local craftsmen in rural areas, where they plied their trade with limited tools, using local woods. Formal furniture, as a rule, leads to formal interior compositions. Balance and symmetry certainly tend to lead to formal compositions. Formality is not associated with any particular period. In fact, a very famous contemporary chair, the Barcelona chair by Mies van der Rohe (Figure 58), is an extremely formal and elegant piece. It would seem wrong to use that chair in a casual catercorner room arrangement.

Setting strongly influences the character of a space. By its very definition, a rustic setting would be rural and infor-

mal and would seem wrong and incongruous in a formal townhouse or city apartment. Since most business and public interiors are located in urban centres, any attempt to make such interiors look rustic or homey would be an aesthetic paradox. By the same token, it would appear equally incongruous to design a restaurant located in an old mill or barn in New England in a formal and urban character with elegant furnishings, whether they were contemporary or antiques of a formal nature.

Functional compositions

Certain modes of composition are determined by the function of the spaces as much as by the location and by the architecture. For example, a cozy or homey interior is normally associated with residential interiors or similarly intimate interiors, such as restaurants that may wish to appear "cozy." Some interiors, such as discotheques, require excitement and other interiors, such as funeral parlors, require serenity or dignity. One expects certain modes of composition for certain functions, but one's expectations are subject to many external influences, such as personal background, location, psychological associations, and changing fashions. For instance, the typical bank interior until about 1950 was expected to be solid, dignified, awe-inspiring, formal, and above all confidence inspiring. Contemporary design for business and industry has become accepted by all, and the early 1950s saw the logical extension of these firmly established design principles into the area of bank design. One of the first radical departures of traditional design for banking spaces was the Manufacturers Trust Company Manhattan office designed by Skidmore, Owings and Merrill in the early 1950s. It was the first widely published "glass" bank, and it set a trend that has become the new mode of composition for banks.

Fashion or design trends influence one's reactions to many kinds of designs. The term clutter is usually associated with Victorian design of the 19th century. Under the usual definition of the term clutter, one thinks of home interiors with collections of accessories and with an overabundance of knickknacks—the typical Victorian home (Figure 9). In the mid-1960s a new approach to office design, reflecting the "cluttered" approach, was developed. This office appears disorganized at first glance. Actually, the system (called office landscape; see below *Kinds of interiors: Public interiors: Space planning*) is very efficient and for that reason is deemed acceptable, even if the visual impact tends to be chaotic. Traditionally, office and business interiors were pristine, orderly, and very organized, and the idea of a cluttered appearance would have been anathema to designers.

Exotic compositions

The most difficult mode of composition for objective analysis is one that some people call exotic. The chances are that all exotic interiors are highly personal statements and cannot be rationally understood in theoretical design terms (Figure 9). To begin with, what may appear exotic to the average American could be very ordinary or even homey to another culture. Japanese or oriental design in general serves as an example. A Japanese style interior is extremely subtle, serene, and understated, yet to the uninitiated such an interior will appear exotic. Undoubtedly that same phenomenon holds true in reverse. Oriental people have often been impressed with Western-style design and have adopted it presumably because to them it appeared exotic. The increased mobility of the middle classes of many nations today has made foreign travel possible for more and more people, thereby tending to soften some of the very strong regional differences in design. The modes of composition are still discernible nationally or certainly by major geographic and ethnic divisions, but they tend to be less distinct. Many subtle differences exist within the same country, some of which are based on varying socioeconomic backgrounds, much in the manner of the traditional difference between formal styles (at court and in homes of nobility) and informal modes of composition for the country people and middle classes. The labels that one applies to these modes of composition are often only descriptive. They must not be confused with objective evaluation of design values. An interior that is by the creator's definition exotic or picturesque may or may not be a well-done exotic design.

Symbolism and style. There are many historic examples of symbolism in design, but often the symbolism is not a conscious statement so much as a more subtle reflection of style. Religious buildings, especially churches, have until recently been consistently traditional expressions of style or symbolism. The church and church architecture flourished during the Middle Ages, and the style of church architecture that became the dominant symbol was the Gothic style. Until the recent past, churches were still designed, as a matter of course, in Gothic style. It is interesting to note that a "Gothic" church designed and built

Symbolism in religious buildings

Figure 10: An interior shaped by objects symbolizing Theodore Roosevelt's personal interests and personality, North Room, Sagamore Hill, Oyster Bay, Long Island, 1880.

in 1820 can be clearly identified as such, and a "Gothic" church from the year 1920 has the imprint of that year as obviously as the date on its cornerstone. There has been a similar symbolic or stylistic tradition in the design of public or governmental buildings. Both interiors and exteriors of city halls, court buildings, and major government structures were usually in the "classical" style, symbolizing authority, power, and stability, based on our long historic association of these concepts with Greco-Roman antiquity and Renaissance thought.

Another form of symbolism in interior design has been the creation of interiors around specific themes or concepts. Among the earliest examples is the Egyptian tomb. The interior design and decoration depicted the life of the king or special events from his life, and the total interior was intended as a kind of magic to assure the occupant's journey into life after death and guarantee his happiness there. Another example of a symbolic interior created for a specific purpose is the Roman hunting lodge, Piazza Amerina, in Sicily, which has splendid murals and floors depicting animals and hunting. A more recent example of a similarly symbolic interior on the same subject is Theodore Roosevelt's home at Oyster Bay on Long Island, built in 1880. It is full of hunting trophies and mementos symbolizing his personal interests and his personality (Figure 10).

The styles that developed in interiors and in interior furnishings were always symbolic of the social structure of the society that created them. It is easy, for instance, to look at the graceful, feminine lines of a Louis XV chair, delicately curved and luxuriously upholstered, and to see it as a symbolic expression of the superficialities of court life. One can also look at some of the crudely fashioned early American furniture and see in one's mind the life of the settler who fashioned it. Life was harsh, time was precious, and articles of furniture were confined to essentials. The need for economical use of space was symbolized by dual-purpose, functional pieces such as dough boxes that served as tables and tables that turned into chairs and had storage compartments for the family Bible as well.

Symbolism in business offices

As functional and efficiency-oriented as business and office design is today, it is full of unwritten rules relating to symbolism. The design of an office reflects the status of the occupant. Top executives are located in the largest corner offices with the best views of the city and invariably are on the top floors of the corporate headquarters. The size of desks is a symbolic indication of the executive's importance in the hierarchy of the firm. The very top officers may, however, do away with desks altogether and have offices resembling living rooms—to symbolize the fact that they are beyond routine paperwork and above the need for standard office furnishings. The fashions (or styles) of design vary and develop even within a brief period of 10 or 20 years. Thus, another symbol—carpeting—has become somewhat outdated. Until recently, top executives expected wall-to-wall carpeting in their offices. Today such offices may have wood or other natural floors, perhaps with beautiful area rugs. The very idea of a private office is, of course, the most important symbol in a status-conscious business community (Figure 11). Designers have found, however, that the need for communication between executive and staff, including visual contact, often makes private offices less than efficient.

Symbolism in residential interior design occurs on many levels but again tends to be influenced by changing styles. When television first became available, the home screen became a symbol of prosperity and at the same time became the focal point of residential interiors. By the 1970s a television set had become a standard possession and was no longer a compositional emphasis; in fact, it was often concealed or casually incorporated into the total design.

A homeowner is likely to be very conscious of the image his house or apartment conveys. Traditional furniture, for instance, is still associated with elegance in the minds of many laymen, a situation that can lead to the acquisition of poor reproductions or meaningless imitations of nonexistent styles. To most people a real fire in a fireplace is a delightful physical and visual experience that often has nostalgic associations. Since they are no longer needed to heat houses, fireplaces in the 20th century increasingly have become a luxury and thereby a symbol of substance to many people. These circumstances have often resulted in imitation fireplaces of the worst possible design, with simulated fires.

Figure 11: Executive office resembling a residential interior: Fabergé Corporation Headquarters, New York City, designed by Dallek Inc., Design Group, 1968.

From the designer's point of view, design symbolism in public spaces is valid at times but can and should be used in contemporary terms rather than as stylistic imitation of past eras. An example of the success of such design can be seen in the new Boston City Hall, built in 1968, which symbolizes government, authority, and dignity in totally original and contemporary terms. There is little valid reason to consciously introduce symbolism into residential interiors, unless it is the kind of cultural symbolism exemplified in Japanese interiors, such as that of the Zen tea house (*cha-shitsu*), where certain design features reflect a way of life and have ceremonial meanings.

Contemporary symbolism

PHYSICAL COMPONENTS OF DESIGN

The foregoing section on aesthetic components stressed the fact that, in design, the whole or total effect is more important than the specific device or element used. The same is true of architectural components, and this should be kept in mind in the following discussion.

Ceilings. Although ceilings are in most interiors the largest unbroken surface, they are often ignored by amateur designers and even by professional designers. The result, especially in public and office interiors, is frequently a mass of unrelated lighting devices, air conditioning outlets, and the like. Ceilings were emphasized in the Baroque and 18th-century traditions: beautiful interiors of these periods had highly ornate, decorated ceilings, with painted surfaces or with intricate plaster details and traceries (Figure 12, left).

Few modern designers take advantage of the design possibilities offered by ceilings. One such possibility is the creation of textural effects with wood. Of course, one must respect the effect of a simple plaster ceiling in an otherwise well-designed interior; often the white plaster ceiling is needed to reflect light and to provide a calm cohesiveness to the space (Figure 12, right). Since most modern ceilings are low, a heavy texture or a strong colour could create a depressing feeling; hence, the popularity of a plain white ceiling. It is important for a plain ceiling to be just that: a surface without blemishes, without bumps, and without small unrelated areas of different height.

Value of the plain white ceiling

In contemporary public buildings there is frequently a "hung" ceiling below interior concrete structural slabs.

Figure 12: *Ceiling design.*
(Left) Highly ornate Rococo ceiling, Pilgrimage Church at Wies, Upper Bavaria (Germany), designed by Dominkus Zimmermann, 1745. (Right) Simple, white plaster ceiling, Christ Lutheran Church, Minneapolis, Minnesota, designed by Eliel and Eero Saarinen, 1950.
(Left) Toni Schneiders, (right) Balthazar Korab

The space between the slab and the "hung" ceiling is needed for mechanical equipment as well as to allow for the recessing of the lighting system.

An earlier section of this article discussed the variation of heights in relation to scale and space. It is important to keep such varying ceiling heights related to the plan of the room if such a device is to succeed. A lowered ceiling in a dining area, for instance, can be pleasant and intimate, but a lowered ceiling covering only part of the area can be most distracting.

Floors. Basically, there are two kinds of floors for interiors: those that are an integral part of the structure and those that are applied after the structure is completed. Interior designers working together with architects have the opportunity to specify flooring such as slate, terrazzo, stone, brick, concrete, or wood, but in most interiors the flooring is designed at a later stage and is often changed in the course of a building's life. Sometimes it is possible to introduce a heavy floor, such as terrazzo or stone, in a finished building or during remodeling, but these materials, beautiful as they are, tend to be too costly as surface applications.

Man-made, or synthetic, floor coverings are usually classified as resilient floors. The oldest of this type is linoleum. The resilient flooring materials marketed in the late 20th century include asphalt, vinyl asbestos, linoleum, cork, and vinyl. Cork, which is not a synthetic, is handsome, but is difficult to maintain and is not exceptionally durable. Basically, other resilient floor tiles are excellent flooring materials that are both economical and easily maintained. They can be given almost any appearance, which is a temptation that manufacturers are unable to resist. When the tiles are plain, in good colours or textures, they are very attractive and appropriate, but often they are made to imitate stone, brick, mosaic, or other materials, and the results are generally of a less satisfactory nature. Pure vinyls are the most expensive of the resilient floorings and have been the most tortured in terms of "design." The vinyls are the softest and most resilient of the tiles and are very easy to maintain. Asphalt tile is the least expensive and consequently the most widely used resilient flooring, although it is quite brittle and hard underfoot. Vinyl asbestos is somewhat softer underfoot and, being grease resistant, is easier to maintain than asphalt, but its cost is generally higher. Linoleum, which ranges in cost between the asphalt and pure vinyl floorings, is strong and suitable for heavy-duty uses.

Resilient flooring materials

Ceramic tiles and quarry (unglazed) tiles are made not only for such areas as bathrooms but, particularly in the case of quarry tiles, are suitable for almost any space. Installation usually requires a cement bed over the existing subfloor, making this material difficult to use in existing buildings. Like other natural materials, quarry-tile floors possess a natural beauty and have the additional advantage of easy maintenance.

Wood floors still account for a very large percentage of all floors, especially in residences. In addition to the strip oak floors, the standard for many apartment houses or homes, many beautiful prefabricated parquet patterns are available in a variety of woods and in many shapes and sizes. These wood tiles can be installed, just like the resilient floor tiles, over existing floors. Wood floors have great warmth and beauty but have the disadvantage of needing more care than do some of the synthetic tiles or quarry tiles.

Walls. Every wall is a material in itself; and ideally no material, if it is properly used, needs to be covered up. Some elegant buildings constructed since 1960 have used concrete in its natural texture—*i.e.,* showing the formwork left by wooden forms as a conscious expression of the material. During the 19th century, fakery in design was very popular, and part of the concern with the true expression of materials today is a revolt against the earlier tradition. In the 20th century, for instance, interior brick walls are considered very beautiful and desirable, yet many old townhouses have layers of plaster and paint or wallpaper on top of attractive brickwork.

It is not unusual for a decorative detail or device to survive long after the valid reason for it has disappeared. Wall panelling has been popular for hundreds of years, and, indeed, a natural wood texture adds warmth and elegance. The only way the craftsmen of earlier periods were able to apply wood panelling was in frames (stiles and rails) or wainscotting, since wood panelling was made of solid wood and had to be broken up into narrow dimensions in order to prevent warping and shrinking. Out of that need developed beautiful details of moldings, carved details, and carefully proportioned panelling. A similar art devel-

oped somewhat later in plaster. Obviously, 20th-century building costs and methods rarely permit real quality in elaborate panelling or highly ornate plasterwork (Figure 13), nor would this sort of imitative design be appropriate in a modern building. But wood panelling and plywoods in many beautiful veneers are readily available and provide a vast range of beautiful, if expensive, wall surfacing for important spaces. Prescored, pre-finished inexpensive plywoods, on the other hand, are often used as finishing materials for basement, recreation, or utility rooms in many homes in the United States.

Walls of wood veneer

The use of fake moldings, with printed moldings or panelling or with any of the countless imitation wall-surfacing materials from brick wallpaper to artistically poor wall murals, is the kind of decoration that a good designer avoids. Even so, not every interior should be a plain space with nothing but the natural walls. Highly decorative wallpapers have long been available in bold and exciting patterns. Often in 20th-century design a strong paper is employed on one wall only, instead of having the whole space surrounded by a dominant pattern. Many wallpapers, such as grasscloth and shiki silk papers from the Far East, have natural textures. For public spaces and for any space requiring easy maintenance and special cleanliness, a number of wallpapers have been developed that are completely washable and sanitary. Most of these are vinyl-coated fabrics, and some of them are extremely strong and durable and are particularly suited for such spaces as hospital or hotel corridors. Because these vinyl-coated wall fabrics are usually specified by designers and architects, the level of design is far superior to those made for the home.

There are many wall-surfacing materials using fabrics laminated to paper. These coverings provide warmth and texture, as well as acoustic properties. Fabrics in general have been used widely as wall-coverings in the past and continue to be popular.

A designer's imagination and the client's budget are the only limitation on the materials that may be used for wall surfacing. Some, such as ceramic or mosaic tiles, are extremely practical; some, such as cork, have excellent acoustical characteristics. For functional or for aesthetic reasons the designer may elect to use such materials as leather, metals, plastic laminates, or glass. No wall in itself should be designed or selected without relation to the total scheme.

Windows and doors. Windows and doors in contemporary design are not placed as decorative elements or as parts of symmetrical compositions but are primarily considered as functional elements and are expressed as such. If windows are carefully designed and placed for light, for ventilation, for air, and for view, decorative treatment is often unnecessary and a simple device such as a shade or shutter will suffice to control light and privacy. Most buildings, however, need window treatments, since no particular care in the placement of fenestration was taken by the builders.

Curtain characteristics

The most frequently used devices are curtains and draperies. Although semantically there is no clear distinction between the two, drapery implies more elaborate treatments with lining, overdrapes, valances, and tassels. A curtain, on the other hand, is lighter, more direct, less theatrical, and more functional. Frequently, a light material is chosen to provide privacy or light control with minimum emphasis. Curtains, however, offer only partial control over light, glare, and privacy; complete control or privacy often requires shades, blinds, or shutters. Window shades without overly ornate borders and tassels are a perfectly good device for those controls, and Venetian blinds are also a most acceptable treatment.

Since the 1960s designers have tried to simplify window treatments, and, if curtains, shades, or blinds were not deemed appropriate for functional or aesthetic reasons, devices such as chains or beads on windows or very simple sliding panels were found to be more effective than more elaborate treatments.

The essential considerations for windows must be based on the functional needs and on the overall aesthetic intent. If a space is well designed in architectural terms and presents a cohesive image, it rarely makes sense to feature a window or door. Poorly detailed windows in office buildings or apartment houses are often overcome or played down by using a simple curtain material covering a complete window wall. The wall-to-wall and floor-to-ceiling treatment of a window wall is frequently the only way to screen out unattractive details.

Planning for doors

Doors must be carefully planned, relating the swing and location to the functional needs, and their heights, colour, material, or textures to the adjoining wall surfaces or design elements in the space. Most doors used in the 20th century are "flush" doors—that is, they have unbroken surfaces made of wood or metal; even where glass is used the attempt is usually made to have maximum glass area unbroken by frames and moldings. Sometimes the entrance doors to important spaces are designed or decorated as compositional focal points, but usually the emphasis is on excellence in detailing and hardware rather than on decorative surface designs.

Figure 13: Ornate plasterwork to decorate wall and ceiling: dining room from Kirtlington Park, Oxfordshire, designed by Thomas Roberts, completed 1748. In the Metropolitan Museum of Art, New York City.

Other components. The detailing referred to in connection with the handling of doors is one of the most important factors in interior design. Every architectural component must be detailed well. Poor details make for poor design. The meaning of detailing in a design sense is more than the graphic explanation of certain components on a drawing. It means the way materials are put together, the way one part is fastened to another, the way parts and materials are expressed and articulated. Stairs or ramps are architectural components of great importance, whether in stores, in public buildings, or in homes. Since these structural features represent large vertical forms in space, they often become the dominant design feature in an interior space (Figure 14). Stairs in hotel lobbies, for example, are usually in very prominent locations. The actual stair design, however, is surprisingly restrictive and set. The height of riser and its relation to the tread is fixed, and variations for normal vertical circulation are extremely

limited. Matters of detail involve such considerations as whether the stair is open or enclosed, whether it is a bold sculptural form or an airy dynamic shape (resulting from the use of open treads without risers), whether the stair honestly expresses its material (be it wood, steel, or marble), or is wrapped in carpeting. The many detailing possibilities present a real challenge to designers and, unlike mass-produced windows, light switches, or plumbing fixtures, give designers a chance to design in a completely personal or creative way.

Maynard L. Parker

Figure 14: A ramp functioning as the focal element of an interior: the former V.C. Morris Shop, San Francisco, designed by Frank Lloyd Wright, 1948.

Placement of utility fixtures

Components such as heating units, electric outlets and switches, and telephone connections offer no design choice other than the limited selection among mass-produced products and the best placement within the space. The pattern created by the placement of fixtures is as important with walls or any other surfaces as it is for ceilings. A given wall may have doors, windows, electric outlets, switches, air-conditioning registers, and heating units (radiators or convectors). It is the designer's job to deal with all of these components by design, by organization, by placement or elimination, and by detailing. Often, the more bulky components, such as radiators, can be "eliminated" by building the unit into the wall or, in existing, poorly detailed buildings, by creating a "built-in" appearance through the inclusion of some design feature. Radiators or convectors are often housed in neatly detailed enclosures that may run the whole length of a window wall and may at the same time provide an additional surface under the windowsill. Depending on the location, a continuous enclosure may contain some shelving or storage elements, thus making use of the extra space not needed for the actual heating unit (or air-conditioning unit).

In large, nonresidential interiors, the mechanical components are often massive. For instance, the telephone installation needed in an office for several hundred people requires a very large space and a complex installation of conduits and other elements that affect the interior design. The air-conditioning or heating unit for a simple store may be fairly bulky, and again the designer deals with the allocation of space as well as with the mechanical function of the equipment. All of the mechanical equipment for buildings is specified or engineered by specialists, but it is essential that an interior designer have the basic knowledge and understanding to be able to coordinate the various specialties. The many pipes, stacks, and vents that go into a plumbing system, although not exposed and shown as a rule, are of real concern to the designer. Whether architectural components are expressed and detailed, whether they are concealed or built-in, they are incorporated in the design.

Furniture and accessories. To the layman, furniture is the most important aspect of interior design. It is a significant component of design to the professional as well, since it is the most personal and intimate product relating man to a building. It is also personal because it can be moved from one home to the next and handed on from generation to generation, and often furniture takes on important sentimental value. Accessories are even more personal, but they are less significant to the overall effect of the interior, since they are by nature smaller than furniture. Almost anything that people own or collect could be called an "accessory," including functional objects, such as ashtrays, and decorative objects, such as porcelain, glass, or ceramics.

Personal nature of furniture

Although some quite sophisticated furniture existed in ancient Egypt, the use of furniture was rare during the Middle Ages and only became significant in the West during the Renaissance. During most subsequent periods there have usually been close interrelations between architectural and furniture styles and modes of interior design. (That aspect of furniture will be discussed below under *Historical and stylistic developments of interior design.*) The 20th-century pioneers of design and architecture—such as Mies van der Rohe, Le Corbusier, and Marcel Breuer—were not able to find any suitable contemporary furniture available in the 1920s and 1930s when they built structures without historical references. They designed much of their own furniture, and some of these modern "classics" are still very much in demand. Well-designed modern furniture developed in Scandinavian countries in the 20th century out of the long tradition of craftsmanship and design prevalent in those countries. The real beginning of modern furniture design in the United States came only after World War II, and much of it was first developed for nonresidential uses. Charles Eames, George Nelson, and Florence Knoll are among the distinguished American designers who have pioneered furniture design and manufacturing processes. Their furniture primarily was introduced to the public through use in public or work spaces. A large segment of furniture manufacturers, however, has still not been touched by design of any kind, and furniture under such invented names as "Mediterranean" or "Italian Provincial" (both nonexistent historic styles) is still being foisted upon the public.

Use of built-in furniture

Whatever material or manufacturing process may be used, the important criteria that must be applied in furniture are function, comfort, and durability, together with aesthetic considerations. Architects and interior designers often prefer to build in furniture wherever possible, and, indeed, some of the best historic and contemporary interiors contain little movable furniture. An interior without any furniture or accessories would probably appear stark and uninviting, and it is clear that the personal touches possible through selection of appropriate furniture and accessories are very important.

One can use a vast array of decorative objects or plants as accessories. In a way, every accessory used in a home, office, or public space is in some way a part of the total composition, and must therefore be selected with care. No rules exist on what is "proper" other than the basic principles of design that were discussed earlier.

Lighting. Light is one of the key elements of interior design. Most interior spaces constructed in the 20th century are used as much with artificial light as with daylight; because of this lighting has become a very significant tool for the interior designer. There are three major aspects to lighting: function, aesthetics, and health. The latter factor is often ignored, but insufficient illumination can cause eyestrain and physical discomfort. Illuminating engineers have established recommended standards of illumination for various tasks and have also provided rules and standards relating to brightness of the source of lighting and controls for shielding the eye from direct glare. Light can be diffused and can, in general, be controlled very accurately.

Two basic types of lighting are used in modern interiors:

Figure 15: Fluorescent, incandescent, and neon light used to create a particular atmosphere or mood: Ocean Tank, New England Aquarium, Boston, architects and designers, Cambridge Seven Associates, Inc., 1967. The dim light of the aquarium is immediately evocative of the dark, mysterious underwater world.

By courtesy of the Cambridge Seven Associates, Inc.; photograph, Norman McGrath

Types of lighting

incandescent and fluorescent. The former is somewhat redder than daylight but contains all colours of the spectrum. Since fluorescent light has an uneven spectrum, colours tend to appear distorted. A mixture of the two is often the best way to achieve colour accuracy. Some of today's fluorescent lamps are close to daylight accuracy, and manufacturers continue to improve the quality of available lamps. Both types of light can be used in "direct" or "indirect" lighting in interiors or in a combination of these methods known as semidirect or semi-indirect (Figure 15).

Designers and architects strive to build in lighting as much as possible. Recessed lighting, lighting coves, and architectural lighting in general can be controlled much more efficiently than portable lamps.

A good lighting scheme must provide some variety in highlights, shadows, and accent lights to avoid monotony. An even, overall lighting system, such as a luminous ceiling, can be highly efficient, but it lacks character and interest. Most interiors require a certain flexibility for different functions within the space at different times of day and night. In certain interiors, such as stores and shops, lighting becomes a display and sales tool, and in festive spaces, such as ballrooms or theatres, the quality of light can provide sparkle and mood more effectively than any other component of design. One can think of the potential of lighting in terms of the theatre. Some productions are staged without formal sets, yet the changing mood and setting can be suggested by controlled illumination.

Design in portable lamps

Most intimate interiors depend to some extent on portable or fixed (ceiling and wall-mounted) lamps. The design of lamps, especially table lamps for homes, has somehow brought forth a vast array of bad designs, together with a smaller number of good ones. Many lampshades are similarly banal in design, but a shade as such is an excellent diffusor of light and shield against glare. Some lamps and shades are designed for specific tasks, others for accent lighting.

Fabrics. There are three basic aspects that determine appearance and suitability of fabrics for interior use: fibre content, weave, and pattern. Fibres are either natural or man-made. The important natural fibres are cotton, wool, linen, and silk. Although silk has long been considered the most elegant and desirable of all natural fibres, it does not stand up well under direct sunlight and heat and, in general, requires more care than most other fibres. Wool, like silk, is an animal fibre; depending upon its weave, it can be made into extremely strong and beautiful fabrics and is therefore very much in demand for contemporary interiors. Both cotton and linen are made from vegetable fibres and are both durable and pliable. Unless cotton and linen are interwoven with other fibres, however, they are not generally as strong as wools or man-made fibres and tend to be restricted to light-duty interior purposes.

Man-made (synthetic) fibres in the 20th century abound under a variety of trade names, and new synthetics are continuously being developed. Some of the major families of synthetic fibres are glass fibres, acetate, acrylic and modacrylic, nylon, olefin, polyester, rayon, and saran. The chemical composition and processes used in the manufacture of man-made fibres make possible a variety of specific qualities. Some offer strength and elasticity; some offer resistance to fire, stain, mildew, sun, or abrasion; and some offer resistance to moisture and organic agents, others to crushing and wrinkling.

Families of man-made fibres

Many fabrics are woven in a combination of two or more fibres in an attempt to improve the appearance or utility or both. Another factor in selecting or specifying fabrics is the touch of the fabric, or the "hand." Certain fabrics made from man-made fibres seem unpleasant to the touch compared to silk or wool fabrics.

Weaving is an ancient art, and fundamentally there is little difference between the very early handlooms and the power looms found in major textile plants today. The three most common weaves in use are plain weaves, which include basket weaves; floating weaves, which include twill and satin weaves; and pile weaves, which include both cut and uncut weaves. Weaving techniques of lesser importance to interior design include knitting, twisting, forming, and felting.

The pattern of textiles, especially in contemporary terms, is frequently the natural pattern created by the weave of the fabric, although patterns are also created by printing. In traditional textile terms, reference to pattern usually meant a historic style. The history of textiles ranges from early Egyptian and Oriental patterns to the present. Each era has developed fashionable and popular patterns. Contemporary textile designs, for instance, are usually abstract or geometric, but floral and large flowing patterns were also popular in the 20th century.

Colour is one of the most important aspects of fabrics in interior design, inasmuch as the colours of fabrics are frequently the most important areas of colour in interiors. Dye colours can be added to unspun fibres, spun yarns,

Colour in fabrics

or woven textiles. Colour fastness is a major concern to interior designers, for faded fabrics can be quite detrimental to an interior.

Natural elements. No man-made object can equal the beauty found in nature, and it is not surprising that the introduction of natural elements into interiors has always been considered desirable. In spite of their beauty, one cannot arbitrarily introduce a plant, a tree, or rocks, or water into an interior. The foremost considerations must be the location of the space, its climate, and its relationship to the outdoors.

Climatic considerations determine the kind of plant, flower, or tree that can prosper in an interior. The most beautiful plant will not survive long under adverse conditions, and a dying tree or plant certainly offers no decorative advantage.

The location and orientation of interior to exterior spaces is another important consideration in the introduction of natural elements. In warmer climates, it is possible to have a gradual transition between interior and exterior, and plants providing this natural transition will look well and will prosper. In colder climates a real barrier of glass or a solid wall separates the indoors from outdoors, and at best the transition can be made visually.

There are a number of simple devices that make it possible to keep delicate plants and flowers alive under controlled conditions. Greenhouses in all sizes, ranging from window size to room size can be the most delightful areas of an interior, but obviously special conditions and maintenance must be provided. The scale of plants or small trees must be considered. One large indoor tree can be a beautiful accent in even a small space. Too many trees or plants in a small space would be overpowering, unless indeed the space is designed primarily as a greenhouse space or plant room.

Natural elements other than plants and flowers that can be used in interiors are water, rocks, stones, or pebbles, and planting areas in natural soil. For large spaces, usually public buildings, pools or contained areas of water can be extremely beautiful and exciting. Some interior features have been created with running water and small recirculated waterfalls. Sometimes a small area of pebbles with a few plants or carefully chosen rocks can add a touch of real beauty to an interior. Even collections of rocks, minerals, seashells, and other natural elements provide the touch of nature that can make an interior come alive.

DESIGN PROCEDURE

Professional interior-design assignments may range from the design of a small apartment to extremely large and complex jobs such as the planning and design of all of the floors in an office building or the design of all the spaces in a hotel or resort. The procedures vary somewhat from one job to the next and depend upon the size of the design organization, but the following basic outline covers the usual procedures followed by professional designers.

Interview with the client

Preliminary phases. The first step is the interview with the client. This is often a series of conversations and must eventually lead to a mutual agreement. Clients usually have a good idea of their needs and preferences, yet an experienced designer frequently sees some needs not envisioned by the client, and often he must reeducate the client's attitude about preferences. Obviously, the interview must also convince the client that the designer is the right one for his needs. Most established professionals do not commence any design work nor engage in prolonged meetings and conversations without a retainer for their services. Depending upon the scope and complexity of the job, agreements between clients and interior designers range from simple letters written by the designers to lengthy legal documents, covering precisely the services to be rendered, as well as the procedures and responsibilities. The designer makes a survey, including an analysis of the client's present program, and he often prepares a new program. Frequently, for instance, a designer upon surveying existing facilities finds that the redesign of these facilities would be more suitable to the client's needs and more economical than the leasing of a new space or the adding of additional space. More often the situation is reversed: the client does not realize that investing in a major renovation of his space does not permit room for future change or expansion, and upon the design firm's advice new premises are obtained or built. Sometimes there is a question of whether a particular interior of some value or meaning should be restored or reconstructed, and again the experience of the interior designer is needed for those decisions.

When the job involves redesigning existing spaces, at a very early stage the interior designer will require very accurate plans of existing conditions. In many older buildings, there are no up-to-date plans, and the design firm must take exact field measurements in order to obtain plans and elevations for the existing spaces. These plans must also reveal whether walls are bearing (supporting) or whether they can be demolished. The electrical and mechanical system must be carefully evaluated, sometimes by engineers.

The need for up-to-date plans

For large jobs pre-architectural planning and programming can consume many months or even years. Major corporations contemplating major building projects need precise programs, analyses of existing facilities and equipment, and a number of alternate schemes and proposals. Based upon the functions performed by the various departments of a corporation and the interrelation of these departments to each other, designers actually prepare a schematic building shape (such as a high-rise building or a series of smaller structures), including a basic system for offices or other functions.

The final program outline is eventually presented to the client for approval prior to any actual design work. The budget obviously is a paramount consideration. Together with the program analysis, designers must frequently prepare an approximate budget or attempt to make their proposals based upon a budget set by the client.

Among the additional factors that must be considered are availability of materials and furnishings, maintenance of the interior, and the character or appropriateness of the planned scheme. Business interiors often represent large investments for the clients, and a delay of several weeks in the completion of a job, due to the non-availability of products or furnishings, could represent a sizable loss. In public interiors, such as hotels, stores, or educational institutions, the maintenance factors must be carefully analyzed. On a smaller scale, residential interiors must be considered with similar care. Maintenance factors for the floors of kitchens or children's rooms are important.

Maintenance factors

Design and presentation. After the completion of a program and the acceptance of the program by the clients, the actual design work can begin. Designers usually work on many alternative schemes. A single space such as a restaurant or a carefully designed store takes many days of preliminary design studies. As the size of the job increases, the interrelation of individual spaces increases the complexity of these studies, and it is quite likely that the designer will need a rough study model in order to visualize the spaces three dimensionally. Drawing and drafting at that stage is the designer's way of visualizing his own ideas and at the same time putting them in such a form that they can be communicated to his associates for discussion and eventually communicated to his clients. All the aesthetic components come into play at that stage of design, including colours, lighting, and textures, although at the early design stages no precise selection of materials or objects is made. Obviously, this creative phase of interior design is based on thorough research and critical analysis and is not simply the result of a sudden flash of inspiration.

Once the designer or the team of designers feels that a scheme has been arrived at within the stated objectives, a preliminary presentation will be prepared. Although a competent designer will try a number of possible schemes for every job, he will, as a rule, decide which of the many ideas he explored in rough form is the most successful and that will be prepared for a preliminary presentation. For important commissions, such a presentation might consist of a number of sheets or presentation boards showing plans, elevations, sketches, and renderings, and, in many cases, models as well. Most clients are not

The preliminary presentation

trained to visualize space from plans and elevations, and perspective sketches and renderings are necessary to fully explain a scheme. At the preliminary presentation the specific colours, furnishings, and details are not resolved yet, since the aim at that stage is to obtain the basic approval from the client.

Final drawings and specifications. If a preliminary presentation has been completely accepted, the designers can proceed to the final design stages. If changes have to be made, another meeting (or meetings) with changed presentations may be necessary.

Preparation of final drawings

The next stages of the design may consist of a series of drawings done by professional draftsmen or by the interior designer himself, if he works as an individual. Depending on the type of job, final drawings may consist of just a few sheets or a very large number of drawings. Plans, elevations, details, sections, and specifications are the language of architectural and design offices, and they are prepared with carefully drawn dimensions and notes for the many contractors who carry out the actual construction. Certain drawings may be done by subcontractors or related trades; for instance, the air-conditioning system is usually designed by air-conditioning engineers, and the duct work must be designed in connection with the lighting system in order to assure that lighting fixtures do not conflict with ducts. Similarly, mechanical equipment—such as heating or plumbing pipes, telephone cables, and electrical lines—must be coordinated to avoid conflicts and problems. Before outside firms or subcontractors become involved, the designer or design firm usually prepares the design drawings with sufficient information to enable various contractors to submit bids. Almost all major jobs are sent out for bid to several contractors, in order to provide the client or the designer as his agent with a series of competitive estimates.

On complex and costly design commissions a final and elaborate presentation may be prepared after the acceptance of the preliminary presentation. This might include very carefully drawn perspective renderings in colour. Many presentations include scale models and may consist of nothing but carefully crafted models.

Selection and specification of furnishings

Together with the preparation of final drawings, interior designers begin the process of final selection and specification of all furnishings. The process of selecting and ordering fabrics, furniture, lighting, and all other furnishings requires a thorough knowledge of available products. In large cities there are often hundreds of sources, but, in spite of the vast product choice available, it is not always possible to find just the right fabric or just the right piece of furniture. In such cases interior designers may have to design special furniture, floor coverings, lighting fixtures, or fabrics. Most interior designers are familiar with quality products and maintain within their offices samples and catalogs of furnishings that they consider of merit. The products that have been selected by the designer are usually submitted to the client either as part of the original design presentation or in a separate approval step. Methods of placing purchase orders vary. Many design firms and individual designers prefer to limit their activity to selection and specification and arrange to have the client's purchasing office place the orders. In other cases the designer places the purchase orders but then submits the invoices to the client for direct payment. In either case ordering and specifying is an exacting task. Delivery and availability is an important concern that the interior designer is responsible for. If a hotel is scheduled for opening at a specified date, it may be necessary to place orders for furniture and furnishings as early as two years before completion date in order to assure delivery on time.

Building supervision

Construction. The actual building of the interior, be it a renovation or a new construction, needs considerable supervision by the designer, although constant on-site supervision is not always required. For an office or residence, a few visits may be sufficient. The thoroughness of working drawings and details influences the degree of supervision that is needed: the more complete the drawings and specifications for a particular job, the less time must be spent on the site during the building stage.

In spite of the fact that the workers are usually highly skilled craftsmen, there are questions that can only be answered on the site, and there are always unforeseen problems that require changes or on-the-spot decisions. Many interior designers have considerable understanding of construction and building technology, can communicate with tradesmen intelligently, and are able to offer valuable advice and suggestions. The situation can also be reversed. Many construction workers are very skilled and knowledgeable and are able to offer suggestions that designers are happy to accept. The supervision must proceed through all stages of a job. Knowledgeable designers spare no effort to see that every phase of the job is done in the best possible way.

As with other furnishings, interior designers select, commission, or purchase artwork, plants, and accessories. In residential interior design, clients usually own many of these things or will certainly be involved in the selection and purchasing, but in interior design for commercial or public spaces this responsibility is in the hands of the designer.

From the foregoing discussion, it will be clear that the design of large interior jobs involves many detailed considerations from the inception to the completion. For this reason most large design firms dealing with hotels, governmental or institutional clients, or large business firms have developed work sheets and checklists for all aspects of the work. Each phase of a job is usually under the supervision of a job captain or chief designer, and each checklist or form is controlled and checked repeatedly in order to assure that everything has been considered and that the job is moving smoothly to completion.

Work-sheets and checklists

KINDS OF INTERIORS

Although the foregoing sections have mentioned different kinds of interiors, in reference to both aesthetic and physical components of design, there has been no specific discussion of different design considerations for varying interiors. The aesthetic criteria suggested in earlier sections are subject to considerable variation, depending on the kind of interior involved.

Residential interiors. Residential interiors are obviously much freer and much more personal for both the interior designer and the occupants than other types of interiors. In fact, homes that have been designed unconsciously by creative occupants without any standard decorative rules are often the most beautiful ones. Certain planning and functional considerations are constant in any residence, and, although these too may be ignored by the occupant who wishes to be strongly individualistic, they can provide at least basic guidelines.

Relation of one space to another

The planning of modern houses or apartments must take into consideration the location of certain needs in relation to others. The dining space should be near the food-preparation area, and the food-preparation area should be accessible to the entrance used to bring in food supplies and remove waste. Access to children's sleeping areas should not be through the adults' living spaces. Access to bathrooms should be close to the bedroom areas and should not be through living or dining spaces.

The furniture arrangement for a living space must take into account the occupant's life-style and preferences. If a space is planned for young people, no seating might be provided other than the floor, but, for the more conservative or older occupants, comfortable seating for conversation and other activities is essential. Open-plan houses (living, dining, eating facilities without separate rooms) work splendidly and beautifully for some people but might not be the ideal answer for a family with many children and a desire for privacy at the same time. The special storage needs that must be considered for many homes vary from bookshelves to storage areas for bicycles, from facilities for recorded music to storage of sporting equipment. Such facilities can often be added by interior designers, if not provided by the architect.

There are several types of residence, and each one may require a different approach, partially based on economic considerations. The private house owned by the occupant warrants not only built-in designs and other permanent design features (lighting, flooring, etc.) but, in general,

lends itself naturally to anything within the imagination of the designer and the budget of the owner. Cooperative apartments are prevalent in larger cities, and those that are bought outright by the owners can be designed and changed as long as the structure of the building is not tampered with. A different approach is usually called for in rented apartments or houses. Major changes and special furniture and other built-in features would be considered a poor investment by the client and would, as a rule, be frowned upon by the landlords.

Residences as status symbols

In the past, professional help for residences has been basically reserved for wealthy clients. The residences involved were often status symbols, and the furnishings were to a large extent traditional furnishings and antiques. The best of such ornately designed homes are authentic, museum-like interiors, which indeed only the very affluent can afford. (Most status-conscious interiors, however, consist of reproductions and imitations and have little to do with good design.)

Today, instead of being limited to the service of the wealthy, the designer has a widening and important opportunity in a totally different aspect of residential interiors: mass housing and low-income housing. Although only in recent years have some designers involved themselves in this area, with an increasing concern on the part of both government and private enterprise for the effect of environment, the field should offer a growing opportunity for challenging creative work. Such designers, as well as helping to create more liveable spaces for those with limited housing budgets, can also be of great help in assisting occupants to choose simple, sturdy, attractive, and functional furnishings. A major problem for many people, on a variety of income levels, is the high cost of furnishings; mistakes in judgment are too costly to be discarded and thus must be endured. The help of professionals can minimize this problem and also protect low-income families from being induced to buy installment-plan furnishings of poor quality and design.

Public interiors. *Space planning.* Although many designers are engaged in residential interior design, there has been a marked shift away from that field since 1950, and more designers than ever work in the design of public, institutional, and commercial spaces. Space planning for business firms, governmental agencies, and institutions is a significant aspect of office design and is concerned primarily with planning, allocation of spaces, and interrelations between offices, departments, and individuals. The aesthetic or design phase varies with the degree of importance attached to offices by the clients. In a large firm, the clerical, accounting, or filing areas tend to be well designed in terms of lighting, efficiency, space, and function but have few frills or design features. The executive offices, reception areas, and conference rooms, on the other hand, are frequently elaborately and luxuriously designed, since they serve as images for the corporations as well as status symbols for their occupants. Decisions relating to size of offices and their furnishings are basically arrived at through functional considerations. An executive frequently must seat groups of people in his office. A department manager or clerk will rarely need more than one or two extra chairs.

Pre-architectural planning has taken on such importance that many design firms provide this service. Through careful study and analysis, standards of typical offices, relationships of offices and departments to each other, the need for flexibility and storage, and many other aspects of work within a given business can be arrived at, and such a study then becomes the program for the actual design of a new building or premises. When truly large firms or governmental agencies are involved, space studies preceding the actual design may take several months or even years.

Office landscape

A rather recent innovation in office design is known as office landscape (from the German word *Bürolandschaft*). Above, in *Modes of composition,* it was noted that the appearance of a "landscaped" space might seem chaotic. Actually, however, the system was developed in the 1960s by a German team of planning and management consultants who made intelligent use of computer technology to arrive at predictable relationships between persons and departments in a given organizational structure. Office landscape also takes into consideration the high cost of building and the continuous need for change in large corporations. The solution offered by these planners was not to build the traditional permanent walls and private offices but to arrange a large open space in a purely functional plan. Divisions between people and departments are created by free-standing screens, and plants are often used to divide and enhance space. Office landscape has been used in several major installations in the United States, following considerable popularity in Europe, but there are skeptics who question the basic claims of office-landscape supporters that less space is required and that the resulting democratization creates a better spirit and working relationship among staff members.

It is interesting to note that even in conventional office planning there is controversy about whether or not the occupant of an office should be involved in its design. Designers tend to insist on making all decisions, and management usually supports that point of view, yet psychologists, among others, counsel that a greater involvement of the individual with his own personal environment would be desirable.

Governmental interiors. A notable characteristic of interior design for public buildings—such as court rooms, assembly halls (on all levels of government including the United Nations), city halls, and cultural buildings—is that the consumer is excluded from participation in decision making. Another is that in all cases the interiors try to present a very definite image or symbol. Governmental buildings, especially in the past, were designed to present a solemn, awe-inspiring, majestic, and even slightly ominous look, both in their architectural composition and their interior treatment of spaces. For centuries, marble, stone, lofty ceilings, and imposing architectural elements have been traditional.

The image of government buildings

Institutional interiors. Schools, hospitals, and universities are examples of institutions now extensively using the services of interior designers and architects. Many universities have staff designers dealing with the institution's many design needs, from office spaces to dormitories. Certain institutional needs, such as operating rooms in hospitals, are strictly functional, yet the patients' rooms and many other hospital facilities are very much within the scope of interior design. Until recently, however, such involvement was not prevalent, and it has been common to refer to a sterile, dull-looking space as "looking like a hospital." A greater recognition of the influence of the environment upon human behaviour has brought about increased emphasis on interior design for all kinds of institutional interiors. Indeed, even though up to now little work has been done by designers in penal institutions, it is a safe prediction that in a short time there will be considerable concern for the environmental qualities of these institutions, as well.

Commercial interiors. Contemporary designers are much involved with commercial spaces—such as stores, hotels, motels, and restaurants. Many designers and design firms specialize in highly specific spaces such as restaurants, and others may become specialists in the design of showrooms for the garment industry. Frequently, the design of a restaurant, shop, or hotel must be keyed to a theme. It might be a nautical theme for a yacht club or a theme based on the artifacts of the particular region in which a hotel is located. Obviously, all commercial spaces must be designed in a highly functional way. A store with a beautifully designed interior will fail if it does not work for circulation of customers, for display, for storage, and above all for sales. Some of these functional needs create difficult design problems. A hotel or motel room, for instance, must be designed for use by individuals, couples, and family groups. Maintenance is also an important factor in the design of commercial spaces.

Use of a theme

Religious interiors. Religious architecture is heavily influenced by symbolic concepts as well as by the ritual and traditions of a particular faith. Designers of religious interiors must, therefore, base their approach on a set of rules preceding all other design considerations. The simple and modest Quaker prayerhouses, for instance, express the

tenets of that faith as clearly as some of the richly appointed Roman Catholic and Eastern Orthodox churches.

Industrial interiors. Industrial interiors do not usually involve interior designers. There are, of course, many industrial spaces, such as workshops, laboratories, and factories, that have been planned by architects and designers, and there are a few that have stressed some aesthetic considerations. By and large, however, industrial interiors are created as strictly functional spaces. For this very reason, some of these spaces are quite beautiful. This may sound paradoxical, but, like the modern bridge or airplane, they can be extremely handsome without the conscious attempt to create beauty.

Special interiors. Although an attempt was made to classify the kinds of interiors that are the prevalent concern of interior design, there are many kinds of special interiors that at times fall within the larger field of environmental design and that do not fit into a particular category or even a professional subspecialty. Transportation design may be part engineering, part industrial design, part architecture, and part interior design. Interiors of ships are certainly interior design, but the interiors of automobiles, aircraft, and trains are often a combination of many specialties. The advent of large commercial aircraft has taken the aircraft interior out of the area of the strictly functional, and, indeed, the introduction of these large planes has seen an intense competition among the airlines to create spaces that go beyond the concept of mere seating. Also included in transportation design are the terminal buildings associated with air, road, and water transportation systems.

Transportation design

A less spectacular example is the field of exhibition design, another area of design having interfaces with other fields, including, in this case, graphics and advertising. Related to this field are museum design and exhibition and the preservation and restoration of historic buildings.

It is clear that any man-made interior or exterior space is influenced by design or its absence. More important than a listing of the various kinds of special interiors is the underlying fact that designers are becoming involved in all aspects of the environment. (A.A.F.)

Historical developments

The art of interior design encompasses all of the fixed and movable ornamental objects that form an integral part of the inside of any human habitation. It is essential to remember that much of what today is classified as art and exhibited in galleries and museums was originally used to furnish interiors. Paintings were usually ordered by size and frequently by subject from a painter who often practiced other forms of art, including furniture design and decoration. Sculptors in stone or bronze were often goldsmiths who did a variety of ornamental metalwork. The more important artists had studios with assistants and apprentices and often signed cooperative work. Many architects also designed interiors, including the accessories—furniture, pottery, porcelain, silver, rugs, and tapestries. Paintings often took the form of cabinet pictures, framed to be hung on a wall in a particular position, such as over a door. Murals were painted on a diversity of subjects; during the period of the Baroque style in the 17th century, murals sometimes were painted to look like an extension of the interior itself, making it appear more spacious. Mirrors were employed for the same purpose of adding space to an interior.

The deliberate use of antiques as decoration was unusual in most periods. Generally, in older houses elements of the previous decorative scheme were relegated to less important rooms when new decoration was undertaken to bring an old interior into line with current fashion. In this way many antiques have been preserved. The art market has existed from the earliest times for the purpose of providing both new and antique works for the decoration of interiors, but in early times the market in old work was usually limited to paintings by admired masters and goldsmith's work.

Museum collections of furnishings

Only within the recent historic past have any interiors but those belonging to the rich and powerful been considered worthy of consideration. Still more recent is the collection of the interior furnishings of the past by museums and galleries, where they are studied in scholarly isolation. The segregation of such objects in galleries, however, has led to an increasing misunderstanding of their original purpose; and the division of the arts by museum curators into the fine arts and the decorative (or industrial) arts has helped to obscure the original functions of interior furnishings.

To some extent the present attitude has resulted from the rise of the specialist collector since the 1840s. Porcelain and silver, for instance, no longer fulfill their original purpose as part of the household furnishings but are collected into cabinets, since they are so precious. Similarly, the small porcelain figures of Meissen, which were originally part of a table decoration and an integral part of a service, are now too highly valued to be so used.

ORIGINS OF INTERIOR DESIGN

The notion of interior design historically has arisen as part of a settled agricultural way of life. The tents of nomadic peoples were hardly suitable for the more permanent forms of decoration. Among Central Asian nomads, however, carpets and rugs have been employed to decorate and provide comfort in tents and portable dwellings, usually taking the form of coverings for floor and bed, and these have been the principal form of art of the peoples concerned. The oldest nomadic carpet, found in Central Mongolia, dates to the 5th century BC, but geometrically patterned stone reliefs from Assyria in the 7th century BC are thought to be based on earlier carpet patterns.

Hunting peoples living in caves decorated the walls with paintings as early as 20,000 years ago, but these were almost certainly votive paintings rather than decoration, and no trace of movable furniture has survived.

Primitive peoples. Although the practices of present-day primitive peoples sometimes shed light on the historical origins of those practices, there is too little art and decoration in such communities today to illuminate the beginnings of interior decoration. No clear-cut progressions of styles, like those that occurred in Europe, can be identified except among peoples who could hardly be regarded as primitive, such as the former civilizations of South America or the Benin culture of Africa. Nevertheless, even the poorest and most primitive peoples devote some time to the production of works that give them pleasure, and these works often are employed to decorate interiors. Primitive painting often consists of a series of abstract patterns, such as that on the pottery of the Pueblo Indians. Furniture, such as wooden stools, usually has some ornamental carving. Basketwork, wooden vessels, and pottery are decorated with abstract geometrical patterns, and an insistence on symmetry is the rule. Since most of these patterns—especially those to be found in basketry and textiles—bear no resemblance to natural forms, they probably arose from the nature of the techniques employed in making the objects in question.

Connotations of ornament

Ornament based on natural objects more or less realistically depicted probably had a magical connotation; animals, for instance, are intended to promote success in hunting. Even the most abstract and geometric of motifs have a symbolic meaning, which can be interpreted by those who know the key, and this meaning is almost always magical. There are few objects or motifs that do not have some meaning, and the making of objects that have no other purpose than the pleasure taken by their creator in executing them is very rare.

Origins in Western antiquity. Excavations in ancient Mesopotamia and Egypt suggest that the earliest equivalent of furniture consisted of platforms of bricks, which served as chairs, tables, and beds, no doubt spread with textiles or animal skins. There is also good reason to think that walls were painted and, in the case of more important buildings, decorated with mural paintings. Movable furniture first occurred only in the most important residences, such as palaces, and in public buildings. Furniture is of considerable antiquity, though it is known, for the most part, only from wall paintings, sculpture, and vase paintings. Some furniture survives from ancient Egyptian tombs from about 3000 BC in the form of beds, chairs, tables, and storage chests. It is in such furniture that dec-

oration is first seen—in the leg of the bull and the lion employed as a furniture support, especially for beds. It is from this point in the ancient past that the development of interior design can be traced historically.

INTERIOR DESIGN IN THE WEST

Ancient world. *Egypt.* In contrast with the monumental tombs and temples of stone, many of which remained intact to the 20th century, Egyptian houses were built of perishable materials, and, therefore, few remains have survived. Sun-dried or kiln-burnt mud bricks were used for the walls; floors consisted of beaten earth, and a thin coat of smooth mud plaster was often used as an internal wall finish.

In its simplest form the applied decoration was a plain white or coloured wash, but, in larger houses, patterns in varying degrees of elaboration were painted on the plaster. Rush matting was hung across most internal door openings and used as screening inside the small, high windows. It is probable that decorative wall hangings and floor coverings were made of rushes or palmetto woven into a pattern, since painted representations of such hangings have survived from 5th-dynasty tombs at Saqqārah. In the workmen's village of Kahun, built in the 12th dynasty (*c.* 1900 BC), some of the more well-to-do houses contained rooms decorated with brown-painted skirting, one foot (0.3 metre) high, then a four-foot (1.2-metre) dado (the lower portion of wall that is decorated differently from that above it) striped vertically in red, black, and white. Above this the walls were buff coloured with brightly painted decorative panels in the more important rooms, and ceilings were also often of painted wood. It may be assumed that the lavish tomb decoration of all periods was basically derived from the domestic interiors of their time.

Use of natural forms for decorative motifs

Many Egyptian decorative motifs are stylized from natural forms associated with the life-giving Nile. The lotus bud and flower, the papyrus, and the palm appear constantly with borders of checkered patterns or coiled, ropelike spirals, giving an air of space and elegance. The palace of the pharaoh Akhenaton and other large houses at Tell el-Amarna (*c.* 1365 BC) reflect a tendency toward naturalism in their ornamentations. Akhenaton, his queen Nefertiti, and their daughters are frequently represented, usually grouped affectionately together. Other painted panels show animals and birds with twining borders of vegetation. Molded, coloured, glazed ware was introduced to give a brilliant inlay of grapes, poppies, cornflowers, and daisies, all in natural colours. The use of square ceramic tiles as a wall surfacing was uncommon but not unknown. Primary colours were the most common, a brilliant yellow being among the most frequently used, but terra-cotta, gray, black, and white were all added to give contrast. Even floors were delicately painted to represent gardens or pools. One of these at Tell el-Amarna shows a rectangular tank with swimming fish and waterfowl, bordered with lotus and papyrus marshland, with an outer band showing more birds and young cattle in the meadows beyond. Furniture ranged from the simplest benches and ceramic pots to beautifully designed chairs, small tables, and beds in the homes of the rich, where many vases, urns, ceramic, wood, and metal utensils evince a fastidious, luxurious way of life.

Mesopotamia. Very little furniture survives from ancient Mesopotamia, principally because climatic conditions are not conducive to the preservation of wood. What is known has been learned principally from reliefs and cylinder seals. Furniture mounts of bronze and ivory have been excavated, however, and fragments of furniture were uncovered in the royal tombs at the city of Ur, in ancient Sumer. In quality of craftsmanship and decoration, Mesopotamian furniture was comparable to that of Egypt.

The mud-brick houses of the Sumerian and Old Babylonian periods in the Tigris-Euphrates valley resembled their modern counterparts in their rectangular outline and the groupings of rooms about a central court, which was either roofed or open. In most houses, decoration probably was confined to a wide black or dark-coloured skirting painted in diluted pitch with a band of some lighter colour above. Door frames were sometimes painted red, probably as a protection against evil influences, and where doors were used they may have been of palm wood. The poorer houses were simply whitewashed.

Assyrian relief panels and friezes of ceramic tiles

In the most elaborate Assyrian palaces the main decorative features were panels of alabaster and limestone carved in relief, the principal subjects being hunting, ceremonial, and war, as in the palace of the warrior king Sargon II at Khorsabad (705 BC). Panels and friezes of ceramic tiles in vivid colours decorated the walls inside and out, and it is evident that this brilliance of colour was a feature of much Assyrian and Babylonian decoration (Figure 16). Carved stone slabs were used as flooring, with typical Mesopotamian rosette and palmette (stylized palm leaf) borders. Occasionally, Egyptian lotus motifs also appear.

Figure 16: Brilliantly coloured glazed brick decoration, facade of the throne room, palace of Nebuchadrezzar II, Babylon, *c.* 600 BC.

Vigorous and warlike figures characterize both Assyrian and Babylonian work, and the standard of execution was extremely high. Naturalistic detail was often engraved on the surface of the figures and animals, which themselves were in relief. After the Persian conquest (539–331 BC) this vigour declined. The palaces built by the Persian kings Darius and Xerxes I at Persepolis show a lighter use of animal figures. Glazed and enamelled tiles were used on the walls, while timber roof beams and ceilings were painted in vivid colours.

Crete. The most important buildings of the pre-Hellenic Minoan and Mycenaean periods were the citadel complexes, housing the entire court of the ruler. The palace of King Minos at Knossos in Crete (*c.* 1700–1400 BC) gives evidence of a small but sophisticated society with a taste for luxury and entertainment and a corresponding skill in applied decoration. Frescoes (paintings executed with water soluble pigments on wet plaster) and some panels of painted relief decorated the walls of living rooms and ceremonial rooms, which were grouped asymmetrically round a series of courtyards (Figure 17). Many aspects of Cretan life were depicted, the recurring theme being the acrobatic

Cretan use of painted decoration

bullfighting on which a religious cult was probably centred. Even the backgrounds of friezes and panels, which depicted many-coloured painted birds, animals, and flowers, were given an effect of movement, being divided into light and dark areas. Plain dadoes and borders provided an effective foil and gave articulation to the interiors.

As seafarers, the Cretans could import a rich variety of materials for building and decorative purposes; a wealth of ideas can be seen in the fine pottery, carved ivories, and beaten gold, silver, and bronze with which their palaces were ornamented.

The pottery and metalwork of the Minoans was technically in advance of other Mediterranean peoples of the time, and they were especially expert in firing such large pottery objects as storage jars and baths. Some furniture, especially storage chests, was made of terra-cotta. A chalice made of obsidian, a volcanic glass about as hard as jade, could only have been shaped by grinding with an abrasive such as emery procured from Cape Emeri on the island of Náxos; the form was apparently based on metalwork. Excavations have proved the existence of an advanced sanitary system, with baths either of marble or terra-cotta.

Greece. A period of so-called dark ages in Greece followed the destruction of Knossos in *c.* 1400 BC, but Cretan civilization had already influenced the mainland before then. Small terra-cotta models of furniture and fragments of tables and chairs dating from as early as 1350 BC have been found. Homer's epic *Odyssey,* dating from the 9th–8th century BC, speaks of a chair inlaid with ivory and silver, and sheet copper was used to sheathe beams and architraves. The description of a bed reveals it to have been a rectangular wooden frame with coloured leather thonging, like the usual Egyptian bed, and inlaid with silver and ivory. At this time also, wooden vessels were decorated with sheet-gold ornament with repoussé work (ornament in relief made by hammering the reverse side).

Little or no Greek furniture survives from the classical period (5th century BC), but there is ample evidence that it was well constructed and elaborately decorated. The large number of surviving painted vases are a valuable source of information about many aspects of Greek life, and furniture of all kinds—chairs, tables, day couches used for dining, and a large number of accessories—can be identified. These paintings, in fact, were among the major influences on the French Empire style of the early years of the 19th century. Egyptian influence can be traced in some of the early pieces of furniture, an example being a type of chair having a single leg with a lion's head at the top and a single paw at the bottom. This also was to be a favourite theme of the Empire style.

Hellenistic mosaic floors

In the Hellenistic period (323–31 BC), domestic comfort and decoration were considered once more. Mosaic floors were an important decorative device, originally made of pebbles as at Olynthus but later developing into the black-and-white or coloured mosaics that were widely used throughout the Roman Empire (see the section *Mosaic* below). A central, finely designed panel with realistic motifs and a wide, more coarsely executed border of scroll or key patterns acted as a focus for the arrangement of furniture, which was still limited in quantity.

Rome. Much more is known about Roman interior decoration, and Roman furniture was based on earlier Greek models. From the beginning of the Christian era the predominant Western style was that derived from ancient Greece by way of Rome. Classical styles were based on mathematically expressed laws of proportion that were applied not only to buildings as a whole but also to much of the interior decoration.

Roman interior decoration is known both from literary sources, such as Pliny's *Natural History* and the *Histories* of Suetonius, and from excavations, such as those that uncovered the remains of the Golden House of Nero soon after 1500 and those at Pompeii and Herculaneum in Italy in the 18th century.

There are many misconceptions about the decoration of the period, most of which date from the 18th century and the classical revival that began soon after 1750. Many excavated bronze objects, including statues, and any bronze that remained above ground, such as the roofing of the Capitol, were melted during medieval times for new work, since bronze was a scarce and expensive metal. This led to the assumption that marble predominated, which is not necessarily true, especially in the case of statuary. Time and exposure to the weather has removed the colour from much of the marble that has survived, but in classical times it was commonly painted and sometimes gilded. Wall paintings at Pompeii and Herculaneum are ample testimony to this. Wall decoration began there about 150 BC, and, by about 80 BC, plastered walls were being made to look like masonry. Such decoration was combined with the true architectural features—*e.g.,* doors and pilasters (flattened columns attached to the wall). The panels are painted variously in yellow, black, magenta, and red, with some imitation marbling indicating an earlier custom of applying marble veneers. Rich colour was also supplied by superbly executed mosaic floors, elegant couches with coloured cushions, and bronze tripods and lamps, such as in the cubiculum of a villa at Boscoreale near Pompeii preserved in the Metropolitan Museum in New York City (Figure 18).

Roman wall painting depicted columns, niches, and open windows with elaborate imaginary views and figures beyond. Painted ruins, such as those in the Villa of Livia, Rome, were the precursors of the 18th- and 19th-century Romantic taste in western Europe.

It has been said that Augustus, who was emperor from

Figure 18: Frescoed room, from a villa at Boscoreale, near Pompeii, 1st century AD. In the Metropolitan Museum of Art, New York City.

Roman marbles and other decorative stone

27 BC to AD 14, found Rome of brick and left it of marble, and certainly the interior decoration of imperial Rome expressed the emergence of the city as a world power toward which flowed much of the wealth of the empire. Exotic marbles began to be imported, and brick walls were faced with polished slabs of white and coloured stone. In the more luxurious interiors or for special purposes, obsidian, a natural volcanic glass dark green or purplish-brown in colour, and copper-green malachite were occasionally to be found in the capital. A limited amount of window glass—mostly small, thick, and discoloured panes—was used, for sheet glass was difficult to manufacture. Large translucent crystals of selenite (a kind of gypsum) were sometimes employed to admit light.

Some of the large houses contained a picture gallery, known as the *pinacoteca,* for the display of easel pictures. These have now virtually disappeared, but mural paintings are fairly common. Pictorial decoration for floors and walls was supplied by mosaics, the picture built up of small fragments (tesserae) of coloured stones, mostly marble, or of small pieces of coloured glass backed by gold foil to increase its reflective power. The subjects are very diverse. Floor-mosaics in dining-rooms were sometimes decorated with simulated fragments of food, as though they had dropped from the table.

Roman furniture was made of stone, wood, or bronze. Villas were largely open to the air, and stone benches and tables were common. Wooden furniture has not survived, but bronze hardware for such furniture is well-known. Buffets with tiers of shelves were used to display silver. Tables were often made of exotic woods and veneers, with ivory, bronze, or silver trim. Tortoiseshell veneers were popular. The dining couches, which replaced chairs, were richly decorated, often with gilded silver or bronze. Chairs followed earlier Greek forms, and while no fixed upholstery was provided, cushions were plentiful.

Roman textiles

The art of tapestry came to Rome from Egypt, where the craft was an ancient one. Few Roman textiles have survived, and those have mostly been found in Egypt and were probably made there. Rugs woven on a linen foundation were imported from Egypt, and fabrics, including rugs, were imported from the Near East. The richest carpets came from Pergamos, in Asia Minor, and were the most highly valued. They were probably woven with gold and silver thread. Nothing survives of these rich textiles because they were all burned long ago to extract the metal. Roman walls were hung with tapestries, and pillars were decorated with textiles. Silk was imported from China until the time of Justinian, in the 6th century, when silkworms were clandestinely brought from East Asia and the industry was established in Europe.

The Romans were highly skilled glassworkers. Domestic glass was made in large quantities, both utilitarian and decorative, and factories were established for the purpose. Mirrors, however, were normally made of polished bronze or silver; if glass mirrors existed at all, they must have been very small.

The amount of bronze employed in household equipment of all kinds was vast. Small pieces of furniture, such as stools, were made wholly of bronze, and a few specimens have survived. Saucepans were made in factories, some bearing what appears to be the trademark of a swan. Lighting fixtures were also made in quantity, of prefabricated parts, and they played a large part in the decoration of the interior. By the 1st century AD enormous quantities of silver went into the making of such objects as large and heavy platters displayed on the buffets. Bowls and similar pieces of hollow ware were commonly decorated with repoussé ornament, less often with engraving, which is usually to be found on the backs of bronze hand mirrors. Antique silver commanded a high price.

Statuary in bronze, from Etruscan sources or looted from Greece and the Greek colonies, decorated the more important interiors. The theatre of Scaurus, for instance, housed 3,000 bronze statues. Some Roman statues have been excavated at Pompeii and elsewhere, but most were remelted. Only one Roman bronze statue has remained above ground in Italy since it was made—the equestrian Marcus Aurelius in Rome.

Pottery was not among the luxuries of ancient Rome. Vessels such as storage jars (amphorae), lamps, bricks, pipes, and architectural ornament were made in factories. Pottery for the table was usually of the so-called Samian ware, although it was made in many other places than Samos; this had a red polished surface and, often, molded relief decoration reminiscent of contemporary silver. Tableware, too, was made in factories and often marked with the name of the potter. Pottery vases of fine quality were made in imitation of those of Greece. They include most of the familiar Greek types, especially the krater (with a large round body, large mouth, and small handles), although the form often varies. The decoration is principally of the red-figure type (black with decorations in red) but is usually much more elaborate than on the Greek originals.

Classical themes and motifs

Themes of decoration are many, and most come from Greek sources. They became part of the vocabulary of classical ornament that was employed during later classical revivals, such as the Renaissance and the Neoclassical movement of the 18th century. The acanthus leaf is by far the most common, and it was in almost continuous use from the 5th century BC in Greece to the 19th century in the West. The Greek and Byzantine acanthus leaf is inclined to be stiff and formal; the Roman and Renaissance form is much more natural. The vine-leaf and grapes motif is also common, and the palmette occurs especially on painted vases. The ivy, laurel, olive, and honeysuckle (anthemion) are usually to be found as frieze ornament, sometimes in stylized form. Festoons, garlands, and swags of laurel were common decorative elements in relief sculpture. "Cable," or "twisted rope," a kind of plaited ornament, was often used for the same purpose. Rosettes—stylized simple roses with equally spaced petals—were widely used. Originally an Assyrian design, they have continued in use to the present. Egglike forms alternating with tongue- or dart-shaped ornaments originally were a carved stone architectural ornament; they were taken over in later times as part of interior plasterwork.

The lion was very popular, especially the mask and paws, and was employed over a long period, as late as the 19th century, as a furniture ornament or as a door-knocker or handle. Mythological animal forms included the griffin and the chimera, both of Mesopotamian origin, and the sphinx, from Egypt and Corinthian Greece. The head of the ram, a sacrificial animal, commonly ornamented altars and candelabra. The ox skull and horns occur during Roman times, but not often thereafter. The eagle, representing Jupiter, was the symbolic motif of the Roman legions. The human mask surrounded by foliage was common and is usually derived from the masks employed in the theatre or from the head of Medusa, which was especially used as a shield ornament. Atlantes and caryatids, male and female human figures, respectively, were originally used instead of plain columns on building exteriors but were later employed for a variety of ornamental purposes—for example, as part of the decoration of some Renaissance cabinets of architectural form. Trophies were always popular. Weapons arranged in a pattern were carried in the Roman triumphs and later sculptured on monuments. This classical form of ornament was later extended to other groups of implements: in the 18th century, for instance, rustic trophies were formed by grouping agricultural implements, such as spades, beehives, and rakes, into a decorative pattern, and musical trophies were made of musical instruments for the same purpose.

A common type of decoration surviving especially in Pompeii is the frieze of small putti, or cupids, in a variety of guises and at work at a large number of different tasks. These persisted in popularity until well into the 18th century, when porcelain figures of putti in disguise or in an allegorical pose became common. They were also painted on furniture or as part of wall decoration.

Grotesques

Equally popular, but remaining virtually unknown till the discovery of the Golden House of Nero *c.* 1500, are the ornamental motifs known as grotesques (because they were found below ground in a "grotto," a word that strictly means an excavated chamber containing murals). Roman grotesques were fantastic figures, human and animal, that terminated in leafage (usually the acanthus leaf) or in a

fishtail, in conjunction with floral and foliate ornament and arabesques. Revived by Raphael about 1517 for the decoration of the loggia of the Vatican, these motifs became widely popular, in many different forms, from the first decade of the 16th century until late in the 18th.

Middle Ages. From the fall of Rome, when the city was finally sacked by Odoacer in 476, to the 15th century, when the Renaissance was already well advanced, information about the decoration of interiors is scarce. Its history has to be pieced together from surviving objects and illuminated manuscripts.

Byzantium. The capital of the Eastern Roman Empire, Constantinople (formerly called Byzantium, later Stamboul, presently Istanbul) was a convenient meeting place for East and West. It felt the influence of Persian art and transmitted it to early medieval European Christian styles. Most surviving Byzantine interiors are ecclesiastical, although secular wall paintings and especially mosaics continued to be popular. The Iconoclasts of the 8th century, however, not only proscribed the making of images but destroyed most of those already existing. Ivory carving was highly developed, and furniture was inlaid with ivory plaques and decorated with carvings. Goldsmith's work, which had existed in large quantities in ancient Rome, was equally popular in Constantinople. Decoration was usually of the repoussé type, with subjects from classical mythology. Very few gold objects have survived, and most bronze work has also been lost. Decorative textiles of fine quality were common, and a few fragments have survived. It is in some of the rare fragments of patterned silks of the 7th or 8th century that the Persian influence is most often to be found. Silk at one time was imported in vast quantities from China.

Constantinople tended to become increasingly an Oriental city as the Greek influence introduced by Alexander the Great waned in the Near and Middle East and the new civilization of Islām was established. (Ge.S./Ed.)

Early medieval Europe. In the constant warfare that was waged in Europe in the early medieval period, material possessions dwindled to a minimum: a man did not own for long anything he could not defend and had little use or opportunity for interior decoration. If he possessed more than one house, his furniture and possessions would go with him from place to place. During this time, the arts came to be monopolized by the church, which grew to dominate all aspects of the medieval world.

By the 9th century the Romanesque style was well established in northern Europe. It made far greater use of the semicircular arch and vaulting than had the Imperial Roman style. Much of the sculpture decorating buildings was influenced by the Middle East. The court of Charlemagne in the 9th century was in communication with that of the caliph Hārūn ar-Rashīd, in Baghdad, and the Arabs had opened up a sea route between the Persian Gulf and China. Oriental textiles, imported through Venice and Genoa, began to be found in the more luxurious European interiors, and in the 13th century the first piece of Chinese porcelain, brought back by Marco Polo, found its way to the West and is still preserved in the treasury of St. Mark's, Venice.

Castle interiors

Late into the medieval period, the larger houses, generally called castles, were designed according to military rather than aesthetic principles. The main room was a spacious hall with timber or stone walls (sometimes plastered), an open-beamed roof, narrow slit windows (as yet unglazed), and a floor of stone slabs, tiles, or beaten earth. In the earlier houses the fire burned in the centre of the floor, and the smoke either drifted through a central hole in the roof or dispersed among the rafters; but wall fireplaces soon replaced this unsatisfactory system. Furniture was probably limited to plain stools, benches, and trestle tables, made of local timber, and some heavy chests in which personal possessions were stored. The feudal lord and his lady sat on more elaborate chairs on the dais (raised platform), and a coloured hanging of plain fabric sometimes decorated the wall behind them. Wall hangings and tapestries became more common in Norman times (1066–1189), when stone carving on doorways, fireplaces, window openings, column capitals, and arcading superimposed on the inside walls was also introduced. Such hangings can still be seen in the Norman castles of Rochester, Kent, and Chepstow in England. The whole community often lived and slept in the one hall, but as time went on, two main rooms—the hall and the chamber—were provided. At first, rooms were divided by woolen hangings, hung from iron rods or from the rafters. The houses of the poor were simple, timber-framed shelters with bare earth floors and undecorated walls. Such conditions, with variations according to local circumstances, were generally prevalent in western Europe until the end of the 12th century.

Late medieval Europe. During the 12th and 13th centuries those who had taken part in the Crusades learned something of luxurious living in the Near East, and as a more secure way of life was becoming possible at home, they began to improve their own living conditions. The castle slowly evolved into the manor house. Household equipment became more elaborate and important, no doubt partly because the women had played a greater part in household management since the absence of the men on the Crusades.

Curtains of finer texture began to replace wooden window shutters or heavy homespun hangings. Tapestries relieved the bareness of the walls and gave additional warmth to rooms, and other textiles and tapestries were draped over chairs and tables, and brightly coloured woven or embroidered cushions were used. The fine wood ceilings of the large rooms were sometimes coffered and often painted in bright colours, particularly in France. The disappearance of much of this colour with the passage of time lends a false austerity to surviving medieval interiors.

Development of specialized rooms

A greater number of rooms, serving special needs and giving increased privacy, came into use, although the house was still not planned as a whole. The kitchen, buttery, and pantry were placed at the lower end of the hall beyond a carved timber or stone screen, which, in larger houses, supported a minstrel's gallery. At the opposite end, there was a chamber, or withdrawing room, perhaps with a solar (upper room) above it, used as a bedroom or as a special apartment for the ladies. A guest room was occasionally provided. In the 13th and 14th centuries, the wardrobe was a room with presses for storing curtains, hangings, bed and table linen, as well as the clothing and materials needed by the members of the household.

Giraudon—Art Resource

Figure 19: Gothic courtly dining hall with tapestry covered walls, plaited rush mats, trestle table set with gold and silver tableware, and a side table for displaying household plate; Duc de Berry at table from the illuminated manuscript *Très Riches Heures du duc de Berry* by Pol de Limburg and his brothers, France, before 1416. In the Musee Condé, Chantilly, France.

Here sewing and tailoring were carried on, and the room became a combined workroom and storeroom, furnished with heavy, plain tables and chairs.

In the kitchen, rotating spits and adjustable hooks for suspending cooking pots were fixed into a vast hooded or recessed wall fireplace. Plain but pleasing utensils of wood, copper, and iron were kept on hooks on the walls, and enormously solid tables stood on the stone or tiled floor, which was strewn with sawdust or rushes (Figure 21). In the hall the rushes were mixed with fragrant herbs and helped to absorb some of the dirt, smells, and grease. By the 15th century plaited rush mats were common (Figure 19). The introduction of linen tablecloths resulted in a great improvement of manners and cleanliness at meals.

Ornaments and various luxuries, which had become more common during the time of the Crusades, proliferated in subsequent centuries as commerce with the Near East increased. Household plate, of gold or silver, was frequently displayed on dressers or cupboards as decoration and to impress visitors (Figure 19), and it was not unknown for these possessions to be roped off to prevent pilfering. Indoor arrangements for washing and bathing were considered a luxury. A flat-sided metal bowl was sometimes fixed to the wall of a living room with a swinging ewer or a small cistern with a tap over it and a towel on a hinged rod. Small convex mirrors were hung in the walls as early as the 15th century, such as the one in the background of Jan van Eyck's "The Marriage of Giovanni Arnolfini and Giovanna Cenami" (Figure 20).

The Gothic style

The Gothic style first made its appearance in the Ile de France, toward the end of the 12th century. It derived originally from Middle Eastern sources and was developed by Islāmic builders. It came to be widely employed in western Europe, where, for uncertain reasons, it gained the name Gothic by the 17th century. It is characterized by the extensive use of the pointed arch, by spacious interiors, and by walls pierced with numerous windows, often of stained glass (see Figure 1). The style had no fixed rules governing proportion, and decoration, generally, was the free expression of craftsmen within the limits of current fashion and the purpose of the building.

Knowledge of Gothic interiors derives from illuminated manuscripts (Figure 19) and panel paintings (Figures 20 and 21) from the few surviving *objets d'art*. Much use was made of textiles for covering walls, especially tapestries (Figure 19); the principal medieval centres of tapestry manufacture were Paris and Arras (see the section *Tapestry* below). European courts at this time were very mobile and moved from place to place: tapestries were remarkably versatile, for they could be taken down and rehung elsewhere. They were employed to partition rooms, and were sometimes suspended under a high roof to act as a ceiling. Rugs and carpets had been brought back from the East by the crusaders and were at first employed as a covering for a divan or, in the case of the finer varieties, as bed and table coverings. The carpet for the floor was introduced comparatively late (Figure 20). Weavers of Saracen origin had settled in Sicily and on the Italian mainland, and they produced all kinds of rich fabrics, such as silk and velvet.

Use of hangings

Furniture was not present in such quantities as in later centuries, chairs especially being fairly rare. Tables were long and rectangular, laid on trestles, with benches for seating (Figure 19). At the head of the table, for the principal person of the household, was a straight-backed chair. Chairs, generally, were the subject of a certain etiquette, being reserved for the most important people, and they were often surmounted by canopies. Retainers had to stand (Figure 19); less important members of the household were sometimes supplied with stools. Folding chairs, like the old Roman curule chair, appeared in the 14th century. Although a few chairs had seats and arms stuffed with rushes, it was more common to drape them with textiles and put cushions on the seats. Buffets, often superbly carved, were used as a stand for silver and for serving food.

Medieval bedsteads, with highly carved posts and canopies, were often of great size, and they were customarily occupied by several persons—as well as the favourite dogs, who slept on top (Figure 20). The Great Bed of Ware in the Victoria and Albert Museum, London, is reputed to have held six couples in comfort.

Goldsmiths' work was often decorated with enamel, and bronze was similarly treated. The usual technique was the champlevé type, in which the metal is engraved or carved and the spaces then are filled with powdered coloured glass, subsequently fused by firing. At Limoges and in the Rhineland a wide range of objects were executed: quite large works, such as tombs, as well as smaller pieces, such as *chasses* and reliquaries. Lighting appliances were made of bronze or wrought iron. Those for suspension were usually intended for oil lamps, and standing candlesticks and candelabra were provided with spikes onto which the candle was forced (pricket candle sticks).

Gothic decorative pottery

Very little decorative pottery was made, although the colourful dishes and vases of Moorish Spain are an exception. Tiles were extensively employed for both walls and floors in houses of the better class, and there was a proverb in Spain to the effect that a poor man lived in a house without tiles (see Figure 30). The technique of manufacture was often quite complex and included inlaying with clay of a different colour. The vogue for tiles was imported from Islām by way of Moorish Spain. Chinese porcelain was known in western Europe by the late 14th century but was, of course, extremely rare; indeed, specimens were often mounted in silver in the same way as the semiprecious hard stones such as amethysts, garnets, and peridots.

The Gothic style lingered in England and northern Europe much longer than it did in the south, and many more examples of it escaped destructive wars than on the Continent. The panelled room characteristic of the style and the period has survived more or less intact in England, where panelling with traces of paint can still be found.

Gothic ornament sometimes makes use of motifs similar to those of classical interiors, such as the acanthus leaf and the rosette, but the treatment is very different. The Gothic craftsman liked to abstract certain features of his model and emphasize them in a stylized manner, as in the heraldic eagle, especially as it is used on the reverse of dishes from Moorish Spain and in coats of arms like that of the Holy

Roman emperor. It no longer bears any resemblance to the naturally depicted Roman eagle but is stylized, with a geometrically drawn tail. Similarly, the lion has its open mouth, tongue, mane, tail, and claws treated in the same way. Compass work is a marked feature of much Gothic ornament. The cross, for instance, is never a plain cross but is ornamented with geometric motifs; it may represent a reemergence of some old Celtic motifs, which were often based on compass work. Much Gothic ornament is floral and foliate, freely and naturally treated in some cases but stylized in others. Like interiors, paintings were in bright colours. Some of the ornamental motifs to be found in objects intended for interior furnishing are architectural, like the crocket (projections in foliate form), the panelling of chair backs, and the doors of buffets (Figure 21).

Figure 21: 15th-century Flemish interior with Gothic ornamented furniture: "St. Barbara," oil on panel, attributed to Robert Campin, 1438. In the Prado, Madrid.

Islāmic countries. The Arab conquest in the 7th century AD and, in the 8th century, Muslim expansion into India and Spain had profound influence on the decorative arts throughout the known world, especially as most of the long-distance trading routes passed through Arab lands. The skills of the conquerors fused with the traditional skills of their subject peoples, and because Islām forbade the portrayal of human or animal form, whether for religious or artistic purposes, and encouraged the incorporation of Qurʾānic texts into design, religion played a considerable and direct part in the development of design. As with nearly every other society, the finest and most lasting buildings were of a religious nature, and, unfortunately, few domestic dwellings have survived.

Architectural quality and form were subordinated to intricate and richly coloured surface decoration. Perhaps the finest results were achieved in Persia, where a high level of technical ability already existed in combination with great lyrical sensitivity. There the principal decorative features were the ceramic tiles and tile mosaics that encrusted floors, walls, roofs, and domes both inside and out (Figure 22). The mosques of Isfahan, Meshed, and Tabriz, ranging in date from the 13th to the early 17th centuries, demonstrate a completely satisfactory use of colour in architecture. Lustred tiles with a combination of floral and geometric design date from the 10th and 11th centuries, and naturalistic flowers frequently give a gardenlike effect to the tile decoration. Iris, rose, carnation, tulip, pomegranate, pine, and date are depicted, always with delicately interlacing stems, and contained within plain or patterned borders. Blues of all shades, from turquoise to a deep ultramarine, are characteristic.

Islāmic tiles and mosaics

Patterns for tilework and patterns for the Persian carpets are frequently interchangeable. Carpet designers soon managed to circumvent the Muslim ban on the use of animal forms: lions, deer, leopards, ornamental birds, and, occasionally, even mounted huntsmen were depicted, the figures always judiciously placed to give the maximum decorative effect. Artistic achievement reached its peak under Shah Abbās I (AD 1588–1629), but well before this time Persian carpets, silks, and pottery were known and valued among Europeans, as they still are in the 20th century.

In Egypt and Sicily one of the results of Muslim domination was the introduction of a high degree of ornamentation on wall surfaces, once again principally by means of vividly coloured ceramic tiles. The patterns are more solid than those of Persia, filling up the areas between the containing arabesques and with less open backgrounds. Moorish design in Spain shows even more complex interlacing geometrical framework, which is filled in with formalized leaves, flowers, or calligraphic inscriptions. Ceilings and the upper parts of walls were modelled in flat relief with coloured and gilded arabesques, while the lower wall areas were tiled. The decoration was partly hand chiselled and partly molded. Such decorations may be seen in the Alhambra, built at Granada in the 15th century, a pleasure palace whose arcaded courts and halls are embellished with stuccoed decoration in honeycombed ceilings, stalactite vaults and capitals, tiers of horseshoe-shaped or stalactite-fringed arches, and pierced or latticed windows.

Decoration in the Alhambra

In the mosques of Turkey, walls were veneered with marble, and ceramic tiling was introduced only in small areas. Colours, too, are less exuberant in the large mosques, where a sense of space rather than of overwhelming decoration is preeminent. Domestic buildings were largely of wood, looking inward to secluded courtyards and gardens, but with elaborately latticed windows projecting at upper-floor level over the street. As in most other Islāmic countries, the wealthy furnished their houses with velvet and silk hangings, couches, and innumerable cushions (Figure 22).

Islāmic influence in India appears at its finest in the interiors of mosques, tombs, and palaces built during the Mughal period (1556–1707).

Renaissance to the end of the 18th century. The Renaissance was a revival of the old classical styles, and it is not surprising that it first showed itself to a marked degree in Italy. The Gothic style had made comparatively little headway in Italy, where it was regarded as barbarous except in some of the more northerly towns, such as Milan and Venice. The style had more or less coincided with a period of primitive commerce. With the Renaissance the complex commercial organization of ancient Rome began to be revived by the towns of Tuscany, especially Florence. Feudalism disappeared, and the bourgeois merchants and financiers of the town rose to power and influence. Money began to circulate, banks were established, checks and bills were honoured over long distances, factories were opened, and men grew rich enough to buy and commission works of art for interior furnishing from those who owned their own workshops, employed assistants, and were no longer reliant on a system of patronage. With the rise of the town and the invention of gunpowder, the fortified country house became obsolete.

Social influences of design

In and around Florence the new commercial civilization was most highly organized. The old Greek and Roman manuscripts had been preserved, not only by the Christian monasteries but to an even greater extent by the Muslims, and soon after 1350 these began to find their way into northern Italy. Men became increasingly dissatisfied

Figure 22: Manuscript illumination depicting the intricately patterned geometric and floral ceramic tilework characteristically used in 16th-century Persian interiors. "Bahrām Gūr in the Yellow Pavilion on Sunday," illustration from the *Khamseh* of Nezāmī, Tabriz School, 1524–25. In the Metropolitan Museum of Art, New York City.

with the spiritual outlook of medieval Christianity, and the old Greek curiosity and philosophical speculation began to revive.

The Renaissance was, in fact, a return to the mainstream of Western art after what could fairly be described as the Gothic interregnum. Nevertheless, a thousand years lay between the fall of the Roman Empire and the Renaissance, and the classical styles of the Renaissance bear the same kind of resemblance to those of Rome as modern Italian bears to Latin. They are similar, but by no means the same thing.

The Renaissance brought back the Roman vocabulary of ornament, although the emphasis was now sometimes in different places (Figure 23). The classical orders (columns with base, shaft, capital, and entablature) were borrowed, and adapted to dress the new architectural style. Architects became highly skilled in the treatment of space, and decoration often played a major part in defining and enriching their vigorous spatial effects. Classical architectural forms were used in plasterwork, inlaid woodwork, and painted decoration as well as for staircases, doors, windows, and fireplaces, which formed increasingly important and elaborate features of interior design. Decorative details inspired by the antique were also used, executed in a wide variety of techniques; garlands, caryatids (statues of women used as supporting pillars), lion masks, grotesques, reclining amorini (cupids), cornucopia (horns overflowing with flowers or fruit), arabesques (entwining scroll and plant motifs), and trophies of arms are among the most familiar. Floors of coloured and patterned marble paving are frequently integrated with the overall decorative scheme. Modelled stucco, sgraffiti arabesques (made by cutting lines through a layer of plaster or stucco to reveal an underlayer), and fine wall painting were used in brilliant combinations in the early part of the 16th century.

In Venice the transition from Gothic to Renaissance building came less abruptly, as demonstrated in the Doge's Palace, where a Gothic exterior is found in combination with a late 15th-century facade on the east of the courtyard and a series of High Renaissance council chambers, famous for wall paintings by the Venetian painters Paolo Veronese and Tintoretto. Wood panelling with flat pilasters and a molded frieze forms the lower part of the interior wall decoration, with the fine series of historical and allegorical paintings, above, divided into panels between painted and gilded moldings and pilasters. The ceilings of a later date are particularly richly painted, their heavily scrolled carved and gilt cornices and framing introducing a touch of the Baroque style. Windows with twin semicircular headed frames surmounted by a lunette (a semicircular wall area) and fitted into a third, larger round-arched opening are a typically Venetian feature of the waterside palaces. In these, as in all the great Italian houses of the time, the works not only of the finest painters of the period but of the sculptors, goldsmiths and silversmiths, wood-carvers, bronzeworkers and ironworkers were used to embellish the principal rooms. Silks, embroideries, and cut velvets were used as hangings and upholstery, together with elaborately cut and framed looking glasses and carved gilt pendant chandeliers, as in the Palazzo Corner-Spinelli, Venice (1480). Costly carpets were imported, and much fine linen was in use. Trompe l'oeil (realistic) effects of perspective were achieved in the painting of walls and ceilings and also with intarsia (inlaid wood) decorated panelling such as in the study of Federico da Montefeltro, formerly at Gubbio, Italy and now in the Metropolitan Museum, New York City (Figure 24) or in the Palazzo Ducale, Urbino (completed about 1500), where a startling effect is created simulating open cupboards full of books.

Venetian interiors

During the Renaissance, Venice became a glass-making centre and introduced many new techniques. Blue glass with fine enamel painting dates from the end of the 15th century. Excellent engraving was done with a diamond point as soon as glass of sufficiently good colour was produced, by using manganese to neutralize the colour introduced by impurities in the raw materials. Such glass, which was called *cristallo* from its fancied resemblance to the hardstone known as rock crystal, is the origin of modern crystal glass. The Venetians also imitated coloured hardstones in glass. Glass made white and opaque with tin oxide was sometimes used for enamel painting in the style of porcelain, and clear glass with opaque white threads embedded in it in lace-work patterns was called *vitro di trina.* The Venetians also made mirror glass of excellent quality; in the 17th century they supplied the mirrors for the Galerie des Glaces of the palace of Versailles. Large sheets, however, were not practicable until the French discovered a method of making plate glass late in the 17th century, when the national factory of Saint-Gobain was founded.

During medieval times, Italian wood-carvers had achieved a high level of skill in the decoration of churches; now they turned to secular furniture, for which they employed oak, walnut, cypress, and a new, rare, and expensive wood—ebony. (In 17th century France, the craftsmen skillful enough to be entrusted with this wood—who were also makers of cabinets—came to be called *ébénistes,* a term that remains the French equivalent of the English "cabinetmaker.") Many ancient Roman furniture-decorating techniques were revived. Inlaying with a variety of coloured woods, with ivory, mother-of-pearl, and tortoiseshell, with a mosaic of coloured stones known as *pietra dura,* and with painting and gilding in addition, ornamented the finest furniture. The chest (cassone), often commissioned on the occasion of a wedding, was decorated with elaborate painting and gilding, sometimes with a large pictorial subject and sometimes with elaborately carved work, which was later coloured. Italian furniture in its design often made use of architectural motifs. Cabinets were often exceptionally luxurious, with such elements as caryatids flanking central doors, arcades of semicircular arches, and triangular pediment tops. The interiors were sometimes small models of architectural interiors, with

mirrors inset to give an impression of spaciousness. Silver furniture, no longer extant, was used in considerable quantities in late Renaissance times, usually crafted from plates of silver beaten over wooden formers.

Majolica

An innovation in Italy, which rapidly spread throughout the rest of Europe, was tin enamelled pottery, known in Italy as majolica and farther north as faïence or delft. Colourful dishes were often painted in a style known as *istoriato* (history painting) with mythological and biblical subjects. As some of the subjects were taken from engravings of Raphael's work, this pottery became known during the 18th and 19th centuries as Raffaelle ware. The majolica potters, the best of them located in Tuscany, made extensive use of grotesques, which show the style at its best.

The old Roman fashion for small bronze figures was revived during the Renaissance, and the fashion for these in interior decoration continued almost to the end of the 19th century. The earliest were fairly exact copies of excavated classical bronzes and may have been forgeries intended for sale at the time as genuine Roman work. The art developed rapidly. Before the 16th century, bronzework was done by the goldsmiths, and, as in most goldsmiths' work, general effect was subordinated to meticulous detail. After 1500, when bronze became popular for lamps, candlesticks, sconces, inkstands, small freestanding decorative figures, and furniture mounts, treatment of suitable subjects developed along the lines laid down for full-sized sculpture. Many small bronzes were made, some of them in the grotesque style.

At the beginning of the 16th century, the revived classicism of the Renaissance began to be modified, and eventually the style divided into two distinct paths. One remained faithful to tradition. The architect Andrea Palladio took ancient Roman works as a model, basing his designs on the theory of proportion laid down by Vitruvius in the 1st century BC in the *Ten Books on Architecture.* The second path was initiated by Michelangelo and led by way of Mannerism to the Baroque style. In both these latter styles, a deliberate exaggeration of forms displaced the strict logic and precision of the High Renaissance and aimed to convey freedom of movement and to involve the spectator in the drama of the design. Mannerism had only a limited influence on interior furnishing, as in the bronzes by Cellini and by Giambologna. Poses are often strained, the torso twisted, and the musculature emphasized; the favourite Mannerist subjects are violent ones, such as the rape of the Sabines and Hercules slaying Antaeus.

Characteristics of the Baroque

Baroque was the style of the Counter-Reformation and was intended by the Jesuits to express the temporal power and riches of the Catholic Church in contrast to the austere doctrines of Protestantism. The theatricality of the Baroque style soon attracted the attention of princes, who wanted it to be used in the palaces they built (Figure 25). Coloured marbles were used extensively, frequently in combination with bronze and rich gilding. Coloured glass windows were often used for lighting special features. Walls were sometimes painted to appear to be a continuation of the interior, giving an impression of spaciousness. Certain materials were often simulated by others: *scagliola,* for example, is a mixture of marble chippings, gypsum, and glue that was widely employed to imitate brecciated marble. What appeared to be richly coloured marbles were often no more than painted wood. Drapery was frequently imitated in carved marble, and wooden columns, the purpose of which was purely decorative, were painted like marble or some other exotic stone. Marble or stucco was made to imitate brocaded hangings, as in the Sala Ducale, Vatican, where an effect of space from limited means is created. Basic techniques were unaltered, but all restraint in their use vanished in bold theatrical effects and sensual luxuriance of modelling. Walls became curved, pediments were broken (*i.e.,* with central part omitted), columns and pilasters twisted until the buildings seem to come alive with movement. Bernini exuberantly combined rockwork, figures, and draperies with columns, panelling, and vaulting.

From Italy these styles spread across Europe, where they were absorbed in varying degrees and tempered by the national or local taste and genius. Many Italian designers and craftsmen travelled and worked abroad in France, England, Austria, and Spain.

France. From the middle of the 15th century, ideas from Italy began to change the face of French buildings; this change came gradually, first in the applied decorative detail superimposed on basically Gothic designs, then extending to a symmetry and regularity of the whole. Indeed, one of the basic differences between the Renaissance in France and in Italy is that in the latter the revolution in style involved, from the very outset, the whole conception

of design. The centralization of power and the brilliance of French court life was consolidated under Francis I (1515–47) and had already resulted in patronage of artists and craftsmen from Italy. Since the need for churches had been fulfilled in the great age of Gothic building, the king and his court rivalled one another's magnificence in building new châteaux in the early Renaissance style. Stone and timber were readily available, with masons and carpenters skilled in their use.

Style of Francis I

Among the earliest attempts in the new manner are the additions made by Francis I to the Château de Blois. The spiral staircase, with its own open stonework tower, may have been designed by Leonardo da Vinci, who died nearby at Amboise in 1519. Even at this early stage, the decoration of the staircase ceiling with carved bosses (an ornamental ceiling projection) featuring the monogram and heraldic device of the king shows a typical French contribution to Renaissance decoration. Such shields and monograms formed an important element in many decorative features, being used in wall and ceiling panel design or on the large carved stone chimneypieces. The fine galleries of Francis I and Henry II (1547–59) in the royal Palais de Fontainebleau illustrate the increasing elaboration of applied decoration and colour (Figure 26). The flat ceilings are of wood, coffered, coloured, and gilded in a variety of geometrical forms outlined with fine moldings. Molded panels enclose paintings on the upper section of the walls, and molded or carved wood panelling the lower parts, as in Italy. Floors are of hardwood strips, sometimes repeating the pattern of the coffered ceiling above. Benches supported on consoles (ornamental brackets) are designed as part of the overall scheme of wall panelling. Italian artists had been employed at Fontainebleau and elsewhere, influencing the contemporary French architects toward a more Italian conception. Rosso Fiorentino and Francesco Primaticcio decorated the Galerie de François I, while the hexagonal coffered ceiling in the Galerie de Henri II was designed by the French architect Philibert de l'Orme. The architects Sebastiano Serlio and Giacomo da Vignola, together with the goldsmith Benevenuto Cellini, all worked for a time in France, and much of the decorative work in the châteaux of the Loire valley was executed by Italian craftsmen.

In the early 17th century and during the long reign of Louis XIV (1643–1715), formality and magnificence became paramount in the life of the court. Suites of large rooms elaborately decorated provided an opulent background for the King and his courtiers; such suites usually consisted of a vestibule, antechamber, dining room, salon, state bedroom, study, and gallery. Staircases were stately and spacious, offering a fitting approach to the main rooms. Decorative schemes incorporated the fittings, hangings, and furniture with that of the room.

Versailles

The Baroque style was admirably fitted to express ideas of luxury and pomp. It inspired the building of some of the finest palaces erected in Europe since the days of Imperial Rome. The palace of Versailles built in the mid-17th century and widely imitated, led to the French court style in interior decoration and furnishings. Versailles was intended to be the outward and visible expression of the glory of France, and of Louis XIV, then Europe's most powerful monarch. His finance minister, Colbert, set up a manufactory that made works of art of all kinds, from furniture to jewellery, for interior decoration. A large export trade took French styles to almost every corner of Europe, made France a centre for luxuries, and gave to Paris an influence that has lasted till the present day. The vast initial cost of Versailles has been more than recouped since its completion. Even Louis XIV's most violent enemies imitated the decoration of his palace at Versailles. In 1667 Charles Le Brun was appointed director of the Gobelins factory, which had been bought by the King, and Le Brun himself prepared designs for various objects, from the painted ceilings of the Galerie des Glaces (Hall of Mirrors) at Versailles to the metal hardware for a door lock. (It should be noted that at the Gobelins, as elsewhere in France, furniture was designed by artists or architects who had no practical experience of manufacture, whereas, in the great age of furniture making in England, most designs were made and executed by the cabinetmaker himself, who had an intimate knowledge of his material.)

Though the Baroque trend is well established in the Versailles interiors, generally speaking it was regulated in France by an underlying restraint that seldom permitted decoration or movement to dominate entirely. Besides the Galerie des Glaces at Versailles (Figure 27), the Galerie d'Apollon at the Louvre is an example of magnificence in decoration. The vastness of these rooms and the lavish use of marble, plasterwork, and painted ceilings (with the addition at Versailles of mirror glass panels) created an effect of overwhelming grandeur.

Transition from Baroque to Rococo

Among the architects and artists working at this time were Jean Berain, André-Charles Boulle, Jean le Paultre, Robert de Cotte, and Jules Hardouin-Mansart. Their work continued in the later period in which Baroque ornament was transformed into the airy, delicate Rococo of the mid-18th century (Figure 28). The beginning of this more fluent treatment can be seen in the work of Robert de Cotte at Versailles and the Hôtel de Toulouse, Paris. An immense variety of materials was used for the inlaid and decorated furniture; in a piece by Boulle, for instance, the designer employed—in addition to the tortoise-shell and brass inlay—ebony, copper, lapis lazuli, green-stained ivory or horn, and mother-of-pearl.

Despite its freedom from onerous restrictions, the Baroque style had preserved the classical idea of symmetry. Not until the early decades of the 18th century were there marked departures from the notion that an object divided vertically should consist of two halves that are mirror images of each other. The Louis XIV style embodied a passion for symmetry, but with the Regency of the duc d'Orléans, which began in 1715, asymmetry became one of the features of contemporary decoration and one of the major aspects of the Rococo style. The principal designer in this style, who was largely responsible for its development, was Juste-Aurèle Meissonnier, a goldsmith and *ornemeniste*. It is no accident that many objects in Rococo style, including furniture, look as though they had been designed by a metalworker. It has been said that Rococo began when the scrolls stopped being symmetrical. The influences that brought about this revolutionary concept are worthy of consideration.

The influence of oriental porcelain

Beginning in the early decades of the 17th century, Chinese porcelain and lacquer were imported into Europe in ever-increasing quantities. Porcelain, especially, attracted many distinguished collectors, including most of the royalty of Europe. This increasing use of Chinese art objects in European decorative art provided a powerful influence with no trace of classical tradition. Soon after 1650 the Dutch began to import porcelain from Japan, at first decorated in blue, but toward the end of the century in polychrome, painted either by, or in the manner of,

Sakaida Kakiemon. This was widely sought, and even more highly valued than Chinese porcelain. When Augustus the Strong, elector of Saxony and king of Poland, bought a palace early in the 18th century to house his collection, for instance, he called it the Japanische Palais, and in France Louis-Henri de Bourbon-Condé, duc de Bourbon, established a factory at Chantilly to imitate Japanese porcelain. The decorations of Kakiemon were markedly asymmetrical, as were the painted lacquer panels that were imported to be made into screens and furniture, and there seems no doubt that this feature also influenced European Rococo art.

Despite the quantities in which it was imported, the demand for Oriental porcelain could not be satisfied, and European potters sought desperately to discover the secret. The first factory to make porcelain in the Oriental manner was at Meissen in Saxony, patronized by Augustus the Strong, but soon many small factories began to spring up in Germany, Austria, and Italy. France had several factories making a modified type of porcelain, the most important being the Sèvres factory, owned by Louis XV and patronized by his mistress, Mme de Pompadour. The first English factory, at Chelsea, was established as late as 1745. Porcelain was probably the most important expression of the Rococo style in the first half of the 18th century, with bronze and goldsmiths' work closely following in second place; indeed, this period might well be called the age of porcelain. Rooms entirely decorated with porcelain still exist. These included not only vases and figures, but also mirror-frames, scrollwork, cornices, and even small console tables. A very fine example still survives at the Palazzo di Capodimonte (Museo e Gallerie Nazionale di Capodimonte) in Naples.

The French style developed, in the 18th century, into a very skillful synthesis of materials in which bronze and porcelain played an important part. Furniture was elaborately mounted in bronze with a marble top and was often decorated with porcelain plaques, as well. Clocks were made from porcelain vases. Jardinieres and vases were filled with porcelain flowers with bronze stalks and leaves. Veneering with rare woods reached its height, and decorative marquetry, often elaborately pictorial, was practiced. Much sought at this time was the marquetry of brass and tortoiseshell, which began with Boulle, although it was a revival of an Imperial Roman fashion. Tapestries covered the walls when these were not decorated with carved wood-panelling known as boiserie. Another form of wall-decoration, also employed in the making of furniture, was vernis Martin (Martin's varnish), an imitation of Oriental lacquer that was extremely popular after 1730. The large *salon de reception* of the 17th century gave place to smaller, more intimate rooms, and more of them, and the furniture and decoration of the period are also on a smaller scale.

The Rococo style is remarkable for its flowers and its curves. Furniture legs were gracefully curved, and tops were cut into serpentine shapes. It is easy to see when the Rococo style ends, because chairlegs at once become straight.

Typical Rococo features are seen in the interiors of the architect and decorator Germain Boffrand for the Hôtel de Soubise, Paris (begun 1732), where architectural form has been subordinated to the demands of the decoration; the cornice has disappeared, and walls curve into the ceiling, appliquéd with ragged C scrolls, garlands of flowers decked with ribbons, sprays of foliage, trellising, and shell motifs. The reduced scale of rooms and the reaction from monumental design result in elimination of the classical orders. Relatively small painted panels, idealizing peasant life, were enclosed in flattened moldings, silvered or gilt; pastel-coloured backgrounds prevented the smaller size of the salons from becoming too evident. The use of Chinese motifs typifies the search for novelty and blends well with the general lightness of style. The Cabinet de la Pendule (Room of the Clock) at Versailles (1738), designed by J. Verberckst, is another excellent example of French Rococo interior design. Gilles-Marie Oppenordt and François de Cuvilliés also were distinguished designers who worked with the best artists and craftsmen of the time.

The Rococo fashion spread across Europe to the courts of minor royalties, where many Frenchmen were employed to provide up-to-date buildings and schemes of decoration. In France the Gobelins factory became restricted mainly to the output of tapestries; equally fine work is seen in Aubusson and Beauvais carpets and tapestry. Improvement in glass manufacture resulted in larger mirror panels and brilliant crystal chandeliers.

Neoclassicism of the Louis XVI style

The Louis XVI, or Neoclassical, style began, in fact, to take root before the death of Louis XV in 1774; Mme de Pompadour and her brother, the Marquis de Marigny, were among the first to be attracted by the new classical style in the 1750s. From 1748 onward the characteristically French regard for formality was stimulated by the archaeological discoveries at the sites of the ancient Roman cities of Herculaneum and Pompeii and by the other surveys of classical remains published at this time.

It is sometimes forgotten that contemporary English styles also had influence in France, mainly through the published works of the architects Robert and James Adam. The asymmetrical, sinuous lines of the Rococo were slowly replaced by a more restrained form of decoration based once again on straight lines, right angles, circles, and ovals, arranged symmetrically. The lightness and fine moldings were retained, but the decorative forms were once more contained by the architectural framework. New motifs, many of them selected from antique Roman wall painting, decorated the panelling, in paint or in flat relief; palmettes, husks, urns, tripod stands, sphinxes, trophies of arms or musical instruments were frequently combined in the decorative schemes (Figure 29). Gilt bronze was used with wood and plasterwork for moldings and ornamental

fillets, emphasizing the rectilinear character of the design. The work of J.-A. Gabriel in both the Chambre du Conseil at the École Militaire (begun 1751) and the Galerie Dorée, Ministère de Marine (begun 1762) may be cited as Parisian examples. The keynote of colouring, as well as design, is refined simplicity. Silk tapestry wall hangings with fine flower and ribbon motifs appear in pale blues, greens, rose, and lilac. Similar colourings were used for satin and velvet upholstery. The fine wood carving of the brothers Rousseau, gilt bronze work by Clodion (Claude Michel),

and furniture pieces by David Röntgen, C.E. Riesener, and Jean Oeben show Louis XVI decoration at its highest. Apartments for Queen Marie-Antoinette at Versailles and her boudoir at Fontainebleau are full of this extravagant delicacy, soon to be obliterated in the French Revolution.

Spain. In Spain, Moorish influence mingled with subsequent Western classical styles to produce a unique flavour in decorative design. The style known as Mudéjar (*c.* 12th–17th century) was the early outcome of these blended Christian and Arab ideas and consists in essence of tiled floors and skirtings in polychrome (Figure 30), plain white walls, carved stucco friezes, and intricately decorated beamed wooden ceilings. The Duke of Alba's palace, Seville, contains fine interiors decorated in this style.

The Mudéjar style

Yellow tiles decorated with freehand motifs in blue became common in the 16th century. Tiles were often used on the ground floor of summer living rooms. Since fireplaces were seldom used in southern Spain, these rooms were vacated in the winter for the upper rooms.

The discovery of the New World, with the riches Spain subsequently drew from Mexico and Peru, created a period of Spanish ascendancy in the 16th century that encouraged building and coincided with the spread of Renaissance ideas throughout Europe. The influence of decorative craftsmen from Italy, together with the abundance of precious metal, encouraged the development of Plateresque ("silversmith-like") decoration. This type of Renaissance decoration was first seen in church interiors, in the form of tombs, *retablos* (a decorative structure behind an altar), and ironwork screens. The Italian motifs were used in a totally non-Italian manner, encrusting the surfaces as in the late Gothic or Mudéjar style.

This unique Spanish blend of widely separate styles produced the fine interiors of the late 15th-century Panteón de los Duques del Infantado, Guadalajara, by Vazquez, and the Palacio de Peñaranda de Duero (*c.* 1530), probably by Francisco de Colonia, where interlaced ceiling beams and timber panels were supported on honeycomb cornices and finely ornamented friezes. (Unfortunately, much of this work is now damaged or destroyed.)

Smaller houses as well as palaces were built around a patio, usually colonnaded and with modelled or carved friezes, columns, and bracket capitals.

Window grilles, or *rejas*, often form an important part of the decorative scheme, the ironwork being traditionally of a high degree of excellence. Love of closely patterned decoration, enveloping all surfaces that could easily be carved or modelled, is an important characteristic of early Renaissance work in Spain, and of the contemporary Manueline style in Portugal. Similar, if rather coarser, work in this style flourished in the American colonies.

High Renaissance decoration in Spain was influenced deeply by the austere character of Philip II and his vast combined palace and monastery, El Escorial (1559–84), near Madrid (Figure 30). This was built for him by Juan Bautista de Toledo and Juan de Herrera. Much of the granite of which the monastery is built is left unadorned, and frescoed vaulted ceilings are the main decorative features of interior design.

A revival of decorative arts took place in the late 17th century under the influence of José Benito Churriguera, his family and followers. The Churrigueresque, which also remained a peculiarly Spanish style, expressed the Baroque feeling of the 17th century in extravagant polychrome. Surfaces were broken into scrolls, rosettes, volutes, and fantasticated moldings; bunches of fruit and flowers hung from broken or inverted cornice moldings; and the whole interior—for example, the Sacristy of the Cartuja, Granada (1727–64)—appears to drip with ornament. Here, even cupboards and doors were inlaid with silver, tortoiseshell, and ivory, and the only plain surface is the checkerboard tiled floor. Remarkable among domestic examples of this style is the Palacio del Marqués de Dos Aguas, Valencia (1740–44).

The Churrigueresque style

Under the Bourbons, French and Italian influence increased, as can be seen in the interiors of the Royal Palace at Madrid (1738–64), with its handsomely painted ceilings and brocade wall hangings. Here, also, subsequent changes of taste are echoed in the lighter Rococo treatment of the Gasparini Saloon. Toward the end of the 18th century the Neoclassical movement gained a limited footing, though regional styles continued to incorporate the Baroque and older forms.

Fine examples of Spanish colonial work exist in Mexico, Peru, and other South American countries where the Baroque was allied, as in Europe, with the Jesuits. Churches are painted and gilded with an exuberance equal to or even greater than that found in the mother country. Sometimes the churches are encrusted with tiles, and they always possess elaborate *retablos*.

Northern Europe. After spreading from Italy to France, Renaissance influence began to filter to Belgium and Holland, later reaching the various Germanic states and finally dying out in Scandinavia and Russia.

In the Low Countries and northern Germany during the 16th-century Renaissance, ornament was adapted to form an entirely individual style, which can be seen in the pattern books of the artists Hans Vredeman de Vries and Wendel Dietterlin. Strapwork (interlacing bands) and raised faceted ornament were widely employed, together with muscular, grotesque masked caryatids and distorted architectural features arranged in undisciplined designs (Figure 31). Chimney pieces, with overmantels carried to the ceiling, were embellished with marble columns and elaborate strapwork patterns, while similar ornaments flanked the doorways and enriched the ceilings. The great tapestries for which the Netherlands had long been famous were still in use, and Oriental carpets were spread as table covers and not used on the floors. Many town houses and civic buildings were comfortably appointed, yet without spectacular extravagances, and give an impression of modest prosperity. In Belgium the Musée Plantin-Moretus, Antwerp (1550), is unusually richly decorated, showing the influence of Spanish rule in the use of embossed leather as a wall covering. Large windows, with rectangular leaded lights, are again typical of a northern climate. Ceilings are beamed or plastered, and floors most frequently are of tiles on the ground floor and timber on upper floors.

Use of strapwork

The later styles of Baroque and the 18th-century tastes are copied from French models, particularly in Belgium. The Dutch, after achieving independence in the latter part of the 16th century, developed their decoration on more individual lines. Typical domestic interiors on a small scale are familiar through the paintings of the 17th-century artists Jan Vermeer and Pieter de Hooch (Figure 32). The fine series of town houses by Daniel Marot and his sons in The Hague illustrate the cross-currents of the various styles; built at the turn of the 17th century, they were conceived in the Louis XIV, or Régence, manner, yet could

Marot town houses

Figure 31: Strapwork and facetted ornament: Swiss Renaissance room from the Rosenburg at Stans, Switzerland, 1602.
By courtesy of the Musee National Suisse, Zurich

be set down in 18th-century London without incongruity (and Marot did, in fact, work for a time in England). Fine stuccoed ceilings and overdoors, largely uncoloured, and wrought iron balustrading are characteristic.

In Germany the general trend was similar, but in southern Germany and Austria fresh impetus and individuality were given to Baroque and also Rococo design. French and Italian craftsmen worked throughout the 17th century on the many Catholic churches built in south Germany, Austria, Bohemia, and Moravia. The use of colour, fresco, and stucco that they introduced has its own particular flavour when seen in cool northern light (see Figure 12, left).

Secular building from the early 18th century, in the hands of such architects as Johann Lucas von Hildebrandt and Johann Bernhard Fischer von Erlach, makes use of much sculptural detail. Windows are round or oval, figures strain to support capitals, balustrades are carved in sculptural manner, and modelled niches contain larger than life-sized figures; all these give a feeling of movement reminiscent in its impact of Bernini's work in Rome. Another characteristic was the enormous staircase hall, or *Treppenhaus*, which was one of the most notable interior features of German and Austrian Baroque and Rococo architecture. In the halls, colour was frequently confined to the painted ceilings, giving increased force to the novel and delicious colours of the rooms beyond. A vermilion dado or olive-green panels may be contrasted with white and gold. In the Nymphenburg Palace, near Munich (1734–39), by the Frenchman François de Cuvilliés, the Rococo reaches its crowning achievement: mirrors are framed in freely scrolled moldings, which in their turn are interspersed with trellising, garlands, baskets of fruit and flowers, cupids, birds, and fountains in silvered stucco on a pale blue or yellow ground, the whole evoking the essence of pastoral Romanticism (Figure 33).

Scandinavian interiors

Mingled influences from France, Holland, and England reached Sweden and Denmark in the mid-17th century and are seen in the Baroque and Louis XIV interiors of the Riddarhuset and Royal Palace in Stockholm and in the chinoiserie (Chinese-influenced decoration) of the Royal Palace of Drottningholm. Scandinavian interiors, however, largely continued to be of the traditional exposed timber boarding, hung perhaps with painted linen panels and brightened by woven chair and cushion coverings (Figure 34).

Russia imported foreign designers and styles in the late 17th and 18th centuries for the palaces built under the westernizing influence of Peter I the Great, his daughter Elizabeth, and Catherine II the Great. In the mid-18th century the Italian Bartolomeo Francesco Rastrelli designed the Tsarskoye (Detskoye) Selo (now called Pushkin), Peterhof, and Winter palaces in or near St. Petersburg, and A.B. Kvasov, S.I. Chevakinsky, and Rastrelli designed the Hermitage, also in St. Petersburg. Each worked largely according to his own current national styles. The same is true of the work of the British architect Charles Cameron at Tsarskoye Selo Palace and Pavlovsk Palace.

In many areas of Europe, Renaissance, Baroque, and Rococo had little effect on interior decoration. In the Alpine lands, where wood was cheap and plentiful, traditional medieval methods continued for a long time. Wooden floors and ceilings and panelled walls, or partly panelled with plain plaster above, were the general rule. The moldings were bold, but carving was usually in low relief and often the woodwork was painted in bright colours.

England. The breakup of the feudal system during the Wars of the Roses and under Henry VII in the late 15th century had far-reaching effects on the social structure of the time and consequently on domestic buildings and their decoration. The new conditions necessitated a larger number of rooms, and a great hall, though still an important apartment, was no longer the focus of indoor life. Wider distribution of wealth gave rise to numerous coun-

Gunther Schmidt—EB Inc

try houses, and for the next 400 years the English excelled in their building and decoration.

Adoption of Italian ornament

The Italian style reached England in the early 16th century; the earliest example is the tomb of Henry VII in Westminster Abbey, designed by Pietro Torrigiani of Florence at the command of Henry VIII and completed in 1518. For the next 40 years or so, English craftsmen borrowed from the repertoire of Italian ornament, at first inspired by and imitating the Italian artists and craftsmen employed on royal works at Hampton Court Palace, Middlesex, and the Palace of Westminster, London, who used arabesque decoration, medallion heads, and amorini on panelling and plasterwork, often mingling them with the traditional Gothic motifs. The great hall at Hampton Court (1515–30) shows a combination of Renaissance carved and gilded detail with the traditional type of open timber roof, known as the hammerbeam roof, and windows divided into sections by vertical posts (mullions). In spite of Henry VIII's example, however, the Gothic style died hard in England, lingering in the remoter districts well into the 17th century.

During the second half of the 16th century, as a result of the break with Rome, the Italian style was largely replaced by the distinctive Renaissance style of the Low Countries and Germany, fostered by the close religious, political, and economic relations between England and the Low Countries, the influx of immigrant workmen, and the circulation of Flemish and German pattern books. This new manner became the dominant influence in the decoration of panelling and plasterwork, characteristic features being intrinsic strapwork patterns, pyramid finials (sculptured ornaments used to terminate roof gables), raised faceted ornament, masks and caryatid figures, scrolls, and pilasters. Both the Italian and Flemish styles were adapted and naturalized to some extent by the English craftsmen, producing a new style that is peculiarly English.

At this time, also, the internal porch was introduced into many houses; this device excluded drafts from the room and also in some cases made it possible to reach a second room without passing through the first.

The frescoing of walls continued; of the few remaining examples, some show scenes from biblical and classical sources and incidents from local folklore. A good Elizabethan example depicting scenes from the story of Tobit was found at the White Swan inn at Stratford-on-Avon. Embossed, painted, and gilt leather was less used in England than on the Continent, but tapestries and such woven fabrics as velvet and damask for the wealthy and "says" (fabrics resembling serge) and "bayes" (baize) for people of more modest means were widely used as wall coverings. The inventories of Henry VIII's palaces show the vast number of tapestries and various hangings possessed by kings and great men. Hangings of painted cloth were widely used as a cheaper substitute for tapestry; these, too, depicted incidents from biblical and classical sources and employed decorative motifs ranging from Gothic to Renaissance subjects. Nearly all of this "counterfeit arras" has perished. The plaited rush matting continued to be used as a floor covering in Elizabethan interiors.

Tudor wall decoration

Great chambers and long galleries, usually on the upper floors, are distinctively Elizabethan or Tudor and were used in many cases for work and recreation in bad weather (Figure 35). Barrel-vaulted ceilings occupying the roof space often increased the height of the rooms, as at Chastleton House, Oxfordshire (*c.* 1603). The plaster ceilings were treated elaborately; narrow interlaced bands formed geometrical patterns, with semistylized floral, arabesque, or heraldic motifs in the panels between.

The steep medieval winding newel stair (stair with central pillar from which steps radiate) in wood or, more often, stone was abandoned for the more spacious staircase with straight flights of stairs, easier in gradient and planned round an open well. This was most frequently constructed of oak, with carved newel posts (the upright terminating a flight of stairs) and balusters (individual columns in a balustrade) making the most of the opportunity offered for decoration and enrichment.

Staircase design

Toward the middle of the 16th century, a feeling for classic reserve was spreading and the late Renaissance period might have flowered under Charles I had not political upheaval checked the zest for fine building. The architect and stage designer Inigo Jones twice visited Italy and was one of the few north European architects completely to absorb the spirit and decorative repertoire of Italian Renaissance classicism. He introduced the new style in the Banqueting House at Whitehall, the Queen's House at Greenwich; and with his associate and kinsman, John Webb, built Wilton House, Wiltshire.

At Wilton the Double Cube Room (*c.* 1649) shows the nobility of effect Jones was able to achieve in a small compass, for the dimensions of the room—60 by 30 by 30 feet (18 by 9 by 9 metres)—are not large, comparatively speaking (Figure 36). The basic influence

is Italian, but the final result—with wide oak-boarded floor, and white- and gold-plastered and panelled walls designed to accommodate portraits by Van Dyke, the white marble fireplace, and the Corinthian doorcases—is truly English. The coved and painted ceiling, executed by Edward Pierce and Emanuel de Critz, plays a vital part in balancing the proportions of the room. Though Renaissance principles are demonstrated in design such as this, they were not fully developed in the country at large until the 18th century and the advent of the Palladian school of architecture and decoration (influenced by the 16th-century Italian architect Andrea Palladio).

After the unsettled period of the Commonwealth, the Restoration introduced new Baroque influences from the Continent. These were fused with the restraining classicism (which was still considered to be a new style) to produce a successful balance of contrast. The designs of the great architect Sir Christopher Wren, though mainly for church and monumental buildings, relied for a great deal of their embellishment on the work of the fine artist-craftsmen such as Grinling Gibbons, sculptor and wood-carver, and Jean Tijou, ironworker, whose work can be seen in close association in St. Paul's Cathedral. In the many country houses, large plain-surfaced oak wall panels provided the perfect foil to the grace and liveliness of Gibbons' carved limewood swags (festoons), garlands, and picture borders, which incorporated flowers, fruit, musical instruments, cherubs, and monograms. In the words of the 18th-century writer Horace Walpole, Gibbons "gave to wood the loose and airy lightness of flowers, and chained together the various productions of the elements, with the free disorder natural to each species." At Petworth house, Sussex, Gibbons' genius may best be seen in the series of perfectly executed picture borders, which date from about 1690. Chimney pieces and doorcases were also decorated in Gibbons' manner, and similar floral motifs can be seen on the plaster ceilings at Ham house, Wiltshire. This house, relatively modest in size, represents without ostentation or extravagance the height of luxurious interior decoration in the late 17th century and incorporates many of the decorative innovations of that time. Among these are the practice of painting wood panelling in imitation of marble or wood graining and of gilding the moldings. Wall hangings include tapestry, gilt and painted leather, and silk damask; there is elaborate parquetry (floors inlaid with woods in contrasting colours).

Decorative genius of Grinling Gibbons

Paintings of allegorical subjects by Sir James Thornhill and Antonio Verrio ornament some of the more important buildings of the age, including the Painted Hall at the Royal Hospital in Greenwich, Wren's additions to Hampton Court, and the great chamber at Chatsworth House, Derbyshire. The intricate work of Daniel Marot, a French Huguenot architect who had worked for William III in Holland (see above *Northern Europe*), had a modest influence on the design of many small fittings and shelved

cabinets to display china—the collecting of which was a favourite pastime of Queen Mary II. Imported lacquer panels were sometimes used for the panelling of rooms, in accordance with the Chinese taste of the period.

In the last years of the 17th century and in the early 18th century the woodworker found his domain contracting. Through the influence of the grand tour and under the patronage of Lord Burlington, Italian influence predominated, the work of Inigo Jones was studied, and stone and stucco became more widely used, particularly in larger houses. The influence of the architect spread from the outside of the house to the interior decoration and even to the design of the furniture itself. Where wooden panelling was used, it was set in a simple framework. Pine largely replaced oak, and it was painted green, blue, brown, and other colours; walnut and mahogany were occasionally used for panelling. The increased use of stone and marble began with Sir John Vanbrugh, playwright turned architect, who, in his first commission at Castle Howard, Yorkshire (1699), showed an individual and masterly interpretation of Baroque, sculptural and yet with a certain grim epic quality. Applied decoration was kept to a minimum, a practice that he followed later at Blenheim Palace, Oxfordshire, where the severe and spacious entrance hall, with marble-paved floor, ashlar-faced (*i.e.*, faced with thin slabs of hewn stone) walls and columns, wrought-iron gallery railing, and frescoed dome, is the most impressive apartment in the building.

Stone staircases with wrought-iron balustrading came into common use, and by the latter part of the 18th century had almost entirely replaced the earlier, heavier timber stairs such as those at Wolseley Hall, Staffordshire, or Eltham Lodge, Kent, which had carved openwork balustrades or heavy timber balusters. In the smaller houses of the early 18th century, woodwork continued to provide the main decorative features. Wall panelling, moldings, window shutters, and many chimney pieces in simple painted pine echoed the comfortable elegance of the tall sash windows and well-proportioned rooms. Wealthier classes still employed Italian craftsmen, particularly for stuccowork, and the now familiar repertory of garlands, masks, and putti (cupids) was applied not only to the designs of Nicholas Hawksmoor, James Gibbs, and other architects of the quasi-Baroque group but also to the interiors of William Kent and the Palladian architects, whose influence became dominant toward the middle of the century (see Figure 13). In such houses as Holkham Hall, Norfolk, designed in strictly classical manner by Kent in 1734, can be seen the results of extensive travel by both architect and owner. The magnificent entrance hall is again one of the most important rooms, designed on the general lines of a Roman basilica with apse (recess) and side colonnades. At Houghton hall, also in Norfolk, Kent designed fine suites of furniture for Colin Campbell's interiors; these pieces are usually gilt, with acanthus scrolls, consoles, heads, and sphinxes; with feet and legs scrolled or of ball and claw type; and with upholstery in velvet or silk. The plaster ceilings are by Italian craftsmen, with gilded and painted ornament; the walls are dressed with classical plinth, pilasters, and frieze; and pedimented marble chimneypieces contain bas-relief panels above the mantelshelf.

Continuing use of wood in the 18th century

Wall hangings were of tapestry, cut velvet, or watered silk and damask. Elsewhere, hand-coloured, wood-block-printed papers and papers with flocking (pulverized cloth) were coming into use as an economical substitute.

Although the Rococo style never fully established itself in England, many interiors were influenced by the asymmetrical motifs (rocaille) found in the designs of such French decorators as Nicholas Pineau and J.A. Meissonier. The stucco and carved decoration became lighter, more fanciful, and more tortuous in design. Though many Baroque motifs were still used, they were more delicately modelled, and the Rococo style was characterized by elaborate patterns of interlacing C scrolls combined with such naturalistic ornaments as flowers, foliage, shells, and rocks, arranged subtly in asymmetrical yet balanced patterns. The plasterwork and carved panelling were often painted in light colours and the detail picked out in gold.

Closely allied to the introduction of the French rocaille was the revival of the Chinese taste, or chinoiserie, for architects and designers, in search of further novelty, turned again to China for inspiration. Books on travel and topography, notably Jean-Baptiste du Halde's *General History of China*, published in Paris in 1735 and translated into English in 1736, gave added stimulus. Pagodas, mandarin figures, icicles and dripping water, and exotic foliage and birds reached the height of Rococo invention. Chinoiserie was particularly popular for bedrooms, where elaborate chimneypieces and doorcases were set against the background of imported or imitation Chinese wallpapers, and the beds and windows were hung with Eastern textiles. Window hangings, with carved and gilded pelmets (valances), were becoming increasingly important, and at Harwood House, Yorkshire, the furniture designer Thomas Chippendale executed a series of pelmets with mock draperies also carved in wood and coloured to deceive the eye completely.

Popularity of chinoiserie

The Gothick taste, a further variation of the Rococo, was peculiar to England at this time. The Gothic Revival, engendered by antiquarian scholarship at the turn of the 17th century, later spread to literature and during the 1740s appeared in the more concrete forms of architecture and interior decoration. By the middle of the century the fashion was widely popular, and many houses, large and small, were in part Gothicized, both inside and out. As with chinoiserie, the products of this 18th-century vogue bore little resemblance to the original medieval models. Gothic details, originally worked in stone, were borrowed, adapted, often mingled with rocaille and Chinese motifs, and were executed in wood and plaster. At Strawberry Hill, Twickenham, Middlesex, Horace Walpole, leader of the "true Goths," borrowed the designs of medieval tombs and turned them to designs for fireplaces and bookcases. Though this vogue fell out of general fashion in the 1760s, a few enthusiasts remained who carried the Gothick taste through until it was vigorously revived again in the 19th century.

Gothick taste

About 1760 the Rococo style, with all its vagaries of taste, began to give way before the Neoclassical style, largely inspired and introduced by the architect Robert Adam, whose work reflected the newly awakened interest in classical remains. Adam returned from Italy in 1758, and, strongly influenced by both Roman architecture and interior decoration, he evolved a new style based on classical precedent, using as ornament a medley of paterae (plate-shaped motifs), husk chains, the ram's head, the formalized honeysuckle, and other elements. His style of interior decoration was deeply influenced by the gay and delicate patterns of arabesques and grotesque ornament that he had seen in various classical remains in Rome and that had already been copied during the Renaissance by Raphael and others. Adam strongly criticized the Burlington (Palladian) school for using heavy architectural features in their interiors and replaced them with delicate ornament in plaster, wood, marble, and painting, against which, in its turn, criticism was levelled. Much of his work, it may be said, is applied decoration—pretty but without basic architectural quality. With Adam, the despotism of the architect over the craftsman was complete. No detail of decoration or furnishing escaped him; his rapid and precise draftsmanship covered the whole scheme, from the overall treatment of the walls and ceiling to the decorative details of the pelmets and grates. Even carpets were made to order, and often they repeated or echoed the design of the ceiling, bringing the whole room into harmony, as in the green drawing room in the manor house of Osterley Park in Middlesex or in the dining room at Saltram House in Devonshire (Figure 37). Wood was not often left unpainted, and, although the joinery was still admirable, the enrichment was frequently in composition or metal inlay. There were especially designed templefronted bookcases, and the plasterwork was often made a frame for the decorative paintings of such artists as Antonio Zucchi or Angelica Kauffmann.

Contributions of Robert Adam

At this time, cheaper and quicker methods of decoration began to be introduced; a considerable amount of the plaster decoration was cast from molds, and a composite imitation marble called scagliola was sometimes used for

Figure 37: Neoclassical early style dining room at Saltram House, Devon, designed by Robert Adam, plasterwork and paintings by Antonio Zucchi, 1768.
A. F. Kersting

floors and columns, while cheaper woods were disguised by marbling and graining.

At the close of the century the Neoclassical style was further refined, the plaster relief decoration being simplified and lightened. The best of this style, strongly influenced by French decoration, can be seen in the work of the architect Henry Holland, who enlarged Carlton House, London, for the Prince Regent and built Southill in Bedfordshire. Holland, like Adam, was inspired by the classical monuments in Italy, where for some time he maintained a draftsman whose drawings of classical detail Holland incorporated in his plasterwork.

United States. The story of the domestic interior and its decoration in the United States is inseparable both from its own architectural development and from the story of English architecture and decoration, from which it was largely derived even long after the American Revolution. Any discussion of United States decorative design, therefore, must refer constantly to the architectural ideas that prompted change on both sides of the Atlantic Ocean.

Early domestic interiors

Contrary to popular legend, the log cabin was not the earliest shelter of the first English settlers. The turfed-over dugout hut of mud-chinked saplings, not unlike the Indian wigwam with the addition of a clay-daubed wooden chimney at one end, was probably the first home of the settlers in both Jamestown and Plymouth.

These primitive dwellings were speedily replaced by frame structures, copying the traditional small house of southeast England. At first a single room was flanked by a massive chimney (where brick quickly replaced wood and clay), but a second room was soon added on the opposite side of the chimney. The attic, later expanded into an overhanging second story, was reached by narrow winding stairs between the central entranceway and the chimney stack.

This development in New England is well represented by such vestiges as the Capen House, Topsfield, Massachusetts (1683) or the Old Iron Works (ironmaster's) House, Saugus, Massachusetts (1636). The interior clearly reflects the structure, with its massive exposed oak corner posts, beams, and joists and its huge open fireplace, which served as the cooking and heating centre of the household. Inside walls were usually of undecorated lath and plaster, covering the studs and their clay or brick filling. Windows were small and originally of casement type, with small leaded panes in a wood frame. Small windows with low ceilings conserved heat in the severe winters. Floors of wide riven boards of pine, smoothed and sanded, replaced the beaten clay of the first shelters (Figure 38).

The furniture, with few exceptions, was simple and sparse. It was decorated with simple carved and turned ornament and touches of earth colours.

By the end of the 17th century, homespun textiles were supplemented by imported woven materials in the houses of the more affluent; these were used for curtains, table covers, bed hangings, and seat pads. Richly coloured damasks and velvets, enhanced by the unpainted wood and plaster surfaces, were found in Puritan New England and, probably to a greater extent, among the less austere New York Dutch and the comparatively wealthy tobacco planters of Virginia.

In houses south of New England, brick and stone tended to replace wood as a building material, though there were many smaller timber structures that have largely disappeared. In the Hudson River region, the traditional cottage of the Flemish and Huguenot settlers, long and low with steep pitched roof and extended eaves, became the typical farmhouse. At the same time, the narrow Dutch town house of brick with its stepped gable ends gave New Amsterdam, even after the English occupation, an appearance completely different from that of the English settlements to the north and south.

In the Dutch houses, windows tended to be larger and ceilings higher. The early fireplace, with its tiled border, surmounted with a deep hood, was flush with the wall instead of deeply recessed. Dutch features such as the horizontally divided door, the monumental cupboard, or *kas*, the built-in bed, and tiling and dishes of delftware gave the early New York interior an individuality that withstood English influence until well into the following century.

Dutch features in New York

Similar national characteristics must have distinguished the early Swedish settlement on the Delaware, where, later in the century, the log cabin of the pioneer may have first appeared. The Swedish contribution was only temporary, for the settlement was absorbed by both the Dutch and the English. The early settlements of the English in east New Jersey were founded by migrants from New England who at first designed typical central-chimney houses but before the end of the century largely abandoned them for the Flemish type of house in the neighbouring Hudson River region. The first settlers in Pennsylvania, arriving in Philadelphia at the end of the century, built the type of town dwelling devised for the rebuilding of London after the Great Fire of 1666.

In Virginia and the South, scant evidence remains of the early 17th-century house. Bacon's Castle in Surry County, Virginia, with its projecting two-story porch in front and

Richard Merrill

rear stair tower, built in brick about 1665, is all that remains of a colonial version of the small English Jacobean manor, though there must have been several other examples. From surviving evidence and deduction it is believed that panelled walls, carefully designed beamed ceilings, and ornamental plasterwork in colour were employed in larger Virginia houses. Yet, while the milder climate made loftier ceilings and larger rooms possible, it is unlikely that the ordinary early dwelling differed from its Northern contemporary except in its greater use of brick and in placing chimneys at the ends instead of at the centre of the structure.

Among the wealthy the principal articles of furniture were undoubtedly English imports; the more humble settler probably had to make do with articles of the simplest sort, but since few articles survive from this period, little is known about it. Certainly the scattered or rural character of the Southern settlements and their concentration on tobacco planting failed to encourage the early development of skilled crafts found in villages and towns of the Northern communities. By 1720 the design innovations of Inigo Jones and Sir Christopher Wren, as reflected in the Queen Anne style with its strong mingling of Dutch and Flemish elements, had already crossed the Atlantic. Wren's influence is increasingly evident in the tendency to employ symmetrical design around an accented central feature and, particularly in the interiors, in the greater insistence on classic arrangement in the positions of openings and of panelling. Panelling, usually of pine in the north, was generally painted. Relatively deep and strong tones—red, blue, green, brown, and yellow—were used either singly or in combination, producing an effective background for the walnut furniture of the period.

Influence of Wren and Jones

Additional colour was introduced by more elaborate use of woven and embroidered textiles, in upholstery as well as draperies. Though woven carpets for floor coverings were rare even at midcentury, frequently their effect was achieved by stretched canvas painted with allover repeat patterns.

Throughout the colonies, furniture became more plentiful and varied. Chairs without arms took the place of stools, the cabriole (curved leg) largely replaced the turned leg, and small drop-leaf tables replaced the fixed-frame type. Bedroom furniture became differentiated with the development of the high chest (highboy) and the dressing table (lowboy), and later the case-top desk or secretary became the principal ornament of the living room. Tall mirrors with crested tops replaced the small, square, Jacobean style looking glasses of the 17th century, and portraits and prints came into more general use, sharing the wall space with bracketed candle holders or sconces. Artificial light still came mainly from small wick and grease lamps, but tallow and wax candles held in sconces, in adjustable metal and wood floor stands, or in candlesticks of brass or pewter (and occasionally in brass chandeliers) were used by the wealthier.

Colonial furniture

Though domestic comfort was improving, north of Virginia the large formal house or mansion remained a rarity until about 1750. In the South the wealth of the slave-holding planter made it possible for him to copy the early Georgian type of manor house in England. Great houses of two or three stories with side dependencies (outbuildings) became numerous. Stratford in Westmoreland County and Westover in Charles City County, Virginia, built about 1735 by the Lee and Byrd families, are early examples of the type. The elaborately panelled rooms of these mansions were furnished according to the latest London fashion. Probably only later in the century were these English pieces mingled with those from the cabinetmakers of Philadelphia, New York, and Boston. Between 1750 and the Revolution this Georgian phase reached its highest development. Though generally smaller and lacking the forecourt and dependencies of the southern mansion, the larger houses of the north, such as the Wentworth house in Portsmouth, New Hampshire, mark perhaps the most distinctive achievements of colonial design and decoration by their apt translations into wood of brick and stone Georgian forms.

In the Middle Atlantic colonies, particularly in Philadelphia (which by 1760 had assumed urban leadership in the colonies), a type of domestic design midway between that of New England and Virginia had developed. There the English Rococo decorative style publicized by Thomas Chippendale received its most competent and original interpretation. This is well seen in Philadelphia interiors such as those of the Powel House (1765) and Mount Pleasant (1762) and in the work of cabinetmakers such as Thomas Affleck and Benjamin Randolph (Figure 39). By this time mahogany, with its fine grain, so receptive to carving and high finish, had largely replaced walnut as the principal cabinet wood. Inspired by this material and the challenge of London design, these Philadelphia craftsmen and their northern contemporaries, particularly John Goddard and Job Townsend of Newport, Rhode Island, brought their art to the highest level of perfection.

English Rococo in Philadelphia

Figure 39: Middle Atlantic adaptation of the English Rococo style using Philadelphia Chippendale furniture: Great Chamber at Mount Pleasant, Philadelphia, 1762.

During the third quarter of the 18th century, the panelled interior reached its most elaborate form in the colonies. North of Virginia a fully panelled room was exceptional; wood panelling was reserved for the chimney breast and its flanking recesses or cupboards. In Virginia and the South, full panelling remained the rule. (At colonial Williamsburg, Virginia, surviving houses have been carefully restored and furnished, giving a complete picture of the comfortable panelled rooms dating from the middle decades of the 18th century.) In both North and South, however, the mantel and its overmantel were emphasized as a decorative unit, and the Baroque broken pediment became the usual crowning feature of both overmantel and doorway. Painted woodwork remained popular, but with softer and lighter tones, tending toward white and gray. Plaster wall surfaces were also painted. Block-printed and painted wallpapers were frequently used in the main rooms of these houses, and there are indications that fabric wall hangings were used also.

Plaster ceilings completely concealed the floor beams by the second quarter of the century, and after 1750 these were frequently decorated with ornament in low relief in the French or Rococo manner and hung with many-branched chandeliers of crystal. Floors of hardwood, occasionally parquetry, were more frequently covered with patterned rugs of European or Oriental origin.

During the 18th century imports of printed cottons or chintz in the Indian taste, and silk brocades and damasks, largely replaced the linen and woolen weaves of earlier days. Upholstered furniture, wing chairs and sofas, and elaborate draperies increased still further the richness of the fashionable interior.

Use of textiles

As in Europe, the growth of tea and coffee drinking encouraged production of suitable silverware and the import of English and Oriental porcelains, which required corner

Figure 40: Roman decorative motifs characteristic of the Empire style: bedroom of the empress Josephine in the Château de Malmaison, near Paris, 1810.

and wall storage cupboards. Demand was also created for a variety of small movable tables and stands for tea and coffee services.

During this century the German settlers in Pennsylvania added their traditional styles of design to the dominantly English tradition of the colony, the effects being more evident in folk arts than in formal decoration. It was to this style and its development after the Revolution that the first American decorative glass of Henry William Stiegel and Frederick Amelung must be credited, as well as most of the decoration on early American pottery.

19th and early 20th centuries in Europe. Neoclassicism predominated in France till the rise of Napoleon, when to Roman styles were added Egyptian motifs from his Egyptian campaign of 1798. This was known in France as the Empire style, after the First Empire of France (1804–14), and in England as Regency, for the period (1811–20) when George III was too deranged to rule. Furniture design, for the most part light and graceful during the early part of the Neoclassical period in France, had become more consciously luxurious as the Revolution was approached. During the Empire period it became massive, imposing, dark, and pompous (Figure 40). The usual vocabulary of classical ornament is to be found in both Empire and Regency, with some modifications from earlier times. The cabriole leg of the Rococo style became straight, and curves tended to disappear in all furniture. Symmetry of ornament replaced the asymmetrical curves. In England, in the latter part of the 18th century, porcelain became less and less fashionable, and its place was taken by the cream-coloured earthenware (creamware) of Josiah Wedgwood, and by his jasper and basaltes stonewares, all admirably adapted to the new style. Greek vase-shapes and classical ornament were commonly used in the decoration of Wedgwood wares of all kinds. In England, the work of Thomas Hope, a wealthy amateur architect, gained much attention through the publication of his *Household Furniture and Interior Decoration* (1807). He enlarged and decorated his London home in Duchess Street, Portland Place, and also his country house, Deepdene, in Dorking, Surrey, with somewhat heavy and pedantic design that was at variance with the general trend of the time but influenced later work.

In Germany the solid bulk of the Biedermeier style, with its thick curtains, draperies, antimacassars, and padded upholstery, gave evidence of material prosperity. Many of these features were to become commonplace in Victorian England, but in the meantime, the Regency style was prevalent and contributed many masterpieces of design. Brighton Pavilion (begun 1815) was built by John Nash for the Prince Regent. Much lacquered and bamboo furniture was used, blending with Chinese wallpapers, fanciful treatments of palm trees as columns, and the most extravagant of crystal chandeliers (Figure 41). In general, however, the Regency style strove for elegance without extravagance; innumerable smaller houses were built and decorated with fine wrought-iron balustrades on curving stone staircases, pleasing carved wood or marble mantelpieces of modest

The Regency style in England

sizes, and plain or panelled walls of light colouring, on which the use of wallpaper was becoming more common.

By the latter part of the 18th century, the Industrial Revolution was slowly developing, particularly in England, and machinery was increasingly producing many objects of interior decoration, modifying their form to suit the new methods and reducing the price to make them available to new markets, a situation envisaged by Wedgwood. The less affluent of the middle classes became the largest section of consumers, and manufacture was increasingly directed toward catering to their tastes.

Eclecticism as a style

In the early years of the 19th century a new concept was beginning to take shape—the notion of eclecticism, which propounded that any style was as good as another. This led to the idea that styles could legitimately be mixed together. In this way Horace Walpole's nightmare of a garden-seat—Gothic at one end and Chinese at the other—became, in principle, an accomplished fact: one firm, for instance, made a classical urn on a Gothic base.

In the early decades of the 19th century, in addition to the Empire and Regency styles, there was a Greek style of marked simplicity, and an Italian style described as 'picturesque with Palladian detail' (a contradiction in terms), as well as an "Elizabethan" style, a "Tudor" style, a "Baronial" style (under the influence of Sir Walter Scott), an "Abbotsford" style (also resulting from Scott's influence, based on his house of that name), and a revived Gothic style, far removed from Walpole's modest and amusing essay.

The Gothic Revival

The revived Gothic was at first inspired by James Wyatt's pseudo-cathedral built for the author William Beckford at Fonthill Abbey, with interiors of cathedral-like amplitude and about a 300-foot (90-metre) tower.

This Gothic Revival produced a small number of houses in which the pointed arch together with fan vaulting and crocketed (carved with foliated ornament) or deeply undercut moldings were used with some taste and discretion. Toddington Manor, Gloucestershire (1829), by the architect Charles Barry (who, with A.W.N. Pugin, designed the Houses of Parliament), and Hughenden Manor, the house of British prime minister Benjamin Disraeli, exemplify a style used later in the century with greater ostentation and coarseness of detail.

In the principal European countries, interior decoration grew increasingly heavy and elaborate. Ornament came to be considered synonymous with beauty, and pattern covered every possible surface. The products of industrial manufacture were mostly very crude, and their use resulted in loss of refinement; for example, aniline dyes, which are harsh in colour, were first made in 1856 and soon replaced the softer, more harmonious colours. Architects decked out their buildings according to whim in a variety of styles.

In less ambitious schemes of decoration brightly coloured wallpapers with bold patterns were widely used, and the white plaster ceilings were relieved by modelled cornices and often also by some central feature, frequently in a coarsened Rococo design, which made a background for the elaborate light fitting. Rooms became crowded with furniture, and fireplaces were often mounted with elaborate overmantels, fitted with mirror panels and a multitude of shelves and brackets for the display of knick-knacks. Both furniture and fittings were draped in dark-coloured plush with heavy fringes. Varnished pitch-pine dadoes, stained-glass windows, and encaustic-tiled floors were also popular.

By the 1830s there was a revival of Rococo, to be seen in the porcelain of the period and the chairs of John Belter of New York, and there was something called the "Louis XIV" style, which that monarch would have found difficulty in recognizing. Throughout this period there was a limited amount of pseudo-Chinese decoration, principally on pottery and porcelain and papier-mâché. After 1853, when Commodore Matthew C. Perry of the U.S. Navy reopened Japan to Western trade and influence, a new kind of Japanese art began to be exported, such as the vases of unprecedented ugliness decorated in Tokyo and called Satsuma, or enormous, grossly over-decorated vases from Seto in Owari (presently Aichi Prefecture), none of which would have found a buyer in the Japanese home-market.

Oriental Rococo

The 19th century was an age of eclecticism. Decorators introduced the custom of having a different style for each room—"Gothic," "Elizabethan," or "Old English" for the dining-room; "Queen Anne," "Chippendale," or "Louis XVI" for the drawing-room; with pseudo-Elizabethan furniture for the library. Design reached its nadir with the Great Exhibition of 1851, in London, the low-water mark in the history of European taste in interior decoration, from which there was no conceivable direction except upward.

In France, where there was a sounder tradition and Gothic had not been influential for centuries, 19th century taste was not quite so debased as in England. A light and amusing version of Gothic known as the Troubadour style made its appearance in the 1830s, perhaps an international tribute to the contemporary fame of Sir Walter Scott. Rococo was revived as the Pompadour style, and there was a neo-Renaissance period, with furniture designs based on 16th-century Italian work. On the whole, the furniture of the second empire (1852–70) was very acceptable in design, although these pieces were based largely on the 18th century; these styles harmonized well with the contemporaneous music of Jacques Offenbach and the brilliance of the court of Napoleon III.

In England there were a few people who recognized the depths to which taste had fallen. The designer and writer William Morris advocated a return to fine craftsmanship in furniture, textiles, and wallpaper, and started his own firm in 1861. Under the influence of the Pre-Raphaelite Brotherhood, artists who advocated a return to medieval principles, his furniture designs were based on actual surviving specimens instead of on Gothic architecture of the most florid periods. Morris's productions were well-made and well-proportioned, often with painted decoration in the old style (Figure 42). He helped to organize the Arts and Crafts Society with the object of improving design. His influence was limited, however, because, like his contemporaries, he looked backward for inspiration and in doing so refused to accept the possibilities of machine production.

Influence of William Morris

The 1870s and 1880s saw a fashion for reproductions of 18th-century furniture, especially the designs of Chippendale, Hepplewhite, and Sheraton, in which a few minor crudities, of a kind thought to be inseparable from handwork, were added to machine-production. Much of the "18th century" furniture that decorates today's interiors is no older than this vogue. A fashion arose in the 1880s for Japanese fans and screens and blue and white porcelain, in conjunction with bamboo and lacquer furniture, a taste to some extent influenced by the paintings of James Whistler.

The influence of Whistler, Morris, and others may be seen in the Art Nouveau style of decoration, which was developed in the 1890s by the Belgian architect and designer Henry van de Velde and the British designer Arthur Heygate Mackmurdo. This was a style in interior decoration which went under various names at the time—Art Nouveau in England, Modern Style in France, the Jugendstil in Germany, and the Stile Liberty in Italy, in reference to the influence of the London firm of Liberty & Co. in promoting the style. Art Nouveau was most reminiscent of Gothic, with overtones of the Japanese art imported during the last quarter of the 19th century. Its ornament is markedly asymmetrical, and principally floral, particular use being made of the lily. It is strongly curvilinear, and there is hardly a straight line to be seen. It often derives its effect from an incongruous juxtaposition of decorative motifs. In furniture, for instance, the asymmetry of Rococo is to be found in its ornament, but in Art Nouveau the whole piece of furniture in some cases is asymmetrical, one side being higher than the other. Although the style created much interest at the Paris Exhibition of 1900, it never became very widely established but was one of several leavening agents in the sphere of design. Nonetheless, its influence extended beyond World War I into the 1920s, when the Art Deco style from Paris became current (see below). Its influence can also be found in such relatively modern designs as the Barcelona chair of Mies van der Rohe of 1929.

Reaction against overcrowded, fussy interiors gathered strength. Plain interior walls in white or very light colours, natural woods, and simple doors and fireplaces were among the changes introduced by the more advanced designers in an attempt to create an original style suited to the changed circumstances of life in the first part of the 20th century.

Late 18th to early 20th centuries in the U.S. *Classic movement after the Revolution, 1785–1835.* Even after the American Revolution, English decorative influence predominated in the United States, in spite of greatly increased contacts with French thought and ideas. Although many leaders like Thomas Jefferson wished to see a complete break with English traditions, the Georgian forms of colonial days persisted in common usage till 1800 or after. By 1785, however, the reaction in Europe against the rather heavy classic style called free Palladianism and its Rococo and Baroque elaborations began to affect design in the United States.

Jefferson, largely under French influence, became the leader of one aspect of the new movement in the South that combined practical planning with a literal classicism based on the direct study of ancient monuments. While Jefferson's interest in strict classic form was felt particularly in architecture, the decorative phase of the movement, both North and South, was dominated by the freer and more personal interpretation of classic motifs based on the work of the Adam brothers in England, before and during the American Revolution. This was the principal influence in the designs of the Boston architect Charles Bulfinch and his followers and was popularized about 1800 in the builders' pattern books of William Pain and Asher Benjamin.

The houses of Boston, Salem, and Portsmouth that were built around 1800–10 by or under the influence of Bulfinch and Samuel McIntire, an architect of Salem, are the best examples of the changes wrought by the fine scale and delicate precision of their Adam-inspired designs, producing what has become known as the early Federal style. In the houses of the time, the circle, the ellipse, and the octagon were introduced as occasional variations in the plan, and the flying or freestanding staircase became a characteristic of the entrance hall (Figure 43). Federal style

In interior decoration, wood panelling was practically abandoned or was restricted to the area below the chair rail—*i.e.*, the wall molding at the height of the chair back. Decorative emphasis was concentrated on the mantel and overmantel, the doors and window frames, and the cornice, all usually of wood and enriched with delicate repeat ornament (either carved or applied). Rich colour in draperies and upholstery was set off by wall surfaces and decoration in light tones, grayed tints, or white. Block-printed wallpapers with classical motifs were frequently used, as were stencilled decorations in the simpler homes.

In general, geometric forms and the urn, swag, patera, and wreath were employed. The taste for lightness and attenuation verging on dryness was reflected in the furniture. The designs of the English furniture manufacturers George Hepplewhite and Thomas Sheraton, influenced by Louis XVI and Directoire forms, found American versions around the turn of the century in the work of Samuel McIntire of Salem, John Seymour of Boston, Duncan Phyfe of New York, Henry Connelly of Philadelphia, and the cabinet shops of Baltimore and Charleston. At first, light woods and finishes and decorative inlays were preferred, but by 1820 French Empire influence substituted dark reddish mahogany, carved and gilded ornament, and heavy, often ill-proportioned forms considered more in keeping with classic taste.

After 1820 the early Federal style waned, and Jeffersonian classicism was modified by the introduction of Greek and even Egyptian detail, constituting the so-called Greek Greek Revival style

Revival. Accompanied by furnishings and draperies in the heavier Sheraton-Empire taste, the classic pattern established in the 1820s became the basic style in building and decorative design. Stimulated by the Greek struggle for national independence, it lasted until about 1850 and constituted for the time a national style without parallel in Europe. In its later decorative aspect, however, the Greek Revival became a fashion rather than a style. As such it marks not only the end of the 18th-century Neoclassicism but the beginning of the Romantic movement.

The Romantic movement and the battle of the styles, 1835–1925. The ordered symbolism of the Roman classic style had been envisaged by Jefferson as a proper expression of the American national ideal; but by 1835 its restraints had grown tedious. Social and economic changes already initiated by the Industrial Revolution encouraged reaction. This found more or less romantic and emotional expression in a series of style revivals ill-adapted to actual conditions.

The Greek Revival was diluted almost immediately by the antiquarian Romanticism of the "Gothic," "Tuscan," and "country cottage" fashions. These offered opportunity to the undercurrent of practical utilitarianism, repressed or thwarted by the classic formula, and also gave a fertile field for the novel or exotic in decorative taste fostered by a wealth-induced appetite for comfort and display (see Figure 2, left and Figure 9). By the middle of the century the last vestiges of order in early Victorian Romanticism had disappeared under a plethora of decorative motifs and objects easily and inexpensively produced by machine (Figure 44). Colour became confusedly drab or brilliant and generally out of character, as a result of the introduction of uncontrolled chemical dyes and the magic of the Jacquard loom, which permitted the weaving of intricate patterns. Increased travel and ease of communications made American styles hardly distinguishable from those of Europe.

Machine-produced decoration

This decorative salad of classic and medieval motifs was supplanted by the revival of the 18th-century forms which temporarily triumphed in the "second Rococo" of the 1850s, when rosewood and walnut took the place of mahogany. This was succeeded by fashions based on the 17th century and the later Renaissance, until the Philadelphia Centennial Exhibition of 1876 brought to America the "craft" medievalism and a new series of more literal

style revivals including that of colonial times. These in turn absorbed the exotic Eastern influence of the Aesthetic movement of the later 19th century.

In the first quarter of the 20th century this confusion culminated in antiquarianism for the wealthy and, for most people, period reproductions provided by the wholesale decorator and manufacturer. These 90 years of enormous technical and financial development are too confused and complex for further analysis here. Almost from the beginning, however, a body of criticism and rational experiment was developing both in Europe and America that was to find effective expression in the early 1920s amid the social and economic upheavals following World War I.

20th century. The principle behind a great deal of 20th century interior decoration was first expounded in Chicago in 1896 in a magazine entitled the *House Beautiful.* This journal opposed both the perpetuation of vulgar display

and the excess of ornament that had characterized most of the 19th century. Other American magazines like *The Ladies Home Journal* soon followed *House Beautiful*'s lead and published articles on modern decorating (Figure 45). In Europe a group of architects and designers whose thesis was that "form follows function" started the Bauhaus, a school of design founded in 1919 at Weimar, Germany. With such pioneers of modern art and design as Walter Gropius, Paul Klee, László Moholy-Nagy, and others on its staff, it sought to teach the combining of art with craft, and to combat the dehumanizing effect of the machine.

Influence of the Bauhaus

The struggle between the desire to cling to tradition and the necessity of accepting a society based on mechanized industry came into the open between World War I and World War II. The aim of the Bauhaus group was to adapt industrial techniques to meet the needs of a society impoverished spiritually and materially by war. Their work was the culmination of the numerous reform movements of the late 19th and early 20th centuries; cathartic and analytical in its methods, on one hand it shocked the conservative into immoderate fury and on the other converted its radical adherents into equally uncompromising iconoclasts. Many of the "functionalist" ideas they employed were inspired by the subtle simplicities of the Japanese tradition and by the innovations and writings of the Chicago architect Louis H. Sullivan. Functionalism demanded a complete break with the ornamental motifs of the past and a quickened response to form, proportion, line, and texture. It also aimed at a scientific study of human behaviour, correlating psychological responses to physical stimuli of all kinds. The acceptance of its thesis ran parallel to the growth of interest in abstract art, and, although the uncompromising application of so intellectual a program proved immediately impracticable, its bold challenge to convention resulted in notable changes in interior design.

The style that emerged from the Bauhaus, called the International Style, was felt by many to be lacking in human warmth. Its boxlike forms, its hard and glassy surfaces, its use of metal tubing and plywood, and its lack of colour and of ornament were received with mixed feelings. The French architect Le Corbusier adhered to similar principles. His famous dictum that the house is a machine brought the retort that most people do not like living in machines. Functionalist thinking, however, led to an increasing use of the materials the machine is capable of producing, such as plastics, synthetic fibres, acrylic paints, and so forth, but these materials were still too often used to simulate other materials.

German Functionalism was slow to establish itself in Europe and hardly affected American design until its leaders found refuge in the United States from Nazi oppression. There the movement was brought to public attention in the mid-1930s by the need for new stimuli in the trough of economic depression, by the educational campaigns of the Museum of Modern Art in New York City, and by the reestablishment of the Bauhaus teachings in the Institute of Design of the Armour Institute (now part of the Illinois Institute of Technology) in Chicago.

Art Deco style

In the decade following the Exposition Internationale des Arts Décoratifs et Industriels Modernes, held at Paris in 1925, progressive Western design was influenced principally by the less radical productions of the French luxury crafts, based on a modified Art Nouveau, and by the Swedish success in combining and developing craft traditions in cooperation with industry. These influences, which developed the Art Deco style, were, however, confined to relatively small and semiprofessional coteries, while the market as a whole continued to concentrate on traditional forms, producing and adapting them at various levels of quality and taste (Figure 46). By 1935 the Functionalist movement, led by the disciples of the Bauhaus program, had gained a substantial following among the younger architects and designers. During World War II, development virtually ceased in most European countries, and subsequently attention turned again to the Scandinavian countries, particularly Sweden, where strict consideration of function led to simple furnishing schemes which relied on natural wood grains, clear colouring, and texture for their effect. Pattern was subdued and, where used, uncomplicated in outline.

Meanwhile, in the United States, during and after World War II, the Functionalists, still with the help of the museums and the more progressive schools and periodicals, had gained the interest of a considerable proportion of both the wealthier members of society and the manufacturers who catered to them.

Effects of the Functionalist movement

The most obvious changes resulting from the Functionalist movement were mechanization, redistribution of interior space, and elimination of formal barriers between indoors and outdoors. These developments, most prevalent in the United States but disseminated throughout much of the world, were accompanied by radical changes in decoration and the design and use of furniture and fittings. Equipment for heating and lighting, sanitation, and food preparation, all derived from inventions of the 19th century, were brought to a high degree of mechanized efficiency, taking full advantage of advanced production methods. Since convenience and economy became principal considerations, utility units were fitted into living space instead of being hidden in otherwise unused areas, as in the traditional room arrangement. By insisting on simplicity of form, colour, and texture, they were made to obtrude as little as possible. In particular, the appearance of the kitchen was studied carefully, especially in smaller houses.

Under the influence of electric power, liquid fuels, flexible controls of temperature, ventilation, and lighting, and countless labour-saving devices, the mid-20th-century house began to fulfill Le Corbusier's dream of an efficient "machine for living."

Reconsideration and correlation of the space needed in living areas broke down traditional room divisions. The new interior, with its invitation to movement, both actual and implied, was in harmony with the times. Decoration became concerned with function (see Figure 2, right), and, because a living area served more than one purpose, it

was frequently irregular in plan and impossible to treat as a unit in the traditional formal manner. Changes of colour, texture, and materials consequently became the chief resources of decorative design, taking the place of ornament (Figure 47). Earlier attempts at the functional mode suffered from too much anxiety over simplicity and unity and thus became monotonous and cold.

Photo R Guillemot—TOP

Figure 47: Dining room and living area designed by Claude Lombardo for his apartment outside Brussels, 1969. Supple, rounded forms made of cement reinforced with glass fibre are used to create a free-moving, open-plan interior.

The demands of space made it necessary to keep movable pieces of furniture to a minimum and encouraged the use of built-in units. An earlier overemphasis on straight lines and angles was countered by greater use of curved and molded forms in furniture design. As the average house became smaller and more efficient in its use of enclosed space and as the desire for outdoor living grew, there was a tendency to replace at least one of the enclosing walls of both livingroom and bedroom with glass. With a well-arranged plan, this gave each room an everchanging mural and better light, and it also extended the apparent size of the interior. The illusion of bringing the outside indoors gave a feeling of freedom, but it also created practical and psychological problems (see Figure 7).

Despite the reaction that developed against it, the functional modern movement had served an important purpose. Although it produced no recognizable themes of ornament, it did eliminate the *horror vacui* that afflicted the Victorians and Elizabethans alike. It cleared the way for a fresh look at the art of interior decoration as a whole, and for the fresh inspiration that came in the 1950s from Scandinavia and Denmark, which retained the human qualities that much of the work of the Bauhaus was felt to lack. At the same time there was a revival of interest in true Japanese art in interior decoration, which has a certain affinity with Scandinavian. In the 1960s patterns began to return—abstract patterns such as those to be found in Op art. Elegant materials, easily washable, became available for upholstery, and easy cleaning made it practical for them to be produced in pastel shades and light colours.

That large numbers of people had found it difficult to live with modern austerity became apparent with the immense growth after World War II of the trade in old furnishings of all kinds, with ever-increasing prices. A parallel vogue resulted in an increase in the manufacture of reproductions of all kinds, especially furniture, made partly by machine and partly by hand, leading to the revival of some of the old handcrafts.

INTERIOR DESIGN IN THE EAST

East Asian motifs of decoration bear no relationship to those of the West, although many of them are familiar from *objets d'art* and decoration exported during the last five centuries. No such conflict of styles as those to be observed in the West has existed.

Eastern motifs

The motifs of Eastern art are many and varied, such as the dragon (a ubiquitous and beneficent creature), the so-called phoenix (actually the Chinese long-tailed pheasant), and creatures of all kinds, actual and legendary. Flowers and foliage are part of an elaborate flower-symbolism, and there are many abstract motifs, all of which are part of a complex and rich symbolism, which can usually be interpreted if the key is known. The Chinese language contains many identical words, which have completely different meanings that are identified in speech by intonation; the word *fu*, for example, can mean either a bat or happiness. Therefore, a decoration of bats symbolizes happiness. This is not true in the Japanese language, but the Japanese have taken over many Chinese motifs, such as the bat (*kōmori*). The purpose for which a Chinese object decorated with a dragon was originally intended may often be deduced from the number of claws to the foot—five for the Emperor, four for princes of the blood, and three for officials. The pine, willow, and bamboo in conjunction are termed the "three friends," and represent Buddha, Confucius, and Lao-tzu.

Scrolls of painting or calligraphy are characteristic of interior design in the East. They are changed from time to time to give freshness to the decorative scheme and also to emphasize their quality. Similarly, a vase with a single branch of peach blossom or other flowers may be set out with care. Cabinets and storage chests are of great importance and are often made of camphor wood. An important feature in the houses of north China and Korea is the *k'ang*, or heated brick platform, on which the family sleeps or sits in the cold northern winter.

China. Possessing the oldest Eastern civilization, China has powerfully influenced the others. Forms and motifs of decoration, which began as early as the Shang dynasty (18th to 12th century BC), or even before in the legendary Hsia dynasty, persist throughout Chinese history. Early forms of bronze altar vessels, for example, are found in porcelain in the 18th and 19th centuries, slightly altered in profile but still recognizable.

Materials are very different from those of the West. The Chinese have always been masters of the ceramic art, and their skill spread northward to Korea, northeastward to Japan, and south to the countries of Southeast Asia. Nearly all the more important techniques—majolica excepted—came from China. The T'ang dynasty (618–907) was renowned for fine earthenwares; the Sung dynasty (960–1279) for superb stonewares; and from the Yüan dynasty (1206–1368) onward the Chinese have led the world in the manufacture of porcelain, the secret of which reached Europe only after the porcelain had been imported for several centuries. Bronze was employed for vessels rather than figure sculpture. Originally purely religious in connotation, bronze vessels were given as gifts of emperors to their favoured subjects by the Chou dynasty (1111–255 BC), and from that time on were commonly employed for secular purposes. During the T'ang dynasty, handsome mirrors as well as such useful and decorative things as toilet-boxes were commonly made.

Chinese textiles

China was known for its silk in the West in ancient Roman times. Fragments of silk were found in Chinese Turkistan dating to the 1st century BC with motifs of design strongly resembling those of the 20th century. The Chinese have always been noted for superb silk embroideries, highly detailed in a manner requiring a multitude of tiny stitches. Painted silks have been produced in large quantities. Velvet weaving, usually in long strips as chair

covers, was an art probably learned from the West, but the art of tapestry (*k'o-ssu*), may go back as far as the Han dynasty (206 BC–AD 220). Carpet-knotting of the highest quality, no doubt learned from Persia, cannot be proved to date before the 17th century, but it may have started at a much earlier date. Rare carpets are knotted with silk and gold, but those with a woollen pile are of fine quality. Pillar-carpets, woven to encircle pillars, are a distinctively Chinese type. Motifs of decoration are those common to other materials.

Jade (nephrite and jadeite) is carved in China into objects with many different purposes. In early times, like bronze, it was mainly used for religious purposes, but it later came to be employed for a variety of secular objects, principally those intended to furnish the scholar's table, such as brush-pots, ink-slabs, water-droppers, table-screens, and paper-weights. In the 18th century especially, bowls and covers, handsomely carved and pierced with a variety of motifs and patterns, were made for interior decoration as incense burners.

Lacquer, the solidified sap of a tree (*Rhus vernicifera*), has been widely employed for a variety of decorative purposes on a foundation of wood or, less often, hempen fabric. Lacquer is employed as a form of paint, or applied in thick layers that can be carved with knives. It is also used to decorate structural timbers in the interior. The finest lacquer came from Japan in the 17th and 18th centuries.

Enamelling on metal is an art that the Chinese learned from Europe, but, in the 18th century especially, some very large bronze vessels in a variety of ornamental forms were covered with enamel utilizing the cloisonné technique. Painted enamels came from Canton in the 18th century, and resemble in style contemporary porcelain enamelling from the same place.

Paintings are usually on silk, and most are in the form of scrolls to be hung on the wall. A long and narrow form is customary. The best of Chinese painting is superb in quality, but criteria of judgment are very different from those applicable to Western art. Style is to a considerable extent affected by calligraphy, and the quality and type of brushstroke plays an essential part. Subjects are usually the poetic delineation of landscape, floral and foliate sprays, and, less often, pavilions. Chinese painting is often pervaded by a subtle and gentle humour hardly seen in Western art. Calligraphy plays an important part in the art of the East; scrolls decorated with an admired calligraphy are hung on walls. Calligraphy often plays a part in the decoration of bronzes and porcelain, and inscriptions on paintings are not uncommon.

The Chinese house

The East Asian house is usually constructed of wood and tiles. The ridge-tile in China, made of glazed stoneware, is often very handsome. Architecture has never been the principal medium for the expression of the Chinese artistic impulse; conservatism, perhaps rooted in ancestor worship, has been paramount and stylistic innovation practically unknown. The basic structure of the Chinese house has remained almost unchanged at least from the Shang dynasty (18th to 12th century BC). In all types of buildings the roof is the most important feature, and by the T'ang dynasty (AD 618–907) the characteristic upturned eaves and heavy glazed and coloured tile covering had developed. The roof is chiefly supported by timber posts on stone or bronze bases, and the walls of the building serve merely as screens in brick or timber. Floors are often of beaten earth packed tightly into a timber border. Usually, a family house was composed of a series of buildings or pavilions enclosing a garden courtyard and surrounded by a wall. The courtyard played an immensely important part, because of the ever-present ideal that man should live in harmony with nature: a small pool with a lotus plant, a tree, and large rocks symbolized the whole natural landscape, and it was on these features that most care was lavished.

The supporting pillars and brackets of important buildings were carved and painted, many of the designs being similar to those made familiar by Chinese pottery and porcelain. The yellow dragon symbolizes the power of the spirit, the tiger the forces of animal life. Windows were latticed with strips of wood in varying patterns over which translucent white paper was stretched. In addition to the lattice-work patterns, the windows themselves took on great variety of outline, for instance that of a diamond, fan, leaf, or flower. Doorways, too, were fancifully shaped in the form of the moon, lotus petal, pear, or vase, for structural support was not required from the light panel-type walls. Some walls may have been removable altogether, as they were subsequently in the Japanese house; others were of painted wood, hung with tapestries or paintings on silk and other materials.

A description of a Ming (1368–1644) home of the leisured class mentions ceilings with cloisons (compartments) in yellow reed work, papered walls and pillars, black polished flagstones, and silk hangings. Richly coloured rugs, chair covers, and cushions contrasted with dark furniture, which

By courtesy of the Philadelphia Museum of Art, given by Wright S Ludington (in memory of his father)

Figure 48: Chinese scholar's study, Peking, late 18th or early 19th century. In the Philadelphia Museum of Art.

was arranged according to the strict ideas of asymmetrical balance.

Chinese furniture

Little is known of early Chinese furniture, apart from what may be gathered from paintings and similar sources. Low stools and tables were early in use, and chairs, dressing tables, altar tables, and canopied beds were common by the Western (early) Han dynasty (206 BC–AD 25). Designs and materials underwent very little change in the intervening years. Rosewood has always been widely employed, and in the palaces elaborate pieces were encrusted with gold and silver, jade, ivory, and mother-of-pearl. The Chinese interior was more extensively furnished with chairs, tables, couches, beds, and cabinets of cupboards and drawers than was the custom elsewhere in the East (Figure 48). As in Europe, the chair with arms was thought to be a seat of honour. The woods employed are native to the country and were hardly ever exported to the West, though Chinese rosewood is fairly well known in the West because most exported furniture was in this wood. Carved lacquer furniture, like the throne of Ch'ien Lung in the Victoria and Albert Museum, London, was reserved for the emperor and high officials, and the massive incised lacquer screens, known in the West as Coromandel screens, were occasionally exported. Furniture of bamboo, principally intended for garden use, has hardly survived, but barrel-shaped seats of porcelain for the same purpose are not uncommon. Carved decoration on furniture is nearly always extremely simple in design and limited to some form of interlacing fret.

Japan. Interior decoration in Japan was much influenced by Chinese ideas, especially between the 8th and 12th centuries, but it developed along lighter, more austere and elegant lines. It has altered little since medieval days.

Comparison of Chinese and Japanese design

The most important differences in modern design are that the matting has been extended to cover the whole of the wooden floor, and sliding doors have replaced single-leaf screens or curtains. Two sides of a Japanese house frequently have no permanent walls, and interior partitions are of paper on a wood frame which admits a soft, diffused light. These partitions are usually moveable, allowing the interior to be rearranged (Figure 49).

The Japanese interior is a carefully thought-out arrangement. Wall-decoration hardly exists, and the walls provide a neutral background for the rest. Since the Japanese invariably cover their floors with rice-straw mats and sit on them instead of on chairs, tables are low, and are also used as an arm-rest. Tiers of shelves are common, usually covered with lacquer, and painted decoratively. They occur in a variety of forms, and the asymmetrical quality of Japanese art may be seen in these pieces of furniture, the number and position of the shelves differing on either side, and set at different heights.

In contrast to Western practice, the Japanese do not decorate their rooms with several works of art, but have a special place in the room, a focal point, at which one work of quality is displayed, and this is changed from time to time. Both the Chinese and the Japanese venerate the work of former times, and the Japanese possess the oldest art collection in the world, in the Shōsō-in repository at Nara, which was formed in the 9th century AD.

At that time, doors were pivoted in the Chinese manner, and instead of the sliding *shōji*, windows were made of wooden latticing that pushed outward, as may still be seen in shrines and temples. There was a curtained dais for the most important person and separate mats on the wooden floor for others. Then, as now, there was a connecting corridor outside the rooms. The Seiryo-den, or ordinary residence of the sovereign in the Kyōto Imperial Palace, belonged to this period and was reconstructed in the 19th century on the model of the original. A present-day family could live quite comfortably in its simple suite of rooms with walls and standing screens decorated with pictures in the Chinese classic manner.

Late in the 15th century the interior began to assume its present form as a result of a slow blending of the older court style with the more austere type of house favoured by the military caste, which was much influenced by Zen Buddhist architecture. Toward the end of the 16th century came the rise of the tea masters. These connoisseurs of the "way of tea," which involves the construction of the tearoom and its garden and correct deportment in them, established hereditary families and schools who remained the aesthetic advisers on most aspects of domestic architecture, interior decoration, and garden planning. They aimed to achieve beauty with frugality, asymmetry, and economy of movement, and much of the simple grace of Japanese interiors is due to them.

Influence of the tea ceremony

In a modern Japanese house built in traditional style, decoration is almost entirely structural, and the residences of all classes are equally neat and free from vulgarity. Their harmony and delicacy derive from an endless variation of detail in a setting that is completely standardized. Ordinary rooms are reckoned in terms of multiples of the floor-mat unit, six by three feet (1.8 metres by 0.9 metre); the sliding doors five feet eight inches (1.7 metres) high by three feet wide; the supporting pillars four to five inches (10 to 13 centimetres) square, set at six-foot intervals; and the ceiling boards one foot to 1.5 feet (30 to 45 centimetres) wide. All woodwork is unpainted and rarely lacquered, but there is great variety in the *fusuma*, or sliding doors, which divide the rooms and which are covered with paper of many patterns or decorated with paintings or calligraphy. Thus, the whole side of a room may present a landscape either in black and white or in

Figure 49: Japanese pleasure house: "Moonlight Revelry at the Dozō Sagami," ink, colour, and gold on paper by Kitagawa Utamaro (18th century). In the Freer Gallery of Art, Washington, D.C.

colours, often on a silver or gold background. A change of these *fusuma* will alter completely the appearance of a room, and their removal will convert two or more rooms into one. All rooms can be used as bedrooms, since the bedding is stored in spacious cupboards. The reception rooms provide more scope for decoration than the others, for one end of the room is occupied by a *toko-no-ma,* an alcove with a canopy above it supported by a pillar of fine or uncommon wood, in which is hung the picture or set of pictures that, with the flower arrangement that usually accompanies it, is the only ornament. Both are changed frequently according to the season or mood. Next to the *toko-no-ma,* there is often a built-in writing table. Beside this is usually a *chigai-dana,* an asymmetric arrangement of cupboards and shelves somewhat like a sideboard. Between the top of the *fusuma* and the ceiling is often a *ramma,* an openwork frieze carved with patterns or landscapes in wood or bamboo. A framed tablet with a poem or painting on it sometimes may be placed there. Other walls are of plain plaster in subdued shades, mostly of gray or brown. The ceilings are usually of thin boards, slightly overlapping, upheld by bars about an inch (three centimetres) square, the whole suspended from the roof or floor beams. In large apartments, as in shrines and temples, the coved and coffered "Chinese ceiling," with lacquered woodwork and pictures and patterns in the coffers, is sometimes found. Fancy varieties made of bamboo and reeds and plaited wood are not uncommon. Bamboo has many uses in the Japanese house as pillars and window bars and ceiling material, when split and flattened, it may take the place of boards. Windows are of many shapes—round, square, bell-shaped, jar-shaped, gourd-shaped, diamond-shaped, fan-shaped, and purely asymmetric—and make centres of interest in a blank wall.

Types of ceilings

The furniture in a traditional Japanese house is sparse, perhaps consisting of a cabinet of blackwood or lacquer, a low writing table or a screen, either twofold or sixfold (the latter generally in pairs), decorated with landscapes on a gold or silver background and mounted in brocade. A single-leaf screen sometimes stands in the entrance hall. Among the well-to-do, other valuables such as scroll pictures, charcoal braziers, articles of pottery, spare *fusuma,* books, and curios are kept in a detached fireproof storehouse and produced only occasionally to ensure a constant variety in the rooms. It is a principle that rooms that are only occasionally occupied may be more showy and fanciful than ordinary living rooms, and these are most often met with in hotels and restaurants and other places of entertainment. Just as much care is taken with the interiors of the bathroom as with the other rooms, and the doors and windows and walls of these are usually of excellent workmanship.

India. Words of Indian origin such as calico, chintz, and palampore indicate the importance of Indian textiles in the history of western interior design. Yet the Indians themselves have never been very conscious of this role, their own domestic interiors being of the utmost simplicity, with hardly more than a carpet or prayer mat to offset stone floors and plain white walls (Figure 50). The impermanence of the materials used for the majority of dwellings may have been a contributory factor. In more palatial buildings, however, and commonly in both Hindu and Buddhist temples, walls were painted, a practice that, according to literary references, may go back to the Maurya period (321–185 BC). Paintings that survive in cave temples of the Gupta period (AD 320–600) usually depict groups of active mythical or human figures and are characterized by their sinuous lines. A late example occurs in the unfinished early 17th-century murals of the Mattāncheri palace, Cochin, Madras. Inlay of semiprecious stones, carved and bracketed pillars and capitals, and openwork marble panels also adorned the palaces of local rulers.

FURNITURE AND ACCESSORY FURNISHINGS

The word furniture comes from the French *fourniture,* which means equipment. In most other European languages, however, the corresponding word (German *Möbel;* French *meuble;* Spanish *mueble;* Italian *mobile*) is derived from the Latin adjective *mobilis,* meaning movable. The continental terms describe the intrinsic character of furniture better than the English word. To be furniture, it must be movable.

In general, furniture produced in the last 5,000 years has not undergone innovative development in any profound sense. An Egyptian folding stool dating from about 1500 BC fulfills the same functional requirements and possesses the same basic features as a modern one. Only in the mid-20th century, with entirely new, synthetic materials such as plastic and completely new fabrication techniques such as casting have there been signs of a radical revision of the concept of furniture. Since furniture presupposes some degree of residential permanency, it is understandable that no independent furniture types seem to have been developed among the Africans, the Melanesians, the Eskimos in Greenland, the American Indians, or the Mongolian nomads in Asia.

This section deals with the materials, processes and techniques, ornamentation, kinds of furniture, and, finally, with the history of furniture.

General considerations

MATERIALS

Wood. Wood is the most used and possibly the best suited material for making furniture. Although there are over a hundred different kinds that can be used for furniture, some woods have natural properties that make them superior to the others.

A relatively cheap material, wood lends itself to various kinds of treatment; for example, it can be stained, painted,

Advantages of wood

gilded, and glued. It can be shaped by means of hand- or power-operated cutting and drilling tools. Heated, it can be bent to a certain extent into a predetermined shape and thereafter will retain the shape. The annual rings in wood create a structure with varying character, which in itself provides a natural ornamental surface, in which patterns can be formed by means of precalculated juxtapositions. Colours range from white, yellow, green, red, brown, grey to black through countless intermediary tones. By juxtaposing wood of different colours, extremely rich effects have been achieved, especially in the 17th and 18th centuries. Wood, if stored under favourable conditions, is durable, and pieces of furniture from the oldest civilizations—Egypt, for example—are still extant. Lastly, most wood has an aromatic scent.

Developments in the sphere of craftsmanship and mechanical techniques, during the past two hundred years or so, have made furniture production both cheaper and quicker. Using timber as a basis and applying techniques such as shredding, heating and glueing, it has been possible to evolve new materials. To an increasing extent, cabinetmakers and furniture factories are using semi-manufactured wood such as veneer, carcass wood, plywood, laminated board, and hardboard (fibreboard).

Use of veneer

Veneer is a very thin layer of particularly fine wood that has been glued on to inferior wood in order to produce a smooth and beautiful surface. It would hardly be possible to achieve such a surface by using solid wood, partly because of the expense, partly because of its brittleness, and partly because the grain can never be shown off to its best advantage when the timber is cut into solid boards.

The practice of veneering furniture has been known since the time of pharaonic Egypt, but it was not fully exploited until the beginning of the 18th century. During the Rococo period, especially, great virtuosity was displayed by the craftsman in the veneering of curving, concave, and convex surfaces; for instance, as found on chests of drawers.

Veneer is made by sawing, machine-cutting, and peeling. Saw-cut veneer is best, but because of the relatively large loss of wood in the form of sawdust, it is also the most expensive. Therefore, furniture veneer, as a rule, is machine-cut.

Veneering is done on carcass wood, either in the form of a solid surface or a surface composed of several layers glued together. Old furniture is nearly always veneered on solid wood of an inferior quality to the veneer, such as beech, oak, or deal. High-quality English mahogany furniture made in the 18th century, however, was veneered with mahogany on mahogany. In the 20th century, machine-made laminated board of various thicknesses is generally used. The advantage of ready-made laminated board is that it does not shrink. Wood expands and contracts in various ways, and its strength can vary axially, radially, or tangentially; by blocking the wood—*i.e.*, glueing pieces of wood together in different directions—such differences are eliminated and equal strength is obtained both longitudinally and laterally. The characteristic feature of laminated board is that the veneer on both sides encloses a wooden board composed of narrow strips of wood glued together on edge. The board is therefore thick enough to be suitable for table tops or doors.

If laminated board consists only of single sheets of veneer glued together, it is known as plywood. Plywood is widely used in the manufacture of furniture, particularly as backing for chests and other storage pieces, for the bottoms of drawers, and for shelves.

Metal. Metals have been used since antiquity for making furniture or ornaments for furniture. Splendid Egyptian pieces, such as the thrones and stool that were found in the tomb of the youthful Tutankhamen (14th century BC), were rich in gold mounts (decorative details). In ancient Greece, bronze, iron, and silver were used for making furniture. Finds that were buried in the ashes of Pompeii and Herculaneum in Italy included tables with folding underframes and beds made partly or entirely of metal.

Throughout the Middle Ages the metal chair—for example, the 7th-century throne belonging to Dagobert I, king of the Franks—was used for special ceremonies.

Various examples of silver furniture have been preserved; not solid metal, they consist of embossed (decorated with relief) or chased (hammered) plates of silver fastened to a wooden core. Silver furniture was made for palaces in the days when monarchs amassed enormous wealth. In times of war, the silver mountings were melted down and turned into silver coins; it was thus that all the silver furniture disappeared from the royal palaces of France.

Popularity of iron furniture

During the 18th and 19th centuries, iron furniture became a typical industrial product. Iron beds in particular became popular. Because they could be easily folded up, they were much in demand as camp beds; one used by Napoleon at St. Helena is a famous example. As ordinary beds in private homes or hotels, they could be decorated with brass ornaments such as big knobs screwed onto their posts. Iron has also been used for chairs; for instance, rocking chairs or, perhaps more frequently, garden chairs that can stand out in the rain, protected only by a coat of paint.

The possibilities of steel for furniture were explored in Germany during the 1920s, notably by architects associated with the Bauhaus, where architects, designers, and artists experimented with modern materials. Experiments were made with steel springs and chromiumplated steel tubing. The genre was soon imitated, and tubular steel furniture became a symbol of functionalism. Since then, thinner tubing and plaited wire, with a resiliency similar to that found in wickerwork chairs have been used. Because of its lightness, aluminum became a furniture material.

Metal, however, is still employed primarily for locks, mounts, and hinges used on furniture or for purely ornamental purposes. In the Middle Ages, simply constructed chests demanded extensive use of iron bands to provide extra strength, and the ends of these bands were cut to form decorative shapes. Cabinets of the Renaissance and Baroque periods were decorated with mounts of pewter or bronze. Inlaid objects, decorated with material such as wood or ivory, set into the surface of the veneer furniture made at royal furniture workshops in France, especially so-called boulle furniture, were marked by an elaborate style of marquetry (patterns formed by the insertion of pieces of wood, shell, ivory, or metal into a wood veneer); they were influenced by Oriental traditions, in which blue-

tempered steel, brass, and copper were customarily used.

In the 17th and 18th centuries, especially in England and the American colonies, a refined style for furniture mounts, keyhole escutcheons (an ornamental shield around a keyhole), hinges, and the like, all based largely on Chinese models, was developed. The design of these mounts was dictated by a clear functional purpose, in contrast to contemporary French Rococo mounts, the majority of which were ornamental, often at the expense of utility. French bronze founders displayed great skill in making purely decorative mounts for the bodies of chests of drawers and protective mounts for corners and legs. No essentially new, independent forms of furniture mounts seem to have been developed since the 18th century.

Other materials. Among other secondary materials in furniture making, glass has been used in the form of mirrorglass or as a purely decorative, illusionistic element in cabinets and writing desks. Italian craftsmen have made glass furniture; that is, wooden furniture covered with silvered glass in various colours. Ivory and other forms of bone were used as inlay material in Egyptian furniture. During the 17th and 18th centuries, ivory was widely used for inlay work in cupboard doors and table tops.

Tortoiseshell was also used, as a costly inlay on a silvered ground, in furniture made during the Renaissance and Baroque periods. Mother-of-pearl has been used, particularly as inlay material and for keyhole escutcheons. Marble and, to a certain extent, plaster of paris have been used, especially in the 18th century, for the tops of chests of drawers and console tables, and in the 19th century for the tops of washstands and dressing tables.

Papier-mâché and plastics

In Victorian England, papier-mâché (a molding material made of paper pulped with glue and other additives) was used to make such items of furniture as fire screens, small tables and chairs, and clock cases. Finally, since World War II, various plastic materials have been used quite extensively in the construction of chairs with seats and backs molded in one piece and provided with a metal base.

STYLISTIC AND DECORATIVE PROCESSES AND TECHNIQUES

Constructional style and stylization. In general, furniture can be designed in two styles, one of which is constructional in that the appearance of the piece reflects the way it is put together, and the other of which is stylized in that the appearance of the piece conceals the way it is put together, the principle being to make the joints flush with adjoining members so as to give the impression that the object is made in one piece.

Examples of furniture made in a purely constructive style are forms employing wickerwork or bamboo, in which even the greatest display of imaginativeness in design and pattern serves to make the construction stronger and more resilient.

Constructional details and joints are not normally visible and are, therefore, seldom of aesthetic importance to the external appearance, but joints can be emphasized artistically. The Greek form of chair known as the klismos (Figure 52) demonstrates its joints boldly in the form of solid junctions holding the legs, seat, and stiles together. The curvature of the legs and of the backrest suggests elasticity. Extremely delicate joinery with invisible joints can be deliberately indicated by means of inlay work, examples of which can be seen in ancient Egyptian furniture.

Stick-back and tubular steel chairs are also examples of constructional styles. The stick-back chair consists of a solid seat into which the legs, back staves, and possibly the armrests are directly mortised (joined by a tenon or projecting part of one piece of wood and mortise or groove in the other piece). Furniture of bent steel tubing, particularly tables, chairs, and stools, was manufactured in Germany in the 1920s (Figure 58). In this fashion a new constructional style arose, for the steel tube, which makes smaller dimensions possible, was so strong that it opened up the possibility of completely new designs. Bent steel tubes form a resilient structure.

Stylization

In contrast to the constructional style is stylization, in which there is no internal conformity between the motifs and the strength of the joints. There have been any number of examples of stylization throughout the history of furniture. In both Egyptian and Chinese furniture the joints might be deliberately concealed by painting or lacquer. Chinese furniture can also appear stylized in the sense that it gives an impression of having been put together in a more constructive manner than is actually the case. (In other words, stylization attempts to make joints flush with adjoining members so as to give the impression of an uninterrupted, harmonious, or sensitive contour. When two pieces of wood are joined together with a modern, strong glue, the resulting joint will be so rigid that, in the event of a severe shock to the piece, the wood itself will be more likely to break than will the actual joint.)

A good example of stylization is to be found in French furniture made around the middle of the 18th century. In French Rococo commodes, only the back is straight. The serpentine front and sides meet in sharp corners, at which the joints are covered by brass mounts. The number and position of the drawers is concealed by an over-all pattern of veneer and bronze ornament that disregards the edges of the drawers. (In a number of cases the bronze mounts on the front consist of fanciful handles and keyhole escutcheons, but are never emphasized the way they are in corresponding English commodes, even in the case of false drawer fronts or drawers provided with moulding that serves to protect the veneer.) The fully developed French Rococo chair (Figure 53) with armrests has no visible joints. The back, arms, and frame form a continuous whole; the difference between supported and supporting members is concealed. There are no stretchers (horizontal rods) between the legs to strengthen the construction, which is solid enough by reason of the thick dimensions of the members that meet in the seat frame. To counteract the impression of heaviness in these essentially thick dimensions, the wood is molded to give a sensation of lightness without in any way weakening the construction. A chair of this type when painted or gilded looks as if it had been made in one piece, which is precisely the intention.

Decorative processes and techniques. Whether constructional principles are exploited as a motif or elegance of overall shape is stressed through stylization, every piece of furniture can be embellished in one way or another. A piece of furniture may be embellished by effects produced

Figure 53: French Rococo chairs by Louis Delanois (1731–92). In the Bibliothèque de l'Arsenal, Paris.

in the structural wood itself or in another kind of wood added to the first; that is, by carving and turning or by inlay work. Alternatively, the piece can be decorated by the addition of materials other than wood, such as bronze, ivory, or marble. Finally, in the case of furniture meant for sitting or lying on, there is the possibility of textile enrichment in such forms as upholstery, loose covers, and cushions.

Carving. There are examples of furniture carving in Egypt at the time of the pyramids: animal legs of cedarwood on biers, beds, and chairs; and ducks' heads terminating the legs of folding stools. A more constructionally determined type of carving resulted in the creation of elegant headrests that took the place of pillows in a hot climate.

Whereas carving does not appear to have played a significant part in Greek and Roman furniture, it was a dominant feature of European furniture of the Middle Ages. The fronts of chests bear Gothic perpendicular tracery (decorative interlacing of lines) in imitation of the decorative stonework found in ecclesiastical architecture.

Islāmic wood carving

Another source of inspiration for carved ornaments in bourgeois furniture was the ecclesiastical wood carving found in choir stalls and altarpieces. The art of the woodcarver also flourished in Islām during the Middle Ages, especially in kiosks (open pavilions), oriel (large bay windows projecting from the wall and supported by brackets) windows, and Qurān lecterns. The most original and remarkable form of medieval carved ornamentation was the linenfold, which resembled folded sheets of linen laid on the surface of the wood. Although the motif was widely known, its origins are obscure.

During the Renaissance, wood-carvers changed motifs: new ornamental riches, partly inspired by the forms of classical antiquity, began to adorn cupboards and chests. Acanthus leaf designs, strapwork (narrow bands folded, crossed, and sometimes interlaced), Moresque designs, the auricular (resembling a flowered Alpine primrose) style, bunches of fruit, and scrollwork for over a hundred years dominated the figure-carving repertoires of European cabinetmakers.

During the 17th century the fashion for carved work at first receded but came to the fore again in the console tables (tables designed to fit against the wall), mirror frames, and high-backed chairs of Court Baroque. In striking contrast to lacquer cabinets of Japan, sumptuous, gilded carved work became popular on the stands invariably made for them in Europe.

In the 18th century, wood-carvers enjoyed a final splendid period of prosperity when the Rococo style of ornamentation called for the plastic effects obtainable through carving. Whole panels of woodwork (Figure 51), doors, mirror frames, chairs, and settees were adorned with the finest wood carving, featuring combinations of musselshell patterns and naturalistic vines and plant tendrils. Even in English furniture of more sober design there were ample opportunities for carved work; for example, in the many chairback variations in the Chippendale manner.

American cabinetmakers were particularly skillful at carving block fronts (the sides curving forward and the middle receding) on the drawers of chests of drawers, and the English at framing tea tables with piecrust (scalloped) tops.

Turned work. Turning is a process by which parts of furniture, such as legs and posts, are shaped while turning on a lathe. Turned work is found on Greco-Roman furniture. It is not certain whether the technique was actually employed in Egyptian furniture, though some members look as though they might have been turned. It was particularly in the shaping of wooden chair legs that Greek joiners used the lathe; the same sharp edges and deep molding seem to be repeated in the legs of bronze furniture. It is possibly ancient turned work traditions upheld in Byzantium that are reflected in certain chairs of medieval form found, for example, in Norway; made of pinewood, the construction consists principally of turned staves (thin bars), some with appendant loose rings, some of them fluted (grooved). Similar turned chairs were made in Wales in the 16th century. In the 17th century, turned work was concentrated on pillars for cupboards and on ball feet, but is also seen on chair and table legs, on which rich variations involving twisted and intertwining forms occur. Turned work in ivory also flourished in the 17th century. Except for the Windsor chair, or stick-back, however, the craft of the turner played no significant role in English furniture of the 18th century; it is similarly alien to French Rococo furniture.

Inlay and marquetry. Inlaid woodwork, in which decorative material such as wood or ivory is set into the surface of the veneer, has accompanied the art of furniture making for thousands of years. Ivory inlay can be seen in Egyptian furniture, particularly in small, meticulously executed toilet caskets, but it is difficult to locate in Greek and Roman furniture, today known almost exclusively from pictorial representations.

In medieval Europe, inlay work gave way to wood carving and then experienced a rich period of development during the Renaissance in Italy. Italian intarsia (mosaic of wood) work found particular favour in panels over the backs of choir stalls and in the private studies and chapels, or oratories, of princes. An intarsia study of the Duke of Urbino, an Italian nobleman and patron of the arts, is still preserved in the palace of Urbino, and a corresponding room, originally at Gubbio, is now in the Metropolitan Museum of Art in New York. Together with illusionism, linear perspective (the technique of representing on a plane or curved surface the spatial relation of objects as they might appear to the eye), which had just been discovered, achieved triumphs in Italian intarsia work.

Italian intarsia work

Ivory was used on both Renaissance and Baroque cupboards, sparingly to begin with, lavishly later on. Inlay work was especially used in the many splendid German and French cabinets of the period. In Holland and England an extremely rich form of marquetry (patterns formed by the insertion of pieces of wood, shell, ivory, or metal into the wood veneer) was developed, incorporating floral motifs in various kinds of exotic wood on walnut. English grandfather clocks made around 1700 often had richly inlaid cases. It was in France, however, during the Rococo period especially that inlay work reached unprecedented levels of quality. The serpentine sides and fronts of commodes were veneered with costly woods whose often relatively simple grain patterns formed an effective background for richly ornamented mounts of gilded bronze.

Upholstery and covers. Upholstery and covers belong to the sphere of furniture designed for sitting or lying on. From the Orient, Europeans learned the use of wickerwork, which provided a ventilated and resilient background for loose cushions. The upholstered chair is a genuinely European phenomenon that achieved its most distinguished and logical form in England during the 18th century. Poor heating systems in houses, general prosperity, and a desire for comfort were the conditions that gave rise to a number of imaginatively varied types of upholstered armchairs in which the only wood visible is in the legs, with the back

closing right up against the sitter and side wings affording protection from possible drafts.

The upholstered chair created a new effect that depended almost entirely upon the craftsmanship of the upholsterer. The upholstered chair or sofa has remained a specialty of the Anglo-Saxon world; club life in particular contributed to its popularity and resulted in heavily stuffed forms including that of the so-called chesterfield.

By mid-20th century, new materials such as foam rubber and various types of plastic composition had inspired independent methods that dispensed entirely with traditional upholstery techniques. Upholstery was succeeded by molded plastic forms and by sacks filled with plastic balls that are able to conform to the changing positions of the body.

Imagery and ornamentation. Painted and plastic images, or ornamental decoration, on furniture are secondary processes compared with construction and design. Some of the best and most expressive furniture forms, such as the Greek klismos chair and the English Windsor chair, are quite independent of imagery or ornamentation. On the other hand, no period in the history of furniture is entirely devoid of these secondary processes.

Superfluousness of furniture decoration

All furniture decoration is normally concentrated where it will not be in the way; for example, on the legs, arms, and backs of chairs; on the ends and canopies of beds; on the legs and stretchers of tables; and on all vertical surfaces of cupboards and chests of drawers. The superfluous nature of furniture decoration is particularly pronounced in forms that express rank or prestige. The thrones of kings and bishops, the seats of guild masters, beds of state, the writing desks of chief executives, and the like have all lent themselves to imagery and ornamentation; and as the functional aspect of the piece has declined, it has seemed that the amount of ornamentation has increased. Purely functional milk stools and typewriting tables are devoid of ornamentation. This division can be noted with varying clarity throughout the history of furniture.

At times the ornamentation itself has, in a sense, been functional. The decoration of the earliest examples of furniture from Mesopotamia and Egypt, for example, had a symbolic or magical function. The legs of Sumerian stools are shaped like those of an ox, which was the guardian animal of the city of Ur. Egyptian furniture shows a much wider development of furniture legs based on animal models. Three-footed stools ending in dogs' paws, folding stools with legs in the shape of ducks' heads, and bed legs in the form of lions' feet are known from a thousand years of Egyptian furniture history. Tables with lions' legs can be seen on Assyrian reliefs. Similar animal symbols are known from representations of Greek furniture. Sometimes the arms as well as the legs of Greek chairs had animal shapes—terminating, for example, in the head of a lion or a ram. It is thought likely that ceremonial seats and thrones featured animal motifs partly as a magical expression of the transference of power. This ancient tradition lived on in European furniture; for example, in thrones, where griffons, lions, and eagles played a prominent part in the decoration.

Even in the furniture of antiquity it is difficult to differentiate between the symbolic and the aesthetic in decorative features. It is clear, however, that the animal world has always been one of the primary sources of ornamental motifs in furniture. Animal legs and heads are found, for example, as terminal decorations in the French Rococo chair and imitations thereof. The animal leg played a prominent part in English furniture of the 18th century and later passed into American furniture. English cabinetmakers and chair makers devised a naturalistically carved lion's foot and a characteristic claw-and-ball foot, a motif that may stem from Chinese forms of ornamentation (not, however, on furniture) such as the dragon's claw holding a ball or a pearl. Richly carved English mahogany chairs sometimes also feature the heads of birds, lions, or dogs as terminal decorations on the arms. Although the majority of Chinese chairs and tables are supported by straight legs of rounded wood, Chinese thrones and seats for dignitaries have curved legs that, for some unknown reason, may be imitations of elephant trunks.

Animal and architectural motifs

Next to the animal world—and of more recent origin—architecture is the most important source of decorative motifs in furniture. In the late Middle Ages, the perpendicular tracery of Gothic architecture was transferred through the craft of the wood-carver to the fronts of chests. Italian chests and walnut cupboards of the same period were modelled on the marble sarcophagi of classical antiquity, which are entirely architectonic in form. During the Renaissance and Baroque periods the column was introduced as a strikingly decorative frontal feature in the form of table legs and on cupboards. The fronts of very big, heavy cupboards particularly lent themselves to architectonic composition corresponding to the portals and gables of houses (Figure 54). At about the same time, the ornamental wealth of the Renaissance broke through in rosettes, cupids, and fruits on panelling and frames.

During the Court Baroque period under Louis XIV in France, the royal official style left its mark not only on ornate pieces of furniture but also on panels, doors, mir-

ror frames, and, indeed, even on the facades of palaces and châteaus and the layout of formal gardens. The coherence between interior and furniture was even more pronounced during the Rococo period and under Louis XVI, culminating temporarily in the furniture and rooms of the French Empire style.

The 19th century often seems to have offered nothing more than a breathless repetition of this coherence between the ornamental design of furniture and the architecture of the interior—both revivals of the styles of the past. A new style did not arise until the close of the century. French Art Nouveau furniture, with its gliding vegetable forms, must be seen in conjunction with the houses and rooms for which it was executed. The furniture of Antonio Gaudí, a Spanish architect and designer, for example, had a profound coherence with his own buildings; and the strangely expressive and stylized furniture of a Scottish architect, Charles Rennie Mackintosh, forms an integral part of his buildings and interiors in Glasgow.

Art Nouveau furniture

The influence of architecture on furniture can also manifest itself in a lack of ornament. There is a relationship, for example, between functionalistic architecture as it was first manifested in the 1920s at the Bauhaus in Germany and steel furniture designed by the German architect Mies van der Rohe.

KINDS OF FURNITURE

Chair. Of all furniture forms, the chair may be the most interesting. While most other forms (except the bed) are intended to support objects, the chair supports man. The term chair is used here in the widest sense, from stool to throne to derivative forms such as the bench and sofa, which may be regarded as extended or connected chairs, and whose character (*i.e.*, whether they are intended for sitting or reclining) is not clearly defined.

The social history of the chair is as interesting as its history as an art and craft. The chair is not merely a physical support and an aesthetic object; it is also an indicator of human worthiness. One is offered a chair; one does not just sit down anywhere at all without being asked to do so. Chair forms may also involve an indication of rank. At the old royal courts there were social distinctions between sitting on a chair with arms, on a chair with a back but no arms, and having to make do with a stool. In the 20th century, the director's or manager's chair has been an indicator of superior dignity, and even in democratic parliaments the speaker sits on a raised level.

As a furniture form, the chair encompasses a wealth of variations. There are chairs designed to match man's age and physical condition (the high chair, the wheelchair) and for his position in society (the executive chair, the throne). In the olden days there were chairs to be born in (birth chairs); in the 20th century, there have been chairs to die in (the electric chair). There are chairs with one, two, three, and four legs, chairs with or without arms, and chairs with or without backs. There are chairs that can be folded up, chairs on wheels, and chairs on runners.

Modern living has developed special chairs for automobiles and aircraft. All of these chair forms have been evolved to conform to changing human needs. Because of its close association with man, the chair appears to its full advantage only when in use. Whereas it makes no difference to one's appreciation of a cupboard or a chest of drawers whether there is anything inside or not, a chair is best seen and evaluated with a person sitting on it, for chair and sitter complement one another. Thus the various parts of a chair have been given names corresponding to the parts of the human body: arms, legs, feet, back, and seat.

Because the basic function of the chair is to support man, its value is judged primarily on how well it fulfills this practical role. In the construction of a chair, the designer is bound by certain static laws and principal measurements. Within these limits, however, he has great freedom.

The history of the chair covers a period of several thousand years. There are civilizations that have created distinctive chair forms, expressive of the highest endeavour in the spheres of technique and aesthetics. Among such cultures, special mention must be made of ancient Egypt and Greece; China; Spain and Holland in the 17th century; England in the 18th century; and France in the 18th century during the reigns of Louis XV and Louis XVI.

Egypt. Two ancient Egyptian chair forms, both the result of careful design, are known from discoveries made in tombs. One of these is a four-legged chair with a back, the other a folding stool. The classical Egyptian chair (Figure 55) has four legs shaped like those of an animal, a curved seat, and a sloping back supported by vertical stretchers.

The classical Egyptian chair

Figure 55: Golden throne from the tomb of Tutankhamen at Thebes, wood overlaid with gold and inlaid with faience, glass, and calcite, Egypt, 18th dynasty, c. 1350 BC. In the Egyptian Museum.

In this way a strong triangular construction was obtained. There was apparently no marked difference between the construction of Egyptian thrones and chairs for ordinary citizens. The main difference lies in the decorative ornamentation, in the choice of costly inlays. The Egyptian folding stool probably was developed as an easily portable seat for officers. As a camp stool the form persisted until much later times. But the stool also took on the character of a ceremonial seat, its mechanical function as a folding stool being forgotten. This can already be observed, from as early as 1366–57 BC in two stools, executed in ebony with ivory inlay work and gold mounts, from the tomb of Tutankhamen. They are in the form of folding stools but cannot be folded as the seats are of wood. The simple construction of the folding stool, consisting of two frames that turn on metal bolts and support a seat of leather or fabric fastened between them, reappears somewhat later in the Bronze Age folding chairs of Scandinavia and northern Germany. The best known of these is the folding stool, made of ashwood, found at Guldhøj (National Museum in Copenhagen).

Greece and Rome. The typical Greek chair, the klismos, is known not from any ancient specimen still extant, but from a wealth of pictorial material. The best known is the klismos depicted on the Hegeso Stele at the Dipylon burial place outside Athens (*c.* 410 BC) (Figure 52). It is a chair with a backward-sloping, curved backboard and four curving legs, only two of which are shown. These unusual legs were presumably executed in bent wood and were therefore subjected to great pressure from the weight of the sitter. The joints fastening the legs to the frame of the seat are therefore very strong and clearly indicated.

The Romans adopted the Greek chair; a number of statues of seated Romans show several examples of a heavier and apparently somewhat more crudely constructed klismos. Both types, the light and the heavy, were revived during the Classicist period. The klismos chair is found in French Empire furniture, in English Regency, and in special forms of considerable originality in Denmark and Sweden around 1800.

China. The ancestry of the chair in China cannot be traced as far back as in Egypt and Greece. Since the T'ang dynasty (AD 618–907) an unbroken series of drawings and paintings has been preserved showing the interiors and exteriors of Chinese houses and their furniture. Also preserved since the 16th century are a number of chairs of wood or lacquered wood that bear an astonishing resemblance to representations of older chairs.

Two major Chinese chair forms

As was the case in Egypt, there were two major chair forms in China: a chair with four legs and a folding stool. The four-legged chair is found both with and without arms but always with a square seat and straight stiles (upright side supports) to support the back. In one form, however, the stiles are slightly curved above the arms so as to conform to the rhythm of the S-shaped back splat (the central upright of a chairback). All three parts are mortised into the yoke-like top rail. While the design of the back splat exercised an influence on English chairs of the Queen Anne period, wooden members that only to a limited extent reinforce corner joints (and are loose into the bargain) represent a feature exclusive to Chinese chairs. The four legs pass through the seat frame, which closes about the rounded staves. All members are round in section or have rounded edges—it is as though one can just discern a bamboo tradition hovering in the background. The seat is uncomfortable and may have a plaited bottom. These chairs must have required the sitter to remain stiff and upright; for if too much pressure is exerted on the back, the chair has a tendency to topple over. In patriarchal Chinese homes of this period armchairs presumably were reserved for the senior members of the family, for they were held in great esteem.

The Chinese folding stool is presumed to have travelled to China from the West. It does not differ so very much from the Egyptian or Scandinavian folding stools, but it has a variation in that the top rail is elegantly joined to the two legs of the stool by means of a curved member, which is often provided with metal mounts. From a Western viewpoint the overall effect of both these furniture forms is stylized. The constructive and decorative elements are combined in a manner that is simultaneously naïve and refined. The pieced-together appearance is a result of the fact that the individual members do not appear to have been joined together with either glue or screws, but have been mortised into one another and locked into position in the manner of a Chinese puzzle.

Spain: 17th century. The Golden Age of Spain during the 17th century also left its mark on the chair. Paintings show a type of chair with a relatively crude wooden frame; a back and seat, nailed on, consisting of two layers of leather, with horsehair stuffing in between, stitched to produce a pattern of small pads. The front board and a corresponding board at the back could be folded after loosening some small iron hooks. Thus the chair was an easily portable piece of furniture for travelling which, at the same time, had the dignity of a four-legged, high-backed armchair.

Holland: 17th century. A low, square, upholstered type of chair can be seen in engravings of interiors of affluent Dutch homes by Abraham Bosse, a French artist (Figure 56), and in paintings by the Dutch artists Jan Vermeer and Gerard Terborch. Although this kind of chair is also found in countries where Dutch styles of interior decoration and Dutch furniture won favour, it is not certain that the form actually originated in Holland. Normally, the legs of the chair are smooth, round in section, and of slender dimensions; they are sometimes balustershaped (vase-shaped) or twisted. It is clearly a bourgeois piece of furniture and was made in considerable numbers, as can be seen from one of Abraham Bosse's engravings, in which a whole row of such chairs has been lined up against a wall. The form asserts itself by virtue of its harmonious proportions and fine upholstery in gilt leather or fabric bordered with fringes.

France and England: 17th and 18th centuries. The French Rococo chair in its most mature form—that is, as developed in Paris around 1750—spread over most of Europe and has been imitated or copied into the mid-20th century. The model owes its popularity to a combination of comfort and elegance. The seat conforms to the human body and permits a relaxed sitting position. The back is bow-shaped, the legs curved. Normally the seat and back are upholstered, and there are small upholstered pads on the armrests. Smooth transitions achieved between seat frame, legs, and back disguise all the joints, which are solidly constructed on craftsmanlike principles despite the absence of stretchers between the legs.

French Rococo chair

French Rococo chairs and imitations thereof employ wood of fairly thick dimensions; but all members are deeply molded, all superfluous wood has been cut away, and finer examples may be further embellished with very delicate and decorative carving. The wood may be left in

its natural state, painted, or gilded. Silk damask or tapestry is used for the upholstery on the seat, back, and armrests; canework is sometimes used in place of upholstery.

English chairs of the 18th century are more differentiated in design than the French. The French taste for stylistic uniformity, which spread from the most distinguished circles in Paris and Versailles over most of France and won favour in several parts of the Continent, had no parallel in England. Prior to 1740, the most commonly used wood was walnut; thereafter, and for the rest of the century, it was mahogany. Walnut, though beautiful in hue, was soft and therefore less suited to wood carving than to rounded, curving forms. Outer surfaces, such as the back and seat frame, were usually veneered. During the walnut period, highly overstuffed armchairs, covered with leather or embroidered material, were also developed. The best upholstery of this period is precisely and firmly modelled and accentuated by braiding or tacks. When imports of mahogany became common, no specifically new chair designs appeared, but the character of the woodwork changed. Mahogany, having a firmer, closer grain, could be cut thinner, which meant that individual parts of the chair could be more slender in shape. Mahogany also lent itself better to carving than walnut. Carving was concentrated more on the arms and back than on the legs, which as a rule were straight and smooth with chamfered (bevelled) edges and molding. There was a wealth of variety in chairback designs, featuring elegant, pierced, vase-shaped splats or two upright posts connected by horizontal slats (ladderback).

Stick-back chair

Alongside the French Rococo chair and the best English chairs in walnut and mahogany, the more countrified stick-back chair was relatively unaffected by the stylistic changes of the day. Originally a medieval form, known, for example, from paintings by Pieter Bruegel the Elder and still found in mid-20th century in the churches and inns of southern Europe, the stick-back chair (in all of its variations) consists basically of a solid, saddle-shaped seat into which the legs, back staves, and possibly the armrests are directly mortised. This typically peasant form underwent a renewal and a process of refinement in England and America during the 18th century. Under the name Windsor chair (a term that seems to have been used for the first time in 1731) or Philadelphia chair, it became well-known and was widely distributed throughout the world. Related in form to the Windsor chair is an American chair made by members of the Shaker sect in the workshops they set up in their small, closed religious communities. Some of the best examples of these were executed around the middle of the 19th century at the Shaker headquarters in Pennsylvania.

Late 18th to 20th century. During the Neoclassical period, no basic changes took place in chair forms, but legs became straight and dimensions lighter. Backs in the shape of classical vases replaced the fanciful outlines of the Rococo period. Around 1800, freely executed imitations of Greek and Roman chairs of the klismos type, with curved legs and backrest, appeared. French chairs of the Empire period, executed in dark mahogany and embellished with ornate bronze mounts, created a ponderous effect.

In cheaper versions of inferior workmanship, bourgeois chairs of the 19th century carried on the traditions of the 17th and 18th centuries. The only real innovations were the bentwood (wood that has been bent and shaped) chairs in beech that became popular all over the world and are still made in the 20th century (Figure 57). Around 1900 the continental Art Nouveau and *Jugendstil* styles

(French and German styles characterized by organic foliate forms, sinuous lines, and non-geometric forms), and the Arts and Crafts movement in England (established by the English poet and decorator William Morris to reintroduce standards of medieval craftsmanship), gave rise to original chair designs by Eugène Gaillard in France, Henry van de Velde in Belgium, Josef Hoffman in Austria, Antonio Gaudí in Spain, and Charles Rennie Mackintosh in Scotland. These new furniture styles did not exercise wide, let alone decisive, influence. The Art Nouveau chairs designed by the French architect Hector Guimard, for example, are collector's pieces, but his name is known to a broader public only because of his fanciful entrances to the Paris Métro.

Modern. After World War I, the Bauhaus school in

Germany became a creative centre for entirely revolutionary thinking, resulting, for example, in tubular steel chairs designed by the architects Marcel Breuer, Ludwig Mies van der Rohe, and others (Figure 58). During World War II, the aircraft industry accelerated the development of laminated wood and molded plastic furniture. The dominant chair forms of this period go back to designs by a Finn, Alvar Aalto, Brun Mathsson, and an American, Charles Eames (Figure 58). Rapid technical developments, in conjunction with a severance from all tradition, suggest that completely new chair forms will probably be evolved in the future.

Table. *Fixed and mechanical tables.* In general, tables can be divided into fixed and mechanical types. The fixed table, consisting of a square or round top supported by one or more legs, is the least complicated from the viewpoint of craftsmanship. It is a form that requires wood of thick dimensions in order to make the joints by which the top is fastened to the legs strong enough to resist lateral pressure. Old Spanish or Italian tables are often constructed with sloping stretchers to counteract this pressure. The simplest way to make a table steady without exaggerating the dimensions of the individual parts is to fasten the legs to an underframe. Fixed tabletops can also make

Pedestal table

do with a single leg; for example, the so-called pedestal table, terminating in a tripod or quadripod. Pedestal tables topple over easily, however, unless both top and pedestal are particularly heavy. Three-legged tables with a fixed top provide a more reliable support than a single-legged type but are unstable when subjected to uneven pressure from above.

The term mechanical refers to all tables whose tops can be enlarged or reduced according to need. Such tables may require pivotable or collapsible legs to augment the strength of the top. A familiar solution to the extension of a tabletop is the so-called Dutch system, known since the 17th century from Dutch engravings and paintings, in which the extension leaves, when pulled, slide out on sloping runners. When the leaves have been fully extended, the top is lifted and then dropped into place. The table height remains the same. The construction demands great accuracy and skill on the part of the craftsman. There are also more complicated forms of extension tables with runners enabling the legs as well as the leaves to be drawn out; extra leaves can then be inserted.

Tables with flaps also are constructed to take up less space when folded away and can be variously made, either with flaps that are supported by brackets that swing out on hinges or on so-called gate legs. During the 18th century, England was a leader in the design of ingenious folding tables, especially card tables. In the gateleg card table, the top can be folded so as to occupy half the space, and when opened is supported by a leg that swings out like a gate. In another system, the square underframe can be extended to form a rectangular top, the two sides being divided by hinges. On modern card tables, all four legs can be folded up within the frame surrounding the top; when not in use, the tables can therefore be stored easily.

Gateleg table

Historical forms and styles. Round stone tables on low pedestal legs are known in Egypt from the time of the pyramids (*c.* 2700 BC). Egyptian limestone reliefs also show tables of normal height. Dating from the later dynasties, crude wooden tables with architectonic molding have been preserved. No tables have survived from ancient Greece. From the Roman ruins of Pompeii and Herculaneum, however, there are examples of monumental table supports or side members made of marble decorated with relief work and metal tables (Figure 64), many of them of the folding type. All wooden furniture has been lost, however.

Several wooden-topped communion tables dating from the early Middle Ages still stand in churches, hidden by altar cloths or built into boxes. Usually, such tables rest either on solid masonry or on a stone socle (a projecting member beneath the base of a superstructure), but they are sometimes elegantly supported by several columns. Generally, communion tables are made of stone, and since one stands before them, they are higher than the usual table. Examples of wooden tables preserved from the late Middle Ages are, as a rule, long narrow tops fastened to side members.

The interesting feature about the tables of the Renaissance and Baroque periods is their constructive and aesthetic design. Their thick and heavy tops rest on an underframe; the legs are baluster-shaped or turned, with deeply carved bulbous decoration. In the 17th century and later, table forms were widely differentiated and made for a great variety of purposes; *i.e.,* dining tables, library tables, drawing-room tables, card tables, tea tables, small candlestick tables, sideboards, and console tables.

Ming forms

From the Ming dynasty and the 18th century, several interesting Chinese fixed-top table forms have been preserved, in which the constructive elements are in some cases emphasized and in others deliberately disguised. Like other Chinese furniture forms, the tables create a stylized effect, with a naïve, calculated character. Chinese tables may be completely covered with lacquer and gilt ornamentation, but sometimes the wood is left in its natural colour.

Bed. In Homer's *Odyssey* there is a description of how Odysseus made his own bed: the trunk of an olive tree was cut to the exact shape and planed smooth; after holes had been drilled in the framework, oxhide thongs, dyed crimson, were threaded back and forth to make a pliant web; finally, the wood was embellished with inlay work in gold, silver, and ivory.

As a furniture form, the bed is as old as the chair. In principle the construction of the bed is extraordinarily simple: it consists merely of a rectangular platform raised in some way or other slightly above floor level. A considerable number of bed forms cannot be classed as furniture at all. Alcoves and bunks in ships, railway carriages, and airplanes belong more to the sphere of building trade joinery than to cabinetmaking.

That a number of beautiful and original bed forms of fine artistic execution have been created since antiquity is attributable to the fact that the bed gives the furniture designer rich possibilities in terms of framing and presentation, particularly in conjunction with textiles. Apart from the actual bedclothes, which will always be of greater importance than the actual platform and the surrounding framework, imaginative experiments combining the practical and the impressive—in four-poster beds and tentlike canopies, for example—have been made for centuries.

An Egyptian bier dating from the 1st dynasty (*c.* 3100–2890 BC) shows the original form of the bed: a rectangular framework of staves, round in section and mortised into one another so as to leave the ends free lengthwise, supported on four small legs carved to represent stylized lions' feet. Amusingly, the feet face in the same direction—as if they were walking with the dead person. This is characteristic of all Egyptian beds. Made of cedarwood, the light framework is higher at the head than at the foot; and whereas the foot is always terminated by a footboard, there is no board at the head. The beds were so constructed because the Egyptians when sleeping or resting used a stool-like support for the head (Figure 62). Essential to the Egyptian bed, countless examples of this piece of equipment—made usually of wood but sometimes of

ivory and faience—have been found in Egyptian tombs. The actual framework of the bed was often covered with plaited leather thongs.

In China, a bed in the form of a complete little house, with an anteroom in the form of a veranda, was placed in the middle of the room.

Before central heating and a knowledge of hygiene became common, the closed bed was the generally accepted form in cold climates. The simplest way to avoid drafts was to place the bed in an alcove—as was the practice in farmhouses right up to the 19th century. The most frequently encountered form of bed in European civilization, however, was the four-poster. Throughout the Middle Ages and later, the four-poster was developed in a variety of forms. Already during the Middle Ages, beds were designed for clearly ceremonial effect. The four posts supported an expanse of cloth that extended from the head like a canopy, just as the most distinguished row of choir stalls in a church was crowned by a baldachin (an ornamental structure resembling a canopy). Miniatures in illuminated manuscripts of the same period show tentlike beds entirely closed by drapery and curtains.

The four-poster

In the time of the absolute monarchies in the 17th and 18th centuries, pompous four-posters were developed in which the surrounding textile drapery completely concealed the wooden construction of the bed, thereby achieving a synthesis of practical and ceremonial considerations. Every palace or mansion had a chamber of state among its official reception rooms. Contemporary memoirs describe the complicated ceremony that took place at Louis XIV's daily awakening. Where his royal highness spent the night was his own concern, but his awakening was an act of state, in the conduct of which princes of the blood, dukes, and distinguished courtiers all had their respective duties: one would draw aside the bed-curtain, another would have the royal dressing gown ready, another the royal slippers. It was the first audience of the day, the king's levee. A large number of 17th- and 18th-century four-poster beds are still preserved in palaces, country houses, and museums; and most of them have a clearly dramatic, almost theatrical effect (Figure 60). The four-poster beds of the Baroque and Rococo periods, moreover, reflect great artistic refinement, especially in the rare instances in which they can still be seen in their original interiors complete with their entire textile adornment. Such beds of state are typical of continental Europe. In England and America, particularly toward the end of the 18th century, greater interest was taken in showing off the bedposts and the upper framework connecting them. Many English four-posters have slender, finely carved mahogany posts, whereas on the Continent the corresponding parts may be entirely covered with the same silken material as that used for the curtains, canopy, and bedspread.

Empire bed

During the Empire period in France an entirely new form of bed was developed and won favour throughout most of Europe. The design was inspired by the Roman couch as known from reliefs and from excavations in Pompeii and Herculaneum. The frame was very high, and the bed ends consisted of volutes (spiral or scrollshaped forms) of equal height. The bed was crowned by a tentlike superstructure, and the martial aspect was further emphasized by the use of spears to support the draperies and curtains; the whole bedroom, in fact, might well be draped like a tent (Figure 40). In these surroundings, the army commanders of Napoleon's time could feel like the caesars and consuls of ancient Rome. During a campaign, however, collapsible iron camp beds were more practical. Napoleon owned several and died in one on St. Helena in 1821. As a furniture form, the iron bed was a neutral framework built to support bedclothes and equipped with stanchions (upright supports) for curtains; it was light, transportable, and spartan.

Among plantation owners in the West Indies and the southern United States, a type of four-poster popular at the beginning of the 19th century was dominated by wood, rather than textile hangings. The posts supported very light, roughly made wooden frames, to which thin, white mosquito netting was fastened to protect the sleeper. The monumental and dignified effect was obtained by the quality of the woodwork. Of thick dimensions, the wood is

solid mahogany polished to a high gloss. The four bedposts are not necessarily identical at the head and foot of the bed, but all have bulbous and turned sections, exaggerated almost to the point of crudeness. The headboards and footboards are imaginatively designed with voluted gables (triangular decoration) and galleries (ornamental railings) supported on pillars. Besides the practical function of these West Indian beds, they also served to indicate the importance of their owner; like the royal four-poster of the days of absolute monarchy, they clearly showed the difference between master and slave.

In the 20th century, the bed has belonged exclusively to one's private life; and compared with those of the past, modern beds are simple. Four-posters are still "modern," possibly because they appeal to something primitive, namely the sensation of sleeping in a tent. In general, development has been concentrated on improving the quality of bedclothes and increasing the amount of comfort by attention to springs, spring mattresses, eiderdowns, and pillows. The actual woodwork of the bed is usually restricted to joined veneered sections of laminated board, canework sometimes being used for the headboards and footboards.

Storage furniture. *Chest.* The chest, including the coffin (and sarcophagus), is an ancient primitive furniture form that has survived into the 20th century. The design of a clothes chest is optional; its size depends on changing demands. The construction of a coffin, on the other hand, is a set task. The format is determined by certain principal dimensions, and the human figure has at all times exercised an influence on the shape of the coffin; the Egyptian mummy case, which takes on the form of the swathed corpse, is an example. Traditional features of ancient Roman sarcophagi, and simplified versions of the monumental style of the Baroque and Renaissance periods continue to thrive.

Early medieval chests

The principal constructional features of early medieval chests lasted until the Renaissance. The so-called Oseberg ship, dating from the Viking era (9th century AD) and discovered in 1904 in Vestfold, Norway, included among the furniture on board a chest made of oak planks secured by iron bands. The planks are not mortised together, and the end sections stand vertical, thereby forming feet, wider at the bottom than above. The lid is formed by a single curved oak plank that has been roughhewn into shape. The bottom of the chest rests in a groove cut into the end sections. The wooden construction, a primitive form of carpentry, is held together by broad iron bands, the nails are tin-plated. In this Oseberg chest, the iron mounts essential to the construction constitute the decorative element as well. All medieval chests are developments of the same principle: a piece of carpentry with decorative iron mounts, but the principle found freer application in medieval church doors than in the chests of the period.

The chest often appears in portable form as a traveller's trunk that can also serve as a stationary piece of furniture. A number of painted, parchment-covered Florentine chests dating from the middle of the 15th century have been preserved. These were used as trunks by young girls on their way to enter a convent and later stood in their cells as pieces of storage furniture for clothes and other personal belongings. A "nun's chest" of this type is in principle quite different from the sumptuous cassoni of the Italian Renaissance that were adorned with gilded stucco work and painted panels (Figure 61). Cassoni were stationary pieces of palace furniture. Specifically designed for travelling, however, were Javanese camphorwood chests that made the long voyage round the Cape of Good Hope full of stuffs and spices and eventually came to rest in an English manor house or in a gabled Dutch mansion in Amsterdam. The plank construction with metal mounts is of primitive craftsmanship. The large, smooth expanses of reddish-brown wood, with their elaborate openwork brass mounts and big, chased bolt heads to take the brunt of rough handling, have a kind of sophisticated crudeness about them. On later camphorwood chests the brass mounts are sunk flush with the surface of the wood, just as on portable writing desks and toilet cases of the French Empire period. Veneered wood was not suitable for chests intended for travel purposes, but it was possible to cover the entire chest with leather fastened with metal nails, possibly to form a pattern. Several beautiful, leather-covered chests made in Italy and Spain in the 17th century are known, and the form persisted in the large wardrobe trunks of succeeding centuries.

"Nun's chest"

When furniture-making techniques demanding the skill of the cabinetmaker evolved during the Renaissance, frames, panels, and carving appeared on chests. In southern Europe, walnut lent itself admirably to carving; in northern Europe, oak. While the Italians were inspired by the molding and decorative plant ornamentation of the stone sarcophagi of ancient Rome, in northern Europe late medieval wood carving traditions were continued. As a rule the carved woodwork was picked out (trimmed) with paint and gilded. In the 18th century, the chest was largely supplanted for storage purposes by the chest of drawers and the commode (low chest of drawers), but it never entirely disappeared. Particularly in the big country houses of England and America, chests of mahogany or walnut were used for a long time, often having drawers in the bottom and finely fashioned brass mounts that revealed Chinese influence.

Cupboard. Strictly speaking, the cupboard is a derivative form of the chest. Early Renaissance cupboards resembled two chests placed one on top of the other, but they were opened from the front by means of doors. The design and construction of the cupboard's pronounced front have always provided ample scope for artistic composition, and it is no mere coincidence that the cupboard more than any other furniture form should have closer links with architecture. It literally invited an architectonic composition: socle, columns, cornice. This development can be traced from the close of the Middle Ages in a large number of southern German and Tirolean cupboards bearing late Gothic perpendicular tracery and smooth surfaces veneered with ashwood. Very large cupboards took

on their most striking form, however, during the Renaissance in 17th-century Holland and northern Germany. In molding and composition, they have much in common with architectural facades, but their picturesque and textural effects are the result of refined craftsmanship. The use of veneer was almost essential if these large expanses of wood were to be infused with life. A carcass of wood was given a veneer of fine walnut; socle, frames, columns, and cornice were decorated with veneered black ebony. The doors were furnished with strong locks, and the keyhole was concealed behind a sliding middle column. The cornice was often decoratively crowned with a set of Dutch faience or Chinese porcelain vases. These heavy cupboards were made to appear lighter by placing them on big, turned ball feet. In marked contrast to the European Baroque cupboards, Chinese cupboards of the same period were simple, smooth-surfaced, and boxlike. Their construction was based on a simple system of uprights and frames, and as a rule they were made in pairs. If painted, a large decorative painting was spread across the entire surface, including the doors. Inside, Chinese cupboards are finished with great care and painted in a different colour from the outside. The mounts are of various white and yellow metal alloys, smooth, either round or square; and the locks are secured with prismatically designed padlocks. Japanese and Siamese cupboards, apart from certain independent features, follow the old Chinese traditions.

Chinese cupboards

The clothes cupboard of the 19th and 20th centuries, an indispensable piece of bedroom furniture wherever there are no built-in cupboards, is based on traditional features of the 18th-century English clothespress but equipped to meet the changing fashions of modern times.

Bookcases. Bookcases or bookshelves are a less interesting form of storage furniture from the viewpoint of furniture history. Perhaps the most significant innovation appeared in 18th-century England in the bookcase with adjustable shelves and a closed-off lower section for folio files. The shelves were protected by glass doors consisting of an ingenious trelliswork of carved wood. Bookcases and shelves become interesting only when they form part of specially designed library interiors and when several shelves full of books create an intimate, compact whole.

Mixed forms. Apart from the kinds of storage furniture already mentioned, there are numerous combination forms. An ordinary table can be used as a writing desk, and the only differences between the typical French Rococo writing desk of the 18th century and other tables are the drawers in the underframe and the leather-covered top. The novelty of Louis XV's writing desk consists of a rolltop device for closing the writing flap. In England a special type of writing desk was developed which, besides drawers in the underframe, has a side cupboard fitted with additional drawers and, occasionally, sliding trays. Some have a false drawer front that can be pulled out to form a writing surface. When a writing desk has a cupboard built on the top of it and is placed on a chest of drawers, the result is a cabinet or secretary. There are also bookcases with lower sections equipped with a flap, either hinged or sliding, for writing. All of these combinations, frequently of ingenious design, were made anonymously in England during the 18th century, apparently having arisen from a desire on the part of the well-to-do middle classes to develop a sophisticated and differentiated pattern of life.

English writing desks

A special group of storage furniture embraces the various forms of corner furniture, low or high cupboards that were made in pairs (just as in the case of several other old furniture forms) particularly for small rooms, in which they became fixed components of the interior scheme.

Kitchen furniture and furnishings. Kitchen furniture and furnishings go back to antiquity. In the Middle Ages, the kitchen, with its fireplace, was the most centrally placed room in the home. Later, closed fireplaces were constructed in the form of stoves; and cupboards, sinks, and plate racks were fixed to the wall. The kitchen in a modern home, if not combined with a dining area, is a small room filled with equipment. On the other hand, institutional kitchens have expanded enormously. Outdoor cooking equipment, such as various forms of open-air grills, also forms part of modern kitchen furniture.

Bathroom furniture and fixtures. Bathrooms in large private homes were not unknown in the 18th century, and splendidly equipped marble bathrooms are still preserved in several European palaces and mansions. But not until the 19th century did bathrooms in private homes become more commonplace. Fixtures generally include a toilet, bidet, washbasin, bath, mirror, and shelves. In the 20th century the equipping of bathrooms became a separate industry with a wide variety of special forms of bathroom furniture and fixtures. The materials used are porcelain, enamel, plastic, wood, and stainless steel.

Specialized furniture. Office furniture in the widest sense of the term has undergone rapid developments since mid-19th century. Such pieces as the high desks used by clerks in old offices and the big American rolltop desks have been replaced by carefully designed standard forms of writing desks with side cupboards, typewriting tables, filing cabinets, and office chairs with adjustable backs and swivel seats. From office furniture one passes naturally to the vast sphere of institutional furniture: theatre furnishings in the form of rows of connected seats, restaurant furniture, furniture for conference rooms, laboratories, workshops, and factories. Several of these specialized furnishings reflect past traditions. The way in which the British House of Commons is furnished, for example, derives without doubt from the pattern in which choir stalls were grouped in medieval churches; whereas the semicircular, often amphitheatrically designed assembly halls of the United States Congress and the parliaments of many European countries are developed forms of academies of surgery or other university auditoriums. Similarly, museums, libraries, and archives have their special furniture in the form of showcases, desks, special tables, and socles.

Office furniture

There are also furnishings for movable premises, primarily railway carriages equipped for sleeping or dining, passenger ocean liners with cabins, airplanes, buses, coaches, and private cars.

Finally, there is the large, highly heterogeneous group comprising outdoor or open-air furniture; for example, furniture for gardens, balconies, terraces, and solaria.

KINDS OF ACCESSORY FURNISHINGS

Besides the aforementioned kinds of furniture and all the many special forms (which it would be almost impossible to list), there is an extensive group of accessory furnishings that is not furniture in the strict sense but, nevertheless, constitutes an important element in the furnishing of interiors. Included here are clocks and other mechanical works, mirrors, textiles, screens, stoves, and fireplaces; and a number of smaller articles made by cabinetmakers, such as boxes, caskets, sewing tables, wastepaper baskets, lighting fixtures, frames, panelling, and floor surfaces.

Clocks. Clocks are considered furnishings if the movement is enclosed within a case, which need not necessarily be of wood. Clocks can be divided into table clocks and long-case clocks. There were two creative centres for table clocks, namely England and France. In 17th- and 18th-century France, the table clock became an object of monumental design, the best examples of which are minor works of sculpture. The actual movement is framed by a marble socle, and the clockface by a sculptural frame of solid bronze incorporating freely molded figures and ornamentation. Some of France's best sculptors and bronze casters were engaged in the creation of decorative frames for clock movements. A French speciality, imitated elsewhere on the Continent, was the wall clock, or so-called cartel clock, the earliest examples of which were designed by a goldsmith and ornamentalist, Juste Meissonnier. The clockface is the centre of an ornament, or rocaille-cartouche, cast in bronze, sometimes garnished with figures of symbolic significance; for example, Time, a man with a scythe, or a crowing cock. In England, where tastes were more bourgeois, the fine movements made by skillful London clockmakers were built into wooden cases, architectonic in composition and featuring pilasters (partly recessed columns) and cornices. Simple walnut cases could be adorned with metal ornaments and brass balls. The more expensive table clocks were concealed in cases embellished with inlaid wood or tortoiseshell.

Table clocks

Long-case clocks

Long-case clocks were also made in France and England. French long-case clocks are monumental and richly designed. In the reign of Louis XIV there were long-case clocks of the boulle type with metal and tortoiseshell inlay work. Later, in the 18th century and especially during the Rococo period, the case that concealed the weights acquired more dramatic form: richly inlaid wooden surfaces were framed and adorned by magnificently gilded Rococo ornaments in bronze. The English long-case clock was to a greater extent a piece of furniture, and the main features of its construction remained unaltered throughout the 18th century. The longcase clock stands on a base, or socle, from which the somewhat narrower case for the weights rises up, crowned by the framework of the actual movement and clockface. The last-named section is in reality a table clock mounted on a weight case. Each individual section of the long-case clock is thus clearly separate; each has its distinct function; and no attempt was made, as in France, to veil the independence of the individual parts. The weight case is provided with a door in which there may be a window through which the position of the weights can be observed.

During the 18th century, barometers became increasingly popular. The mechanism was provided with a decorative wooden framework intended to harmonize with the other furniture in a room.

Mirrors. The use of mirror glass in furnishings arose during the 17th century. The discoloration of the melted glass because of silvering and, not least, the prohibitive cost and difficulty of manufacturing mirror glass of considerable size restricted the possibilities of large-scale application. The mirror gallery at Versailles (Figure 27) was thus an outstanding technical achievement for its time. When Louis XIV strode through the gallery at the head of his court, the glass walls reflected the diamonds in his crown. This effect was imitated to a greater or lesser degree in all the courts of Europe. In the 18th century the wall mirror found its way into most interiors. The popularity and wide distribution of mirror glass was stimulated by the need for an increased amount of artificial light. During the 16th and 17th centuries, this need had been satisfied by placing candles in front of highly polished concave metal plates. By using silvered mirror glass, the light effect was multiplied. From then on, large mirrors hung over console tables were a necessary and functional part of rooms illumined by artificial light.

Mirror gallery at Versailles

Fabrics. The use of fabrics in furnishing rooms is closely bound up with the need for heating. In the primitively heated rooms of the Middle Ages, textiles were used to keep out cold and drafts. In 12th- and 13th-century churches, painted textile drapery can still be discerned beneath the picture friezes. In rather cold churches, just as in poorly heated homes, loosely hung textile wall coverings were of the greatest importance. They were hung loosely because of the practice of taking them down and moving them, together with the relatively few items of furniture, according to need. It was not until the end of the 17th century and during the 18th century that tapestries and other forms of textile wall hanging became fixtures; that is, fastened to the wall within frames. Wall pictures made of paper and, subsequently, patterned wallpaper became a cheaper substitute for textile wall hangings during the 19th century. Screens or room dividers were often covered with textiles, partly to afford protection against direct radiant heat and partly to create cozy corners in large rooms. Framed screens were often covered with pieces of tapestry, with other woven materials, or with gilt leather. (See the section *Tapestry* below.)

Portable wall hangings

Fireplaces. The heating of rooms and large halls remained a major problem until the advent of modern central heating systems. The open hearth was replaced during the late Middle Ages by the fireplace, which is merely an architectonic way of framing the burning logs. During the period when it was important as a source of heat, the fireplace became the object of design work by significant artists. A Scottish architect, Robert Adam, and his brothers and an Italian architect and engraver, Giambattista Piranesi, made considerable artistic contributions to the design and construction of fireplaces.

Other accessory furnishings. Small utility objects constitute an important part of the furnishing of interiors. Several of them are the work of cabinetmakers; for example, boxes for writing paper and playing cards, caskets for letters and documents, trays for serving or presentation. Accessory furnishings include the various articles, large and small, that are employed in the course of domestic work—from small looms to lace pillows, spinning wheels, embroidery frames, and sewing tables. Women's chattels, partly in the form of equipment for domestic needs and partly in the form of items of storage furniture for such small items as pins, scissors, wool, and materials, all had their place in the home.

Finally, the structure and decoration of the walls, ceilings, and floors—for example, panelling, stucco work, parquet flooring, carpets—also come under the heading of accessory furnishings. (Er.L.)

History

WESTERN

Egypt. Beds, stools, throne chairs, and boxes were the chief forms of furniture in ancient Egypt. Although only a few important examples of actual furniture survive, stone carvings, fresco paintings, and models made as funerary offerings present rich documentary evidence. The bed may have been the earliest form; it was constructed of wood and consisted of a simple framework supported on four legs. A flax cord, plaited, was lashed to the sides of the framework. The cords were woven together from opposite sides of the framework to form a springy surface for the sleeper. In the 18th dynasty (*c.* 1567–1320 BC) beds sloped up toward the head, and a painted or carved wooden footboard prevented the sleeper from slipping down (Figure 62).

Construction of the Egyptian bed

The great beds found in the tomb of Tutankhamen were put together with bronze hooks and staples so that they could be dismantled or folded to facilitate storage and transportation; furniture existed in small quantities and when the pharaohs toured their lands, they took their beds with them. In the same tomb was a folding wooden bed with bronze hinges.

Figure 62: Reconstructed bed canopy with bed, chair, and curtain box from the tomb of Queen Hetepheres at Giza, wood overlaid with gold foil, Egypt, 4th dynasty, *c.* 2600 BC. A bed, with detachable footboard of inlaid faience and silvered headrest, and a low armchair stand beneath a canopy designed to take hangings. In the Museum of Fine Arts, Boston. Original in the Egyptian Museum.

Instead of pillows, wooden or ivory headrests were used. These were so essentially individual, being made to the measure of the owner, that they were often placed in tombs to be used by the dead man on his arrival in the land of eternity. Folding headrests were probably for the use of travellers.

Early stools for ceremonial purposes were merely squared blocks of stone. When made of wood, the stool had a flint seat (later shaped concavely) covered with a soft cushion. In time the stool developed into the chair by the addition of a back and arms. Such throne chairs were reserved for use by personages of great importance. Footstools were of wood. The royal footstool was painted with the figures of traditional enemies of Egypt so that the pharaoh might symbolically tread his enemies under his feet. Carvings of animal feet on straight chair legs were common, as were legs shaped like those of animals. Boxes, often elaborately painted, or baskets were used for keeping clothes or other objects. Tables were almost unknown; a pottery or wooden stand supporting a flat basketwork tray held dishes for a meal, and wooden stands held great pottery jars containing water, wine, or beer.

The Egyptians used thin veneers of wood glued together for coffin cases; this gave great durability. Egyptian furniture in general was light and easily transportable; its decoration was usually derived from religious symbols, and stylistic change was very slow.

Mesopotamia. The furniture of Mesopotamia and neighbouring ancient civilizations of the Middle East had beds, stools, chairs, and boxes as principal forms. Documentary evidence is provided chiefly by relief carvings. The forms were constructed in the same manner as Egyptian furniture except that members were heavier, curves were less frequent, and joints were more abrupt. Ornament was richly applied in the form of cast-bronze and carved-bone finials (crowning ornaments, usually foliated) and studs, many of which survive in museums. Mesopotamia originated three features that were to persist in classical furniture in Greece and Italy and thus were transmitted to other western civilizations. First was the decoration of furniture legs with sharply profiled metal rings, one above another, like many bracelets on an arm; this was the origin of the turned wooden legs so frequent in later styles. Second was the use of heavy fringes on furniture covers, blending the design of frame and cushion into one effect; this was much lightened by classical taste but was revived in Neoclassicism. Third was the typical furniture grouping that survived intact into the Dark Ages of Europe: the couch on which the main personage or personages reclined for eating or conversation; the small table to hold refreshments, which could be moved up to the couch; and the chair, on which sat an entertainer—wife, hetaera (courtesan), musician, or the like—who looked after the desires of the reclining superior personages. From this old hierarchy of furniture derive the cumbersome court regulations concerning who may sit and on what, persisting in the palaces and ceremonies of 20th-century monarchs.

Mesopotamian ornamentation

Greece. Principal furniture forms were couches, chairs (with and without arms), stools, tables, chests, and boxes. From extant examples, the depiction of furniture on vases and in relief carvings, and literary descriptions, much more is known about Greek furniture than about Egyptian. At Knossos, a built-in throne of stucco, much restored, is often considered to represent pre-Hellenic furniture in the Aegean area (Figure 17). Primitive Aegean pottery shows rounded chair forms, perhaps indicating basketry models, and Bronze Age sculpture shows complex-membered chair frames.

The Greek couch

In ancient Greek homes, the couch, used for reclining by day and as a bed by night, held an important place (Figure 63). The earliest couches probably resembled Egyptian beds in structure and possibly in style. The legs occasionally imitated those of animals with claw feet or hoofs, but usually they were either turned on the lathe and ornamented with moldings or cut from a flat slab of wood sharply silhouetted and decorated in various ways—with incised designs or with volutes, rosettes, and other patterns in high relief. From about the 6th century BC, the legs projected above the couch frame; these projections became headboards and footboards, the latter eventually made lower than the headboards. In Hellenistic times headrests and footrests were carved and decorated with bronze medallions carrying busts of children, satyrs, or heads of birds and animals in high relief. Turned legs largely replaced rectangular ones. Although a bronze bed of the 2nd century BC has been found at Priene and marble couches sometimes occur in tombs, the usual material was wood. The legs often terminated in metal feet and sometimes were encased in bronze moldings, and the rails also were sometimes covered with bronze sheathing.

Klismos and *diphros* chairs

From the Greek Archaic period onward many varieties of individual seats are known, the most imposing, perhaps, being elaborately adorned, high-backed ceremonial chairs of wood or marble. Like the couches, they were supported on turned legs, legs cut from a rectangular piece of wood, or legs with animal feet; they frequently had arm rails. Another type of boxlike seat with no feet and with or without a back is also found. The klismos chair was lighter and had a curved back and plain, sharply curved legs, indicating a great mastery of wood-working. The *diphros* was

Figure 63: Greek couch and rectangular table from an Attic amphora decorated by Andocides with scenes of Heracles dining, c. 510 BC. In the Staatliche Antikensammlungen und Glyptothek, Munich.

a stool standing on four crossed, turned legs, sometimes connected by stretcher bars and sometimes terminating in hoofs or claw feet. The convenience of folding stools was realized at an early date, and the *diphros* was popular.

Greek tables were usually small and easily portable. An interesting type had an oblong top supported by three legs, two at one end and one at the other. These legs usually tapered from the top and terminated in claw feet, and the bronze and stone examples which are occasionally found show carved flutings on the front of the legs and scroll ornament at the side below the table tops. Rectangular tables with four legs were also used, as were round tops.

Rome. Principal furniture forms were couches, chairs with and without arms, stools, tables, chests, and boxes. Excellent documentary evidence is found in mural paintings, relief carvings, and literary descriptions. Extant examples are more common than those of the ancient Near East: a wealth of bronze furniture was recovered at Pompeii; at Herculaneum even wood pieces were partly preserved.

The Roman couch

As in Greece, the couch was a principal furniture form. At Pompeii couches with bronze frames closely resembled Greek examples. Gold, silver, tortoiseshell, bone, and ivory were used for decoration, with veneer of rare woods. Later couches, found in Italy and in distant parts of the empire, were characterized by the high back and sides.

Roman chairs developed from Greek models. The Greek throne chair evolved into a small armchair with solid rounded back made in one piece with sides set on a rectangular or semicircular base. This armchair was often of wickerwork, wood, or stone. The Greek klismos chair was given heavier structural members by the Romans and was called the cathedra.

The Romans developed a decorative type of stool, often made in bronze. This was supported by four curved legs, ornamented with scrolls. The folding stool, with cross legs sometimes connected by stretcher bars, was used both by Roman officials and in households. Remains of folding stools are known from sites such as those at Ostia, Italy, and barrows in Britain—on the Essex-Cambridgeshire border, and in Kent. This developed into a stool that had more solid double curved legs; examples were found at Pompeii. An example in iron with bronze decorations, even heavier in form, was found at Nijmegen, in The Netherlands.

Roman tables

Tables with round and rectangular tops and three and four legs were common. Tables with round tops and three legs of animal form became increasingly popular from the 4th century BC onward (Figure 64). A nearly complete wooden table, found in Egypt and now in the Palais du Cinquantenaire, Brussels, is decorated with swans' heads with graceful necks rising out of a band of acanthus foliage, below which are very realistic antelope legs, with hoofs instead of claw feet. This type of table seems to have been popular throughout the Roman empire, as it often appears on tombstones depicting funerary banquets. It is known that citrus wood and Kimeridgian shale were favourite materials. Several complete tables found at Pompeii and Herculaneum, usually in gardens or open courts, are made of marble and decorated with beautifully carved heads of lions and panthers. Another type of smaller table is round or rectangular with only one central leg. Also found are pairs of solid slabs ornamented in high relief, carrying carved tops of marble or wood.

Pompeian wall paintings show that plain, undecorated wooden tables and benches were used in kitchens and workshops, and some household possessions were kept in cupboards with panelled doors. Rectangular footstools, sometimes with claw feet, were used with the high chairs and couches. Small bronze tripods and stands were also items of Roman furniture. Clothes and money were stored in large wooden chests with panelled sides, standing on square or claw feet. Roman treasure chests were covered with bronze plates or bound with iron and provided with strong locks. Jewelry and personal belongings were kept in caskets, in small round or square boxes, or even in baskets.

Storage chests

Middle Ages. *Early Middle Ages.* With the collapse of the Roman Empire during the 4th–5th centuries, Europe sank into a period in which little furniture, except the most basic, was used: chairs, stools, benches, and primitive chests were the most common items. Several centuries were to pass before the invading Teutonic peoples evolved forms of furniture that approached the Roman standard of domestic equipment.

Comparatively little furniture of the medieval period in Europe has survived, and only a handful of these pieces date from before the end of the 13th century. One reason for this is the perishable nature of wood, but more important is the fact that furniture was made in relatively small quantities until the Renaissance. Much of the earlier history of furniture has to be drawn from contemporary literature, illuminated manuscripts, Romanesque and Gothic sculpture, and later inventory descriptions.

There is evidence that certain ancient traditions of furniture making, particularly that of turnery, influenced early medieval craftsmen. Turnery was used in making chairs, stools, and couches in Byzantium, and it seems that this technique was known across Europe as far north as Scandinavia. The Anglo-Saxon epic poem *Beowulf,* which gives some glimpses of the domestic economy of western Europe in about the 7th century, mentions no furniture other than benches and some kind of seat or throne for the overlord.

Later Middle Ages. In the 14th and 15th centuries there were many developments both in construction and design of furniture throughout Europe; a range of new types, among them cupboards, boxes with compartments, and various sorts of desks, evolved slowly. Most of the furniture produced was such that it could be easily transported. A nobleman who owned more than one dwelling place usually had only one set of furnishings that he carried with him from house to house. Anything that could be moved, and this frequently included the locks on the doors and the window fittings, was carried away and used to furnish the next house en route. Furniture was so scarce that it was quite usual for a visitor to bring his own bed and other necessities with him. These conditions had a double effect on medieval furniture, not only making it difficult for men to possess more than the basic types of furniture but also affecting the design of the furniture itself. Folding chairs and stools, trestle tables with removable tops, and beds with collapsible frameworks were usual.

The need for easily transported furniture

The religious houses were an exception to this in that they enjoyed a certain security denied to the outside world. Much of the best furniture of this period was therefore made for use in churches and monasteries, and many of the ideas and developments that were later to add to the domestic comfort of Europe originated in the cloister. An

example can be seen in the early development for ecclesiastical use of the various types of reading and writing furniture, such as lecterns and desks, that show ingenuity in construction. Throughout the Middle Ages and well on into the 16th and 17th centuries, all types of furniture remained scarce, and any reasonably good furniture belonged to the nobility and the wealthy merchants. The household equipment of the peasantry throughout Europe, even as late as the 18th century, was frequently crude in design and roughly constructed.

Framed panelling

Framed panelling had been used in ancient times, as examples found at Herculaneum testify; its reintroduction in the Burgundian Netherlands at the beginning of the 15th century was an improvement that soon spread throughout western Europe. Panelled construction solved the problem of building large surface areas, as on the front of a chest or cupboard, which before this time had been limited by the size of individual planks. These planks, usually hewn with an adz, were heavy and liable to warp and split. Panels could be cut thinner, the main strain being taken by the framework, and the furniture was therefore lighter; moreover, if the panels were not fitted too tightly in their stiles, the wood was less likely to split if it did warp. Now that it was possible to construct larger surface areas, a new range of storage furniture, cupboards and chests in particular, was developed.

Other constructional improvements of the 15th century included the introduction of drawers into cupboards and similar storage furniture, and neater and more efficient joints, such as the mitre and the mortise and tenon. Panelling was frequently decorated with a flat form of ornament called linenfold, or parchment. Linenfold was widely used in the north of France, Flanders, Low Germany north to the Baltic, Scandinavia, and England. The linenfold of France, the Low Countries, and Germany is carved with a sharper definition and greater delicacy than was usual in England and elsewhere. Both panelled furniture and room panelling were decorated with linenfold. Other forms of carved decoration on furniture became more common during the 15th century, when surfaces were carved with tracery and other Gothic motifs. During the Middle Ages a great many pieces of furniture, including those with carved decoration, were painted and sometimes gilded, a practice that continued well on into the Renaissance (the present state of existing pieces, with their plain wooden surfaces, is misleading). Chairs, tables, and various types of cupboards were also frequently draped with bright fabrics, while chairs, settles, and other seat furniture were provided with cushions.

The medieval chest

The chest was the basic type of medieval furniture, serving as cupboard, trunk, seat, and, if necessary, as a simple form of table and desk. It was from this versatile piece of furniture that several other types, such as the cupboard and the box chair, were evolved. Chests were made of six planks, crudely pegged or nailed together and frequently strengthened with iron banding. Examples of this sort, dating from the 13th century and in many instances found in churches, are among the earliest pieces of extant European furniture. The chest remained one of the most important pieces of furniture until the end of the 15th century, when on the Continent the cupboard began to compete with it in usefulness.

Chairs remained scarce throughout the Middle Ages, and occupation of a chair long symbolized authority or a mark of honour, and even a large house might possess only chairs for the lord and his wife and perhaps another for a distinguished visitor; the use of the word chairman is a modern reflection of this medieval custom. Early chairs constructed of turned spindles, seen in Romanesque sculpture, have already been mentioned. Later there were two main types. One was a variety of folding chair, with X-shaped frame, made of both wood and metal, the seat and back consisting of rectangular strips of some strong fabric or leather (Figure 65). Eventually there evolved a heavier type of chair. This was basically a development of the chest, and in many cases the seat was hinged, allowing the base to be used for storage. Panelling, often carved with linenfold and sometimes with other Gothic motifs, was used on the back, arms, and base. Many of these chairs had exaggeratedly high backs terminating in elaborately carved canopies; some were freestanding, while others had their backs fixed to the wall in the manner of a church stall. Settles were also used for seating during the 15th century. An innovation on the Continent was the settle with a pivoted bar forming the backrest, which could be swung over to allow a person to sit on either side—evidence of the weight of the furniture of this period.

Tables

Tables were mainly of trestle construction (with a braced frame serving as a support for the tabletop) with long rectangular tops that could be dismantled. During the 15th century on the Continent, smaller tables were made which could be more conveniently moved and, especially, drawn up to the fire. Various forms of cupboards, ambries, and dressoirs were developed at this time, panelled and decorated with linenfold or Gothic carved ornament. All these types were basically a chest with doors, of simple rectangular form raised on legs; elaborations of construction and decoration soon followed, as did the specialization of their functions. Cupboards, dressoirs, and credence (sideboard or buffet) tables were used for the storing of plate and for serving at banquets, the plate being displayed on the top and on shelves above and below the main serving surface. Top shelves were sometimes cantilevered or projected on brackets to free the front corners of this surface for use. Other cupboards were made to hold food and day-to-day provisions; in the case of food, or dole cupboards as they were called, the front and sides were pierced for ventilation.

Medieval beds are known from documents and a few late examples. Recalling Egyptian beds, throughout most of this period a diagonal surface, lifting the head high, was common. Some beds had daringly cantilevered ceilings supported from the headboards.

Figure 65: Massive limestone mantelpiece from Alençon and chairs with X-shaped frames, France, 15th century In the Metropolitan Museum of Art, New York, The Cloisters Collection

English furniture

Little English furniture survives from medieval times, and, as on the Continent, information must be sought in contemporary references and from the picture of domestic interiors in illustrated manuscripts. Most of these manuscripts are of French or Flemish origin, but they furnish reliable evidence on English interiors because the governing classes, who were practically the sole possessors of proper furniture, copied the domestic habits of the Continent. English oak was the chief material, but softer woods also were used. A certain amount of furniture was imported from abroad, providing new ideas for the English carpenter and joiner. The furniture usually found in important houses consisted of beds, chests, cupboards, tables, benches, and stools.

The Renaissance. *Italy.* From the beginning of the Renaissance in the early 15th century, there were changes in furniture forms that were to spread over Europe. The growth of a wealthy and powerful bourgeoisie caused the building of more substantial houses and a demand for good furniture. Italian Renaissance furniture shows a strong architectural bias, and the purpose of the piece, as in Roman furniture, was subordinate to its form. The furniture of the early Italian Renaissance is often restrained, with beautiful, simple designs carved in walnut (Figure 66). For more elaborate work, sculpture in low relief and stucco modelled in intricate patterns were much used. The stucco was usually gilded all over and picked out in bright colours.

The cassone, or marriage coffer (hope chest), was a form on which the craftsman's skill was lavished. In addition to elaborate relief work and gilding, these coffers often were painted on the front and sides and occasionally inside the lid as well, with appropriate biblical or mythological scenes. Motifs popular with the Italian carver included cupids, grotesque masks, scrolled foliage, and strapwork. The fixed writing desk is the forerunner of the writing bureau, which became an indispensable article of furniture as writing became more general.

Renaissance chairs

A type of chair called a sgabello was much favoured at this time in Italy. The seat was a small wooden slab, generally octagonal, supported at front and back by solid boards cut into an ornamental shape; an earlier variety was supported by two legs at the front and one in the rear; a solid piece of wood formed the back (Figure 24). Another chair of the period was the folding X-shaped chair, sometimes called a Dante chair. Tables were generally oblong, supported by columns, consoles (brackets), or terminal figures, with a long central stretcher running from end to end. Italian Renaissance furniture forms reshaped the furniture of the remainder of Europe.

France. The furniture of France was among the first to be influenced by the Italian Renaissance. Louis XII and many of his court visited Italy and soon took Italian artists and craftsmen and works of art into France. The French Renaissance of furniture can be divided into two stages. First was a period of transition and adaptation; during the reign of Louis XII and the first part of the reign of Francis I, the pieces were basically Gothic in form, and Gothic ornament was mixed with the cupids, medallion heads, and grotesque decorations of the incoming Renaissance style. During the second phase, from the end of the reign of Francis I, the new style displaced the Gothic. The more exuberant arabesque shapes of Renaissance decoration, however, gave way to increasingly architectural design, and oak was almost entirely superseded by walnut. Centres of furniture making were established at Fontainebleau, where Francis I employed several Italian artists and craftsmen; in Île-de-France, headed by the work of Jacques du Cerceau; and in Burgundy, where, led by the craftsman and designer Hugues Sambin, design was influenced by the Renaissance style evolved in the Netherlands.

16th-century French furniture

French furniture of the 16th century was remarkably graceful and delicate; it was enriched with inlay of small plaques of figured marble and semiprecious stones, sometimes with inlay or marquetry of ivory, mother-of-pearl, and different coloured woods.

Chairs began to be lighter in design; the back became narrower, the panelled sides and base were replaced by carved and turned arms and supports, and legs were joined by stretchers at their base. A specialized chair known as a caquetoire, or conversation chair, supposedly designed for ladies to sit and gossip in, had a high, narrow back and curved arms.

Elaborately carved oblong tables were supported by consoles or fluted columns connected by a stretcher surmounted by an arched colonnade. Chests decorated in the new style were still widely used, although frequently replaced by the armoire (a tall cupboard or wardrobe), which was sometimes made in two stages, the upper compartment containing numerous small drawers.

Spain. Because of the long occupation of Spain by the Moors, a style called Mudéjar evolved. While furniture in

SCALA—Art Resource

Figure 66: Renaissance furniture from the Sala dei Pappagalli in the Palazzo Davanzati, Florence, 15th and 16th centuries.

The vargueno cabinet

this style remained in form essentially European, decoration had an oriental flavour. A type of cabinet known as vargueno was typically Spanish. The upper part, in chest form, with drawers inside, had a fall front (a hinged writing surface that opened by falling forward), often elaborately mounted in wrought iron and backed by velvet, with a massive iron lock. The cabinets were richly carved, painted, gilded, and inlaid with ivory in a Moorish manner. There was a tendency for Italian models to be followed in the furniture of the 16th and 17th centuries.

Low Countries. In the 16th century, Italian Renaissance ornament was adopted and transformed by artists and designers of northern Europe, particularly in northern Germany and the Low Countries, who created an independent style of decoration. Strapwork, cartouches, and grotesque masks are characteristic features of this northern Renaissance style, and are found repeatedly in the pattern books of German and Flemish artists of the time—books of ornament which circulated among and influenced metalworkers, carvers, plasterers and furniture makers throughout the north.

Heavy oak tables, sometimes draw (extension) tables, had massive legs and solid stretchers. Beds were heavily draped to provide privacy, as the bed might be located in any room of the house. Folding wooden chairs and low stools, with more or less elaborate turnery, were still used, besides a new type with baluster-formed or twisted legs and arms, and straight backs heightening through the 17th century.

England. The Italian Renaissance did not affect the design or ornament of furniture in England until about 1520. Evolution from the Gothic style was a gradual process, influence coming first from Italy and, in the second half of the 16th century, from the Low Countries. In the early stages, furniture remained Gothic in form, though Italian motifs slowly replaced the older Gothic ornament. Many pieces of early Renaissance English furniture combined linenfold panelling with medallion heads and Italianate cupids, but by the middle of the century both new ornament and new forms had replaced the medieval style. About the middle of the century the direct influence of Italy weakened, and its place was taken by that of the Low Countries. The northern style of Renaissance ornament was propagated in England by pattern books, immigrant workmen, and imported Flemish and German furniture, and before long it was adapted by English craftsmen into an individual and peculiarly English style.

Characteristic of this style is the enrichment of every surface with flamboyant carved, turned, inlaid, and painted decoration, which strongly reflects the spirit of the English Renaissance. During Elizabeth I's reign there was a considerable and fairly widespread increase in domestic comfort, to be seen in improved construction, multiplication of types, and the tentative beginnings of upholstered furniture. A series of inlaid chests with perspective architectural scenes, often called nonesuch chests, were either imported from Germany or made by German workmen in England. They were influential in propagating the technique of inlaid decoration, which by the end of the century was being applied to every type of furniture.

Styles of the reign of Elizabeth I

Apart from the gradual change from Gothic to Renaissance ornament, the 16th century produced several changes in the design and construction of individual types. Chairs became slightly more common, though even in Elizabeth's own palaces, stools were the usual form of seating. From the box chair evolved a type in which the arms and legs were no longer filled in with panelling but which had plain or turned legs, with shaped arms resting on carved or turned supports. The backs of chairs were still panelled and decorated with carving and inlay or surmounted with a wide and richly carved cresting. Folding chairs, X-shaped and of varying construction, were also used. Chairs without arms, called farthingale chairs, were introduced in the early 17th century to accommodate the wide skirts, called farthingales, that were popular at the time. Farthingale chairs had upholstered seats and a low, rectangular upholstered back raised on short supports a little above the seat. Armchairs of similar design were made. Turkey work (a type of needlework) and velvet were usually employed for upholstery.

Early in the 16th century a new style of bed design appeared; the greater part of the frame was left exposed and was enriched with carving and other decoration, making the frame itself an important part of the design. Favourite carvers' motifs for beds and other types of furniture included strapwork, grotesque masks, and caryatids (draped female figures), bulbous turned pillars and supports, arcading (decorating consisting of arches or arcades), and patterns of scrolled foliage. The heavily turned "cup and cover" motif is frequently found on bedposts in the later 16th century. The cumbersome Gothic trestle tables were replaced by "joyned tables," with tops fixed to the frames. Draw tables, which could be conveniently lengthened by pulling out the two leaves concealed under the top, were also introduced. Table legs and sides were decorated with carving and inlay, and the cup and cover motif is often found on the legs. Various types of cupboards were made, usually in two stages, or levels. In court cupboards both stages were left open. A simple form of chest of drawers was introduced about 1620.

17th century: the Baroque style. During the 17th century, the Baroque style had a marked effect upon furniture design throughout western Europe. Large wardrobes, cupboards, and cabinets had twisted columns, broken pediments, and heavy moldings. In Baroque furniture the details are related to the whole; instead of a framework of unrelated surfaces, each detail contributes to the harmonious movement of the overall design. The Baroque style was adopted in the Low Countries in the 1620s and extended late into the 17th century, when Germany and England began to develop it. It owed much to the Oriental influence that swept over Europe in the 17th century, when several maritime countries, particularly Portugal, Holland, and England, established regular trading relations with India and the Far East. Lacquered furniture and domestic goods were imported from the East, where Oriental craftsmen also worked in a pseudo-European style from designs supplied by the traders. Before the end of the 17th century, Oriental decorative techniques were being widely imitated in Europe, and the roots of the "Chinese taste" were firmly entrenched. Heavy tropical woods were also brought to Europe, and from these, furniture was made that borrowed much from the prevailing taste for Oriental elaboration.

Influence of Oriental decorative techniques

Flanders and Holland. The early Flemish Baroque fur-

niture, dating from the second quarter of the 17th century, was but a slight adaptation of the late Renaissance style. Typical are the oak cupboards with four doors and the chairs with seats and backs of velvet or leather held in place by nails.

In Holland the Baroque style did not encroach on late Renaissance furniture until nearly 1640. Dutch furniture of this period can be distinguished by its simpler design and a preference for molded panels over carved ornament. Later, marquetry decoration and walnut-veneer surfaces became the most common decorative treatments. At the end of the century lacquered furniture became popular.

Italy. Though it was in Italian architecture, painting, and sculpture that the Baroque style was evolved, Italy was not the first to apply this style to furniture. But by the mid-17th century Italy was producing flamboyantly carved, painted, and gilded furniture, decorated with such typical motifs as cupids, acanthus, shells, and boldly drawn scrolls (Figure 67), and was further enriching chairs and stools with fine-cut velvets and table tops with marble or *pietra dura* (a mosaic-like technique in which coloured stones are cut and shaped and inlaid in a design). Chairs and stools with exaggerated scrolled arms and legs, and handsome walnut and ebony cabinets and cupboards with carved decoration on the pediments, friezes, and corners and sometimes inlaid with marble or *pietra dura* set in molded panels, typify the Italian furniture of the later Baroque phase (Figure 68).

France. In France the Italian influence of the 16th century was gradually assimilated, and a national style of furniture was evolved that soon spread its influence into neighbouring countries. The reign of Louis XIII, covering most of the first half of the 17th century, was a time of transition. The Gobelins factory was founded by Louis XIV for the production of deluxe furniture and furnishings for the royal palaces and the national buildings. The painter Charles Le Brun was appointed the director in 1663. Furniture was veneered with tortoiseshell or foreign woods, inlaid with brass, pewter and ivory, or heavily gilded all over. At times it was even completely overlaid with repoussé (formed in relief) silver. The name of André-Charles Boulle is particularly associated with this style of decoration. His cabinets and tables were completely covered by sheets of tortoiseshell and brass cut into intricate patterns so as to fit into one another, the tortoiseshell alternately forming the pattern and the ground: hence the two types, boulle (buhl) and counterboulle. The light, fanciful designs of the architect and designer Jean Berain were much used for this work. Heavy gilt bronze mounts protected the corners and other parts from friction and rough handling, and provided further ornament.

Gobelins factory

England. After the Restoration, from 1660 onward, there was almost revolutionary progress in English cabinetmaking, as it came to be called at about this time. On its return, the exiled court introduced French and Dutch fashions, and the English craftsmen were considerably helped in supplying the tastes of the nobility by a large influx of foreign workmen. Furniture became lighter, more highly finished, and better adapted to varying needs. The general increase in technical skill of the cabinetmaker between 1660 and about 1690 is astonishing. Walnut was the favourite wood, though the use of oak continued in the country districts for many generations. New processes appeared, notably veneering wide surfaces with thin sheets of wood into which floral patterns in marquetry often were inserted. In the earlier period of the Restoration these patterns were large, but toward the end of the century they grew smaller and more intricate, leading eventually to the type of marquetry made up of numerous small scrolls and called seaweed marquetry.

The passion for colour found an outlet in lacquer decoration in England as in other European countries. The importation of works of art from the East had begun in Tudor times but was of little account until after the Restoration, when the taste became widespread. The diarist John Evelyn and others reported their friends' houses to be furnished with Indian screens or panelled in the finest "japan" (the process that imitated Oriental lacquery was called "japanning" in England).

New forms of furniture in the 17th century

New forms of furniture began to develop: the daybed, a form of couch with an adjustable end; the winged armchairs; the upholstered armchair called in the 17th century a sleeping chair; and, a little later, toward the end of the century, sofas with backs and arms carried comfort a step further. Velvet, silks, and needlework were the usual materials for upholstery. Various kinds of writing furniture were rapidly developed, including toward the end of the century, the bureau with enclosed desk and interior fittings of small drawers and pigeonholes.

Chests of drawers came into more general use. Mirrors were no longer rarities, though glass remained expensive. The frames were carved, lacquered, or decorated with marquetry. Fashions succeeded each other with great rapidity. Chairs show these changes most clearly, developing in a brief period from mere seats of Charles II, while, later, straight tapering baluster forms were used. In the grander beds of this period, the tester (canopy), back, and posts were covered with material. The beds were of enormous height with elaborately molded cornices and had ostrich plumes or vase-shaped finials at the corners of the tester. These state beds were strongly influenced by the designs of the French architect Daniel Marot, who went from France to England to work for William and Mary.

During the late 17th century and on into the first half of the 18th century, a certain amount of elaborately carved and gilded furniture, much influenced by the style of Louis XIV, was produced in England (Figure 69). Foremost among the makers of this deluxe furniture were three cabinetmakers: John Pelletier, Gerrit Jensen, and James Moore. Toward the end of the 17th century, during the reign of William and Mary, Baroque furniture tended to become simpler and the use of ornament was somewhat restrained. At the beginning of the 18th century, during

Queen Anne style

Figure 69: Late Stuart style dining room, Belton House (1685–89), near Grantham, Lincolnshire, England.
Edwin Smith

the reign of Queen Anne, a new and simpler style arose, much influenced by the contemporary furniture of Holland. Carving and applied ornament were reduced to a minimum and the beauty of a piece was made to rely on carefully designed curved lines and the colour of fine walnut veneers. The cabriole leg, originally devised in classical times and based on the curve of an animal's leg, was introduced into England from the Continent about 1700. Terminating in a claw-and-ball or paw foot and soon discarding the stretcher, it was widely used on chairs and tables and for every kind of support. The stretcher had become obsolete because of improved joining and gluing. Chairs had hooped uprights, and fiddle-shaped splate curved to support the back. Tallboys, or double chests of drawers, cabinets fitted with shelves, and bureaus in two stages met the demand for greater convenience, as did a new range of dining, card, and other tables.

The American colonies. As in all colonial settlements, the furniture of the American colonies reflected the style preferences of the individual national groups. This influence, coupled with the existence of new materials and the time lag in transmitting styles and tastes from the home country, in some instances produced highly individual furniture.

Information in inventories and wills about 17th-century furniture of the English colonies indicates that it existed in its simplest forms—stools, benches, tables, cupboards, and a few chairs (Figure 38). This furniture, often made of oak, recalled the tradition of Elizabethan England and was turned and decorated with chip carving, often picked-out in earth colours. By the end of the century, pine, maple, and other woods were used.

The Dutch and Scandinavian settlers carried with them individual furniture forms whose influence remained local.

By 1700 the effect of French and Dutch fashions on late Stuart furniture in England had become evident in the American colonies. Fashion consciousness appeared, though for decades to come the furniture of the average colonial home kept to the earlier tradition evolved from medieval joining. The box chest was succeeded by the chest of drawers, often placed on a stand with turned legs. Chairs began to replace stools; and the early heavy, turned, and wainscot (panelled back) types gave way to simplified versions of the high-back scrolled forms of the English Restoration fashion. The daybed appeared with its upholstered pad. Small folding tables, cabinets, and the tiered dresser to store and display tableware testify to the rapidly increasing standard of comfort among the more prosperous. Carved surface decoration was largely replaced by colour, through the use of paint, veneers, or inlays of contrasting wood.

Awakening of fashion consciousness

These innovations accompanied the use of the cabriole, or reverse curve, which, about 1725, became the favoured form for legs of chairs, tables, cabinets, and stands. At first it had little or no carving and a simple paw foot, but the design was elaborated, and this cabriole leg became the principal feature of the so-called Queen Anne style that dominated colonial furniture designs until the Revolution. Walnut became the principal wood of the early 18th century.

18th century: the Rococo style. The influence of French furniture was predominant in Europe during the 18th century. In the second half of the century England played a leading role in establishing the Neoclassical style, and for supreme craftsmanship provided an inspiration to workshops in several countries; but in the diffusion of the two styles, the Rococo and the Neoclassical, French designs were universally imitated, with varying degrees of success.

Influence of French furniture

France. The transitional phase in French furniture from Baroque to Rococo is called Régence. The heavy, monumental style of the earlier part of Louis's reign was gradually replaced by a lighter and more fluent curvilinear style. The leading exponent of the Régence style was Charles Cressent, *ébéniste* ("cabinetmaker") to the regent Philippe II, duc d'Orléans. In his work the ormolu (a brass imitation of gold) mounts, so important a part of the design of French furniture in the 18th century, became equal to if not more important than, the marquetry decoration of the carcass. The curvilinear form was introduced not only to externals, such as legs and supports, but, in the bombé (rounded sides and front) commodes that first appeared during this period, to the case itself. High-quality marquetry in coloured woods replaced ebony.

The Rococo style, a development of the Régence, affected French furniture design from about 1735 to 1765. The word is derived from rocailles, used to designate the artificial grottoes and fantastic arrangements of rocks in the garden of Versailles; the shell was one of the basic forms of Rococo ornament. The style was based on asymmetrical design, light and full of movement. The furniture of this period was designed on sinuous and complicated lines. Designs of Juste Meissonier, goldsmith to Louis XV, sculptor and architect, were instrumental in creating the Rococo. The repertory of ornament was large and included the C-scroll, scrolled foliage, floral motifs, ribbon, and, on occasion, trophies formed of musical instruments or gardening implements. The Rococo Chinese taste had conventions of its own: pagodas, exotic birds, Chinese figures, icicles, and dripping water. The graceful bombé commode, often with marble top and two or three drawers, the surface enriched with finely modelled ormolu mounts, was popular. Under Cressent's influence the mounts predominated, though later in the century the marquetry decoration gained first importance. Commodes and other pieces were decorated with marquetry of floral or geometrical patterns, or sometimes with lacquer decoration, again combined with ormolu mounts. The most celebrated makers of mounts during Louis XV's reign were Jacques Caffieri and his son Philippe. Jean-François Oeben was made *ébéniste du roi* (cabinetmaker to the king) in 1754; a pupil of Boulle, he was the most celebrated cabinetmaker of the period (Figure 70).

Characteristics of the Rococo style

England. About 1720, mahogany was imported into England and slowly superseded walnut as the fashionable wood for furniture. The Palladian (after the Italian Renaissance architect Andrea Palladio) interiors demanded

Figure 70: Rococo writing desk, the *bureau du roi,* with intricate pictorial marquetry and elaborate ormolu mounts made for Louis XV, begun by Jean-François Oeben in 1760 and completed by Jean-Henri Riesner, 1769. In Versailles.
Giraudon

furniture more striking and larger in scale than the walnut-veneered pieces of the early 18th century. Inspired by the interiors of French and Italian palaces, architects such as William Kent began to design furniture. The design was classical, in keeping with the traditions of Palladio and the English architect Inigo Jones; the ornament was Baroque. At Holkham Hall in Norfolk, Rousham Hall in Oxfordshire, and elsewhere, Kent's furniture may be seen in its proper environment: gilt mirrors and side tables with sets of chairs and settees covered with patterned velvets matching the grandeur of elaborate architectural Palladian interior decoration.

Despite the resistance of the Palladian classicists who deplored its asymmetrical principles, in the 1740s the Rococo style crept into English decoration and furniture design. During this decade pattern books of ornament in the full Rococo style by Matthias Lock and Henry Copland were published in London; and in 1754 Thomas Chippendale published his *Gentleman and Cabinet Maker's Director,* which provided patterns for a wide range of English furniture in the Rococo style and its Chinese and Gothic offshoots. During the following years several similar works were published by such craftsmen and designers as William Ince and Thomas Mayhew, Thomas Johnson, and Robert Manwaring. The Rococo style was firmly established in England throughout the 1750s and into the 1760s. Chippendale and other cabinetmakers borrowed not only ornament from the French rocaille but designs for individual types. Chippendale's fame rests largely on his publication, though in fact it has now been more or less conclusively proved that he himself was not responsible for the designs, but employed two other designers, Lock and Copland. There were several cabinetmakers—for example, William Vile and John Cobb—whose only memorial is a small quantity of furniture attributable to them. Though it has become the practice to speak of a Chippendale chair or a Vile commode, this does not imply that the pieces were actually made by these craftsmen but that they were made in their workshops.

The work of Thomas Chippendale

By mid-18th century every act of the day that necessitated the use of furniture was catered to by some specialized piece, while the basic furniture such as chairs, cupboards, beds, and tables were designed and decorated in innumerable forms. The number of variants on the Rococo chair splat runs into several hundreds. The ingenuity of the cabinetmaker and carver knew few limitations.

An offshoot of the Rococo style, the Gothic taste was particularly well developed in England. Starting early in the century as a literary device, in the 1740s it began to take more solid shape in architecture, interior decoration, and furniture. As with furniture in the Chinese taste, Gothic furniture bore no relation to its medieval equivalents; the ornaments, such as tracery and cusped (a point formed by the intersection of two arcs or foils) arches, applied to furniture were borrowed from Gothic architecture. The Gothic taste was much publicized by the writer Horace Walpole's celebrated villa, Strawberry Hill, in Middlesex, England. Chippendale included designs for furniture in the Gothic taste in all three editions of his *Director.*

The Gothic taste

The American colonies. Shortly after 1750 the earlier cabriole style was transformed by two factors. One was the rapidly increasing popularity of mahogany. The other was the influence of the English version of free Rococo ornament, as reflected in the publication of Chippendale's book of patterns.

While the Southern planter still depended largely upon London for his fine furnishings, the merchants of Philadelphia, New York, Newport, and Boston were well rewarded by their patronage of local craftsmen. In Philadelphia a local version of the Chippendale style was brought to the highest mastery by such craftsmen as Thomas Affleck, Jonathan Gostelowe, Benjamin Randolph, and William Savery. In Newport, Rhode Island, the genius of the John Goddard and John Townsend cabinetmaking families evolved an equally distinctive style by developing a block front decorated by the patterns of the wood grains instead of carving, as used by their contemporaries in Philadelphia. In spite of the Philadelphians' evident desire to match the works of the best London shops, they actually created their own style as distinct from that of England as the innovations of their Newport colleagues (Figure 39). The cabinetmakers of Boston, New York, and the Connecticut valley also produced work of high quality and a definitely local flavour. Maintaining its hold on popular taste until well after the Revolution, this colonial Chippendale retained more of the sturdy elegance of the earlier cabriole style than did its English equivalent. The tendency of English design to massiveness and surface decoration contrasts with the vertical and linear tendency in much colonial design.

Colonial Chippendale

18th century: the Neoclassical style. *France.* The Neoclassical style, sometimes called Louis Seize, or Louis XVI, began in the 1750s. Tiring of the Rococo style, craftsmen of the 18th century turned for inspiration to classical art. The movement was stimulated by archaeological discoveries, by travel in Italy, Greece, and the Near East, and by the publication, all over Europe, of works on the classical monuments. The Neoclassical style, based on straight lines and rectilinear forms and using a selection of classical ornaments, was first applied to French furniture during the 1760s. Classical motifs at first were sparingly applied to furniture of unchanged form, but slowly the curved line of rococo was replaced by a simpler and more severe rectilinear design: chair legs became straight, tapered, and fluted; commodes and other storage furniture were no longer of bombé form. Marquetry was still widely used for decoration, and some cabinets were made of ebony inset with panels of Japanese lacquer. Boulle, which had not been employed in Louis XV's reign, returned to fashion. A greater number of pieces were signed during this period (signing had been made compulsory in Paris), and Jean-Henri Riesener, Martin Carlin, and Jean Saunier were a few of the leading cabinetmakers. Several German craftsmen migrated to France because of the royal patronage, among them Abraham and David Roentgen, Adam Weisweiler, and Guillaume Beneman.

These craftsmen were often directly under the patronage of the king, having their workshops in the cellars of the Louvre. Within the shop there was a division of labour, with one craftsman specializing in furniture construction, another in lacquering, and so forth. The craftsmen and the shop were licensed by the government.

England. The classical reaction, which set in shortly after 1760, reimposed a classical discipline on design, though of a lighter and more delicate touch than that of the previ-

ous classicists, the Palladians. Robert Adam, whose name is inseparably associated with this movement, had, like earlier architects, studied in Italy. There he sought inspiration in the monuments of both classical times and the Renaissance. When given a free hand, he included interior decoration and furniture in his architectural schemes, one of the best examples being his alterations and redecorations at Osterley, Middlesex, where he provided harmonious designs for even the lock plates and chimney pieces. His furniture makes restrained use of classical ornament; but paterae (disks with a design in relief or intaglio), husks (a drop ornament made of whorls of conventionalized foliage usually in a diminishing series), rams' heads, and urns are less eloquent of the change than the symmetrical structural lines. Marquetry, ormolu mounts, and painting were employed as decoration (Figures 37, 71). Adam's furniture was copied and modified by contemporary cabinetmakers such as George Hepplewhite in his *Cabinet-Maker and Upholsterer's Guide* (1788).

In the last 20 years of the 18th century there was a tendency toward greater refinement, lightness, and delicacy in furniture design. Symmetry of form and excellence of proportion were retained for the most part. Heart- and shield-shaped backs on chairs and settees and tapered and fluted supports for tables and other pieces are characteristic; feathers, wheat ears, and shells are prominent in the painted or inlaid decoration. This refinement, strongly feminine in character, is represented in Thomas Sheraton's *Cabinet-Maker and Upholsterers' Drawing Book* (1791).

The work of Thomas Sheraton

The United States. The new classicism of Robert and James Adam came into vogue in the new republic during the last years of the century (Figure 43). The shipowners and merchants of Salem, Boston, and New York equipped their mansions with the work of Samuel McIntire, John Seymour, and Duncan Phyfe, each of whom produced individual interpretations of the Hepplewhite-Sheraton mode. This early Federal style is characterized by small-scale rectangular design and by a preference for light-toned wood finishes. Surfaces are generally unbroken but decorated with bandings and inlays of contrasting woods, or in Phyfe's case with low relief carvings in the Adam manner. The most typical pieces are the sideboard (a piece of dining room furniture with compartments and shelves for dishes) and the small secretary desk, both of which developed a peculiarly American form.

19th century. The Empire style began in Paris about the time of the Revolution and quickly spread throughout Europe, each country adapting it to its own national taste. In England it is commonly called the Regency style. Two French architects, Charles Percier and Pierre Fontaine, who designed the furnishings for the staterooms of Napoleon, contributed in great measure to the creation of the style. Their ideas were incorporated and propagated in *Recueil de décorations intérieures* (1801 and 1812; "Collection of Interior Decoration").

Basically the new style was a continuation of the Neoclassical style, with a much stronger archaeological bias, leading to direct copying of classical types of furniture; to this was added a new repertory of Egyptian ornament, stimulated by Napoleon's campaigns in Egypt. Mahogany-veneered furniture with ormolu mounts assumed the shapes of Roman, Greek, and Egyptian chairs and tables, with winged-lion supports and pilasters headed with sphinxes' busts or palm leaves; where no classical prototypes existed, contemporary designs were enlivened with classical ornament.

Characteristics of the Empire style

In England, Thomas Hope, an amateur designer with some knowledge of antiquities, was the chief exponent of the Regency style and entirely decorated his country house, Deepdene, Surrey, in it. When the fashion was taken up by cabinetmakers, the results were often woefully incongruous. Mahogany and rosewood were used with bronzed or gilt ornament, and metal inlay, a cheaper technique, replaced inlay and marquetry. Along with this style came a renewed enthusiasm for the Chinese taste, as best exemplified in the furniture and decoration of the Brighton Pavilion (Figure 41). In the final stages of the Regency style, both the design and construction of furniture in England and on the Continent showed signs of heaviness and overelaboration that heralded the general decline throughout Europe in the 19th century.

In the United States the style was widely adopted. Its chief native practitioner was the New York cabinetmaker Duncan Phyfe, who in the first decade of the century produced furniture for the wealthy of his city. His designs gave a unique interpretation to Empire ideas (Figure 72). French cabinetmakers, such as Charles-Honoré Lannuier, emigrated to the United States at this time and produced furniture in a stricter French style.

The work of Duncan Phyfe

By the 19th century, with increases in the efficiency of transportation and communication, styles became more

universal in their adoption but still maintained national and regional differences.

The Empire style, which carried over into the 19th century, began a series of styles that revived form and decoration from the past. This reinterpretation often resulted in a product removed from the principles of the original style. The introduction of the machine and of the factory method sometimes brought about a decline in quality in furniture production.

Biedermeier style

The Biedermeier style, which originated in Germany and Austria, flourished in the prosperous middle class homes of Europe from about 1815 to 1848. This style is characterized by classical simplicity. Chairs had curved legs, and sofas had rolled arms and generous upholstery. Mahogany veneers and light birch, grained ash, pear, and cherry were used. The design and much of the ornament were influenced by the Empire style, in particular the Grecian element. The style took its name from "Papa Biedermeier," a fictitious character whose column, offering opinions on taste in furniture, appeared in Austrian newspapers.

In the 1820s there was a revival of the Gothic style, which in England was partly stimulated by romantic literature such as the novels of Sir Walter Scott. Losing all the lightness and humour of the mid-18th-century Gothic revival, heavy medieval motifs were profusely and indiscriminately applied to every type of furniture.

A series of other revival styles followed the Gothic. The Rococo revival was one of the most popular; it borrowed the curvilinear elements of the French Louis XV style, especially the cabriole leg, and restated them in a heavier idiom. Entire suites of this furniture were fashioned in mahogany, rosewood, and walnut, the price being highly dependent upon the amount of carving on the frame.

During the first half of the 19th century (the exact date is unknown), metal springs were introduced into furniture construction. The spring construction made chairs and sofas much more comfortable than had the stuffing employed by cabinetmakers during the 18th century.

Another technical improvement introduced into furniture design was the use of plywood. Plywood had great strength and stability and could be more intricately curved than a natural piece of wood. One of the chief exponents of this technique in the United States was John Henry Belter, who was born in Germany in 1804 and served his cabinetmaker's apprenticeship in Württemberg. He reached a height of popularity in the 1850s. Belter's work is mainly in the Louis XV revival style.

Michael Thonet, an Austrian craftsman, experimented with bending layers of veneer in Boppard, Germany. Thonet was successful in perfecting a process for bending solid beechwood by heat into curvilinear shapes. His chairs, popular during the latter half of the 19th century, are still made.

Elizabethan and Louis XIV revival furniture was also very popular. The Baroque twisted upright was one of the chief elements employed. The straight, turned leg was also reintroduced. This elaborately upholstered furniture was produced in suites and was blocky and square in its overall form, in contrast to the Rococo revival form.

The Louis XVI style was reintroduced in suites of furniture with round tapering legs, oval backs on chairs and sofas, and elaborate upholstery. The Louis XVI leg was often used on comfortable upholstered furniture whose structure consisted primarily of a flexible metal, or "Turkish," frame. The only wood visible on this furniture was in the legs, the remainder of the frame being completely upholstered. In such furniture the art of the upholsterer reached its height through the use of elaborate tufting, tassels, and braids.

The influence of William Morris

The English poet and artist William Morris has been called the father of the modern movement. Critical of the shoddiness of the machine-produced goods of his own day, he turned for inspiration to the handcraftsmanship of the Middle Ages and, basing his own work on their designs and methods, attempted to revive a respect for fine craftsmanship and to stir the aesthetic sense of his contemporaries (Figure 42). His influence, though important, might have been greater if, instead of turning away from the machine, he had applied his high ideals to discovering a way in which machines might be used to the best advantage. Morris' followers in the field of cabinetmaking included such designer-craftsmen as Ernest Gimson and the Barnsley family who, working with a few assistants, produced small quantities of high-quality handmade furniture, the craftsmanship of which has never been rivalled. The example of Morris and his followers was so widely copied on the Continent that many people believe modern furniture design originated exclusively there.

During the third quarter of the century, there was a movement in England toward greater simplicity and aesthetic beauty in furniture. The straight and simple lines of Japanese design served as a source of inspiration. The result was the aesthetic, or artistic, style; its chief exponents, producing both designs and furniture, were Edward Godwin and Christopher Dresser.

Art Nouveau style

Henry van de Velde, a Belgian architect and designer, followed in the footsteps of William Morris and was the conscious propagandist of the Art Nouveau style, which flourished from about 1893 to 1910. Characterized by moving, sinuous curves, the style found its inspiration in organic and natural forms and in the Japanese prints that were so popular in Europe during the third quarter of the 19th century. Van de Velde's furniture was often designed *en suite* so that it would give an effect of totality to a room. The interiors of a house in Brussels, created by another Belgian architect, Victor Horta, well illustrate the sinuous curves and natural forms employed by the Art Nouveau designers. The movement was also adopted in France where Hector Guimard was one of its chief exponents. A variant of the style is seen in furniture produced by the Scottish architect Charles Rennie Mackintosh (Figure 73). The Art Nouveau style in furniture design was not as popular in England or in the United States as it was on the Continent. (J.T.B.)

Modern. After the late 19th century, furniture design in the West was divided into two main categories: revivals of past styles—only occasionally precise reproductions, more often free adaptations; and various expressions of changing modern life. The latter category absorbed the best as well as the most progressive talents of the era.

Modern furniture design after World War I was of three kinds: functionalist modern—progressive, adhering to an aesthetic of the machine and often designed by leading architects; transitional modern, which came to be called contemporary and was infused with elements from the past; and commercial modern, called "Borax" because hawkers of that cleanser used to offer premiums, and the word became associated with extra values which commercial furniture often offered by the manner in which it was advertised, or in overblown forms and gaudy veneers. All furniture design was influenced by the social and economic trends of the era: formal living declined; mechanization of household labour expanded; living spaces shrank, particularly in height; and home entertainment became important. After World War II, especially, people married at a younger age, total population growth accelerated, and a generally rising standard of living was enjoyed by a vastly enlarged middle-income group. Furniture became smaller, lighter, easier to maintain, and more widely distributed.

Functionalist modern. About 1925, a new rationality began in furniture design, stimulated by the emergence of progressive experiments typified in the works and theories of the Bauhaus, a revolutionary German school of arts and crafts established in 1919 and staffed by leading architects, designers, and painters until Hitler closed it in 1933. Bauhaus instruction used crafts as experimental techniques and trained students to design for mass production. Low price levels, maximum utility, good quality, and simple, clear forms were considered essentials of well-designed consumer goods. The celebration of modern technology in progressive design was the most effective accomplishment of the Bauhaus. Forms, colours, and materials hitherto confined to shops and laboratories were introduced into homes and offices with programmatic earnestness and considerable stylishness. Tubular chrome-plated metal, black Bakelite, and large unframed planes of glass were typical. Much furniture used at midcentury in reception rooms, terraces, kitchens, or dining alcoves derived from Bauhaus originals. The availability of wood in Scandinavia led, in the 1930s, to similar rational, modern furniture, using a variety of laminating techniques. Related, more ambitious experiments in three-dimensional molding of wood laminates were undertaken in the United States around 1940. Then wartime austerity enforced a salutary simplicity.

The Bauhaus designs

After World War II, earlier design activity resumed. Scandinavian designers abandoned advanced technology for a time and launched a victorious campaign for sculptured, solid-wood furniture in matte finishes that notably enlarged the vocabulary of progressive design. Italian furniture was similar in trend, more open to structural and technological experiments but more accented and less acceptable generally. American modern furniture achieved its first international influence in molded plywood and plastic chairs and in semiarchitectural storage units.

Scandinavian designers

Functionalist modern furniture consciously related itself to progressive architecture, which aided its steady growth in the third, fourth, and fifth decades of the 20th century; at the same time it was also encouraged by friendly periodicals, shops, and museums. Educational and cultural agencies earlier in the century had generally opposed modern design, but gradually there was a change in attitude and by mid-20th century, it was accepted.

Transitional modern. Conservative in style (but not imitative), well-constructed, and carefully finished, the best modern furniture earned its reputation of being in good, correct taste. Often relying on handcraft details and on wood, most factories used speeded-up variations of earlier cabinetmaking operations. This, along with the United States' emphasis on artificially stimulated obsolescence, affected all modern design between World Wars I and II. As in the case of stylistic revivals, favourite sources of inspiration for transitional modern were late 18th- and early 19th-century court and country house furniture, with variations in Chinese and Rococo. This furniture served a wide public that found the avant-garde forms and materials too cold and "clinical."

Commercial modern. Most modern furniture designed between 1930 and 1940 was bulky, bulbous, glowingly coloured, glossily finished, and rich with hardware or shiny fabric. It pleased the public but not critics and connoisseurs. Gradually, and more noticeably after 1945, stylistic details filtered down from more progressive design levels to appear as commercial fads, such as sectional seating and storage units, spidery metal frames, and plastic-shell seats; the Victorian whatnot (set of open shelves for the display of bric-a-brac) was revived, freestanding and rectilinear, as the room divider. Convertible sofa beds and radio and television cabinets were almost all designed in the commercial manner. The innovation of foam upholstery was bitterly fought by union workmen around 1940, but in 15 years had become commonplace in sleeping and seating furniture.

In time a continual flow of new production methods effected basic changes. Lighter masses, thinner silhouettes, and new forms made possible by new materials as well as new technologies seemed to put modern furniture design

on the threshold of a new era. By 1970, however, faddism and commercial versions of bizarre and bloated shapes in seating furniture again ushered in a new brand of "Borax." (E.J.Wo.)

EASTERN

China. Remarkably little systematic study has been made of Chinese furniture. Its origins remain comparatively obscure, its workshops mostly unrecorded, its designers unknown; consequently, its dating is extremely difficult. Most of the forms of Chinese furniture, such as the low table and the covered bed, are found in the oldest Chinese paintings in existence; the designs have been remarkably conservative throughout the ages.

Two types of Chinese furniture

Chinese furniture can be divided into two main types: lacquered wood pieces either inlaid with mother-of-pearl or elaborately carved, and plain hardwood pieces.

Of the first, almost nothing is known, and dating of pieces is possible only from the designs of decorative motifs, such as dragons and peonies, and from their background motifs. The most important historically in this class are black lacquer pieces inlaid with mother-of-pearl that have been preserved in the Imperial repository (Shōsō-in) in Japan from the 8th century. Of the red lacquers, such as seats and tables, the earliest pieces date from the Ming dynasty (1368–1644); their workmanship is characterized by softer contours and freer, more spirited designs than the later pieces of the Ch'ing dynasty (1644–1911/12) (Figure 74). These lacquered objects influenced European cabinetmakers.

Plain hardwood furniture is frequently encountered. Its deserved popularity both in China and the West has been won by its classical simplicity, reserved ornament, and lack of pretense. In these products of the finest workmanship, purity of line, plastic strength, and a flawless polish produce a harmonious, solid effect (Figure 48).

A Chinese house requires less furniture than a Western house. Correspondingly, the types of furniture are fewer, being limited mainly to wardrobes, chests, tables both high and low of all types and shapes (altar and couch tables, for example), stools, beds (sometimes testered with curtains), screens and stools for use by the bed, and chairs.

Although the fundamentals of Chinese joinery must have been formed a millennium before the modern era, the great development in Chinese furniture took place with the introduction of Buddhism from India during the first centuries AD. Before that time the Chinese had sat cross-legged, or knelt on the floor or on stools. Buddhism introduced a more formal kind of sitting on stiff, higher chairs with back rests and with or without side arms. The chests and armoires are superb examples of careful joinery and often have finely worked metal mounts that greatly enhance the beauty of their solid design.

A number of hardwoods were used for the plain furniture: purple sandalwood (the most distinguished); rosewood of many varieties, mostly imported from Indochina and called "old," "new," and "yellow"; redwood; burl (especially for inlay); and so-called chicken-wing wood. Rosewood in its many varieties is perhaps the most frequently encountered and the most popular for its seeming translucence and satin, soft finish. It is above all the faultless workmanship, so typically Chinese, and the fine polish of Chinese furniture that attracts the Westerner. It was the Chinese respect for the spirit of wood and their command of line, curve, and cubic proportions that became the ideal of the 18th-century Western cabinetmaker.

Japan. Japan was one of the few civilizations that did not develop many specialized furniture forms. Instead, the interior architecture of the house, with the garden as its focal point, served the aesthetic and social requirements that furniture has served in many societies. The chief requirement for the few forms that were developed was that they be easily movable.

Japanese furniture forms

Thin mats made of rice straw called tatami covered the floors and were used for sitting. The tatami utilized only natural patterns for decoration, although they often were bound in cloth. Cloth cushions were also used, as were small tables of wood or lacquer, either folding or rigid. Dressing tables and writing tables were specialized forms that evolved from the simple table (Figure 49). The folding screen was an indispensable adjunct to the other furnishings as it could be moved to change the entire aspect of the room. The one stationary piece was the *shoin*, a type of bay window from which extended a fixed desk used for reading.

Japanese furniture forms have changed little for centuries. Because there are few extant pieces from the early periods, information about early furniture is gleaned from literary descriptions, engravings on mirrors, clay images, and graphic representations.

India. India's place in the history of furniture is that of an adapter or transformer of imported Western styles

Photograph, American Heritage Publishing Co., Inc

Figure 74: The Ch'ien-lung emperor, art collector and skilled painter, with tables, screen, and daybed from his furniture collection, China, 18th century.

rather than a creator of independent styles of its own. Domestic furniture in the sense in which it is known in Europe was not traditional in India before the 16th century, and even such familiar objects as tables and chairs were rarely used until the spread of Portuguese, Dutch, and English furniture.

It was precisely the difficulty of obtaining suitable furniture locally for their settlements that encouraged the European traders to export Western prototypes for copying. It was soon found, however, that the Indian craftsman, although an inaccurate copyist, was a skilled and imaginative adapter of foreign decorative detail. This led to the emergence of an independent Indo-European style of furniture that was much admired for its own sake and subsequently exerted fresh influences in the West. Early Indo-European furniture can be divided into two distinct groups, according to whether the influence was primarily Portuguese or Dutch. (The English did not exert a national influence on styles until the late 18th century.)

Two groups of Indo-European furniture

The Indo-Portuguese group includes a northern Indian, or provincial Mughal, style and a southern, or so-called Goanese, style. The former is artistically the more interesting and includes a variety of furniture decorated with inlaid bone or ivory on ebony and other dark woods. Tables and writing cabinets in the Italian Renaissance form are found in this category because this was the dominant style in Portugal.

The second Indo-Portuguese style, sometimes called Goanese (though in fact more probably made on the Malabar coast, south of Goa), is more stereotyped in form and in decoration. It is distinguished by large and rather cumbersome cabinets of a type known in Portugal as *contador*, the inlay ornament being either geometrical or semiabstract. The Indian contribution to this style is more inhibited and lacks altogether the charm and fancifulness of northern Indo-Portuguese furniture.

Indo-Dutch furniture is easily distinguishable from Indo-Portuguese, since it reflects contemporary Dutch taste as clearly as the latter reflects Portuguese. There are two types of Indo-Dutch furniture. The first, which was made on the Coromandel coast, was mainly in light-coloured woods, the decoration being inlaid bone, incised and lacquered. The second is a style of carved ebony furniture which, although commonly found in India and often thought to be Indian in origin, was in fact made at Batavia (modern Djakarta) in Java, the Dutch administrative headquarters in the East. The carved relief decoration of the ebony furniture is floral in character and closely related to the flowering-tree style of contemporary Indo-Dutch embroidered bedspreads and hangings in which the tulip is prominent.

Indo-Dutch furniture

With the growth of British power in India in the 18th century, all Indo-European furniture styles came increasingly under English influence. Whole suites were made in ivory in the manner of Chippendale and Sheraton, not only for European buyers but also for Indian rulers who increasingly favoured European styles of furniture.

In the 19th century, Indian artistic standards degenerated, as is clearly reflected in the furniture of the period. The emphasis was on decorative elaboration for its own sake and, although much 19th-century Indian wood carving shows great technical skill, this rarely compensates for formlessness and stereotyped ornament.

(J.T.B.)

RUGS AND CARPETS

The word carpet was used until the 19th century for any cover made of a thick material, such as a table cover or wall hanging; since the introduction of machine-made products, it has been used almost exclusively for a floor covering. Both in Great Britain and in the United States the word rug is often used for a partial floor covering as distinguished from carpet, which frequently is tacked down to the floor and usually covers it wall-to-wall. In reference to handmade carpets, however, the names rug and carpet are used interchangeably and are so used in this section, which deals almost exclusively with handmade products. Since such carpets are not always intended for use on the floor, the section extends the term rugs and carpets to cover products intended for other uses as well.

Handmade carpets are works of art as well as functional objects. Indeed, many Oriental carpets have reached such supreme heights of artistic expression that they have always been regarded in the East as objects of exceptional beauty and luxury in the same way as masterpieces of painting have been in the West. Handmade carpets are discussed in this section in terms of their elements of design, material, technique, ornament and imagery, use, and stylistic characteristics in different periods and cultures.

Elements of design

FIELD AND BORDER DESIGNS

Designs usually consist of an inner field—the pattern in the centre of the carpet—and a border. The latter serves, like the cornice on a building or the frame on a picture, to emphasize the limits, isolate the field, and sometimes control the implied movements of the interior pattern. The design of inner field and border must harmonize pleasingly, yet remain distinct.

The border consists of a minimum of three elements: a main band, which varies greatly in width according to the size of the rug and the elaborateness of the field design, and inner and outer guard stripes, decidedly subordinate bands on either side of the main band. The guard stripes may be the same on both sides of the main band or be different. The most common decoration for the field is an allover pattern, a panel composition, or a medallion system. The allover pattern may be of identical repeats (Figure 75), either juxtaposed or evenly spaced, though the latter, while common on textiles, is rare on carpets; or it may be of varied motifs in a unified system (*e.g.*, different plant forms of about the same size), but even this freest type of design almost invariably includes bilaterally balanced repetitions. The varied motif type of design is found most typically in formalized representations of the parks or woods that were a feature of Persian palace grounds.

Types of field decoration

Another type of allover design appears to be entirely free but is actually organized on systems of scrolling stems, notably on the east Persian carpets of the 16th and 17th centuries.

The value of panel subdivisions for controlling patterns had been discovered in a simple rectangular version by the Upper Paleolithic period (*c.* 25,000 BC), and panel systems have been a basic form of design since 4000 BC, when pottery painters were already devising varied systems. On carpets, the lattice provides the simplest division of the field, often a diagonal lattice as on an embroidered

Figure 75: Detail of a Persian *kilim* from Sehna (Sanandaj), Iran, 19th century. A tapestry-woven wool rug with an allover identical repeat pattern of *bōteh* (leaf with curling tip) in rows. In the Victoria and Albert Museum, London. Full size 1.65 × 1.19 m.

carpet found in an excavated tomb (1st century BC to 1st century AD) at Noin Ula in northern Mongolia; the diagonal scheme also appears on Sāsānian capitals and in Coptic tapestries. But a characteristic field design of the Persian court carpets of the Shāh ʿAbbās period, the so-called Vase pattern, is constructed from the ogee, a motif that became prominent in Middle Eastern textile design in the 14th century. Simple rectangular panelling—really a large-scale check—is typical of one style of Spanish rugs of the 15th and 16th centuries.

Medallion carpets

The most frequent medallion composition consists of a more or less elaborate medallion superimposed on the centre of a patterned field and often complemented with cornerpieces, which are typical quadrants of the central medallion (Figure 76). But multiple-medallion systems also are developed: either a succession or a chain of medallions on the vertical axis; two or more forms of medallions alternating in bands, a scheme typical of the Turkish (Ushak) carpets of the 16th and 17th centuries; or systematically spotted medallions that may or may not be interconnected or that may interlock so that the scheme logically becomes an elaborate lattice.

Persian carpets of the 15th–17th century commonly have multiple-design schemes; that is, composition systems on two or more "levels." The simplest is the medallion superimposed on an allover design, but more typical are subtler inventions such as two- or three-spiral stem systems, sometimes overlarded with large-scale cloud bands, all intertwining but each carried independently to completion. The finer Vase carpets have double or triple ogival lattices set at different intervals (staggered), each with its own centre, and tangent motifs that also serve other functions in the other systems. What at first sight appears to be a great multiplicity of independent motifs thus proves on careful examination to be ingeniously contrived and firmly controlled.

Occasionally, stripe systems are used, either vertical or diagonal; but this conception is more natural to shuttle-woven fabrics, and, when employed in the freer techniques of rug weaving, it is probably an imitation of textiles.

Figure 76: Persian silk carpet from Kashan, Iran, late 16th century. The field is decorated with a central medallion, surrounded by a wreath of small cartouches and framed by corresponding cornerpieces. In the National Gallery of Art, Washington, D.C. 2.41 × 1.65 m.

DESIGN EXECUTION

Transferring the design is done in various ways. It can be transferred to the carpet directly from the mind and hand of the craftsman or indirectly from a pattern drawn on paper. Using the latter technique, a rug can be executed directly from the pattern, or the design can be transferred first to a cartoon. The cartoon, or *talim*, is a full-size paper drawing that is squared, each square representing one knot of a particular colour. The weaver places the *talim* behind his loom and translates the design directly onto the carpet. The cartoon is used for reproduction of very intricate designs and as a master pattern for the production of more than one carpet. Many of the finest Oriental rugs, which achieve a magnificent effect through wealth of detail, are thought to have been woven from cartoons drawn by manuscript illuminators. Such methods of transfer result in unavoidable irregularities of pattern that, because they are signs of the artistic individuality of the craftsman, lend a particular charm to the handwoven carpet. The major difference between handmade and machine-made carpets is that the mechanical transfer of design in the latter creates a uniformity of pattern, obliterating signs of individual workmanship.

COLOUR

From earliest times until the late 19th century, only natural dyes were used. Some have come from vegetables such as madder, indigo, sumac, genista, and woad; some from minerals such as ochre; and some from animals, mollusks, and insects. Most have been improved by the addition of various chemicals, such as alum, which fix colours in the fibre. Except for dark brown to black dyes, which have high iron-oxide content that often decomposes fibres, natural dyes have proved to be excellent; they have remarkable beauty and subtlety of colour, and they are durable. Much of the charm of antique carpets lies in the slightly varying hues and shades obtained with these natural dyes. In the 19th century, synthetic, aniline dyes were developed, becoming popular first in Europe and, after 1860, in the East; but their garish colours and poor durability were later thought to outweigh the advantages of brilliance and quick application, and natural dyes regained favour with many craftsmen. More recently, synthetic dyes have been improved.

Natural dyes

Materials and technique

Most carpets are made of sheep's wool, which is durable, dyes readily, and handles easily. Camel or goat wool is rarely used. Too dull to make an attractive pile, cotton's strength and smooth yarn make it an ideal warp (see below); it is used in the East for the entire foundation or for the warp only.

Silk is so expensive that its use is restricted; but no other material produces such luxurious, delicate rugs, displaying subtle colour nuances of particular charm in different lights. Some of the finest 16th- and 17th-century Persian carpets are entirely of silk. It has never been used for knotting in Europe; but often since the 15th century it has augmented wool in the weft of European tapestries.

Linen was used in Egyptian carpets, hemp for the foundations of Indian carpets; and both materials are used in European carpets. Since around 1820, jute has been used in the foundation of machine-made carpets.

Knotted pile carpets, combining beauty, durability, and possibilities for infinite variety, have found greatest favour as floor coverings. Long ago, weavers first began to produce pile fabrics or fabrics with a surface made up of loops of yarn, attempting to combine the advantages of a woven textile with those of animal fleece. Knotted pile is constructed on the loom on a foundation of woven yarns,

of which the horizontal yarns are called weft yarns and the vertical are called warp yarns. Coloured pile yarns, from which the pattern is obtained, are firmly knotted around two warp yarns in such a way that their free ends rise above the woven foundation to form a tufted pile or thick cushion of yarn ends covering one side of the foundation weave. The knots are worked in rows between several interlocking, tautly drawn weft yarns that keep every row of knotted tufts securely in place in the foundation. When a row of knots is tied, it is beaten down against the preceding rows with a heavy mallet-like comb so that on the front the pile completely conceals both warp and weft. When a certain area has been woven, the pile ends are sheared to an even height: short on the more aristocratic type and as much as an inch (2½ centimetres) on some shaggy nomadic rugs.

Types of knots

There are various ways of knotting the pile yarn around the warp yarn. The Turkish, or Ghiordes, knot is thought to be the oldest. It is used mainly in Asia Minor, the Caucasus, Iran (formerly Persia), and Europe. The Persian, or Sehna, knot is used principally in Iran, India, China, and Egypt. The Spanish knot, used mainly in Spain, differs from the other two types in looping around only one warp yarn. After the 18th century it became extremely rare. The kind of knot used affects the delicacy and tightness of the pile. Knotting each pile yarn by hand is comparable to setting small pebbles in a mosaic, and expert execution is vital in achieving a beautiful finished product. Angular-patterned carpets requiring only a coarsely knotted pile are easier to produce than curvilinear and finely patterned ones, which require finer material and a much more densely knotted pile for clear reproduction of their intricate designs. Some Chinese carpets have fewer than 20 knots per square inch (three per square centimetre); certain Indian ones, more than 2,400. The highest density can be achieved with the Persian, or Sehna, knot.

Brocading can be added to the pile, heightening its colourfulness. The gold and silver thread in this procedure lies flat against the woven foundation, giving the appearance of low relief (Figure 77, left). Metal threads, however, quick-wearing and with diminishing lustre, are less suitable as floor coverings than as hangings.

Many carpets do not have knotted pile. Called *kilims*, they are woven similarly to tapestries. The weft yarns of a given colour area never cross into another area, and if the weft yarns of different colour areas are hooked around adjacent warps rather than around one another or around warp yarn, small slits are created where different colours meet (Figure 77, centre). In fully brocaded Soumak carpets, one or two rows of coloured pattern weft alternate with an invisible functional weft. Brocading with passes of alternate rows given a differing direction, or slant, produces a herringbone effect (Figure 77, right).

Embroidery has rarely been used on floor coverings. Embroidered rugs are almost exclusively European and American, except for certain Turkmen *kilims* and Turkish *cicims* (ruglike spreads or hangings). Only relatively strong backings can be used, such as in appliqué work or embroideries done in designs of counted stitching (the cross-stitch, and the gros point and petit point of needlework) that cover the entire surface.

Ornament and imagery

INDIVIDUAL MOTIFS

Three main classes of motifs are used: geometrical; conventional, or stylized; and illustrative, or naturalistic. The geometrical repertoire is built up from variations and combinations of meanders, polygons, crosses, and stars. Meanders, chiefly for borders, range from the simple serration employed from earliest times to fairly complex hooked forms, characteristically the angular "running wave," or

"Greek key," which is also very ancient. Little trefoil (trilobed) motifs are used for guard stripes in the Caucasus, central Iran, and India. Chief among the polygons employed are the lozenge and the octagon. The Maltese cross is frequently used, as is the gamma cross, or swastika. Purely geometrical stars are usually based on the cross or the octagon. Many of these motifs, which are rudimentary and very ancient, may have originated in basket weaving and the related reed-mat plaiting, for they are natural to both techniques; but in rug weaving they have survived chiefly in the work of Central Asia, Asia Minor, and the Caucasus, in both pile-knotted and flat-woven fabrics.

Arabesque carpets

One of the principal stylized motifs in 16th- and 17th-century Persian carpets is the so-called arabesque, an ambiguous term that generally implies an intricate scrolling-vine system. In a common Persian ornamental scheme, two asymmetrical members cross at an acute angle, forming a lilylike blossom, and then describe curves in opposite directions, readily continuing into further scroll systems (Figure 78). This highly individual form was begun in China in the late Chou period (*c.* 600 BC), notably on a few bronze mirrors, and was beautifully developed during the Han dynasty (206 BC–AD 220). It appeared in Persia in the 12th century (on pottery and architectural stucco ornament), possibly influenced by the Chinese form.

Directly traceable to China are the cloud knot and cloud band, or ribbon—both in use by the Han period at least and with a continuous history thereafter. The cloud knot, a feature of the Persian court carpets of the time of Shāh ʿAbbās, was continued to the end of the 18th century. The cloud band became important on 16th-century carpets; it was employed with especial elegance and skill by Persian designers and perhaps most beautifully in Turkish court carpets, which owed much to Persian inspiration. The cloud band and knot motifs moved from Syrian textile design into Asia Minor with the Ottoman Turkish conquest in the 15th century and became typical of one group of 16th–17th century Turkish carpets.

Palmettes, a second major class of stylized motifs dominant in a considerable range of carpet designs from Asia Minor to India, originated in Assyrian design as stylizations of the palm, a symbol of vitalistic power that was often, if not always, associated with the Moon (Figure 79). Many of the almost uncountable variations that developed through the centuries continued to refer directly to the palm. As early as the 1st millennium BC, however, others

Figure 78: Detail of a wool Persian arabesque carpet from Kerman, Iran, late 16th century. A system of double intersecting arabesque bands covers the field. In the Metropolitan Museum of Art, New York. Full size 6.05 × 2.49 m.

Figure 79: Detail of a wool Persian carpet from Kurdistan, Iran, late 18th century. Stylized palmettes dominate the field, which also includes motifs derived from the Chinese lotus blossom. In the Metropolitan Museum of Art, New York. Full size 6.96 × 2.69 m.

derived from the lotus blossom, a complementary motif connected primarily with the fertility symbolism of the Sun. Still others involved the pomegranate, another fertility symbol, while yet another group presented the vitalistic emblem of the vine, this last design being built on the single leaf. The forms of these four main types of palmettes found in Oriental rug designs are directly descended from styles current in textile designs from the 4th century onward and are often modified by Chinese influences. The patterns in the 16th and early 17th centuries were beautifully and realistically elaborated, and blossoms such as the Chinese peony sometimes compete with the more stylized lotus. The lanceolate leaf, often associated with palmettes (especially in east Persian designs), is generally stylized. The chalice, fan, and half-palmette, all evolved from the palmette and used in Oriental rugs, were also used in 17th- and 18th-century European designs.

Naturalistic motifs

Outstanding among the more naturalistic plants are cypresses and blossoming fruit trees, symbolizing life eternal and resurrection, respectively. Willows and jasmine flowers are prominent in the Shāh ʿAbbās Vase carpet and tulips in Turkish court carpets. Many minor foliate and floral forms had no specific botanical identification, though they give a realistic effect (Figure 80). Naturalistic red or pink roses were widespread in European designs by the mid-16th century. Under European influence, they appeared in Oriental designs, particularly Persian, in the later 19th century.

The most important illustrative motifs, other than naturalistic plants, are those connected with the garden and the hunt: many small songbirds (in Persia, especially the nightingale); the pheasant (*feng-huang*), taken over from China and much favoured in the 16th century; occasionally the peacock; lions and a semi-conventional lion mask, sometimes used as the centre of a palmette; tigers; cheetahs; bears; foxes; deer of numerous species; goats, sometimes picturesquely prancing; the wild ass, a fleet prey; ferocious-looking Chinese dragons, and the gentle *ch'i-lin*, a fantastic equine also imported from China. Fish sometimes swim in pools or streams or are conventionally paired to suggest a shield, or escutcheon, in the borders

Figure 80: Indian wool floral carpet, Mughal, 17th century. The field is decorated with an allover pattern of naturalistic flowering plants. In the Metropolitan Museum of Art, New York. 4.27 × 2.01 m.

of the carpet. Huntsmen, usually mounted, are the major human figures, though musicians are also depicted. Angels are occasionally present (see Figure 81).

The underlying theme of both the stylized and naturalistic vocabularies is nearly always fertility or abundance. The great Persian carpet of Ardabīl (1539–40; Victoria and Albert Museum, London), for example, embodies a huge golden stellate medallion, developed from the multiple-pointed rosette that from time immemorial symbolized the Sun. At its centre are four lotus blossoms floating on a little gray-blue pool, which represents the source of rain in the heavens. The medallion thus symbolizes the two basic vitalizing elements—Sun and water. As proof of its magical potency, a complex system of tendrils and blossoms issues from it (see Figure 84).

Oriental versus European design

In Oriental carpet design, a flat surface pattern is always emphasized, even where small details are plentiful. European designs, however, tend more toward the illusionistic effects of painting, often using shading and picture-like compositions and incorporating architectural motifs and even portraiture. This tendency is particularly evident in French carpets of the 17th and 18th centuries.

SYMBOLISM OF OVERALL DESIGN

In addition to the symbolism inherent in individual motifs incorporated into the design of the carpet, the total design—indeed, the carpet itself—can be symbolic, as are some of the earliest Persian designs. The ultimate example is the Spring (or Winter) of Khosrow Carpet made for the audience hall of the Sāsānid palace at Ctesiphon (southeast of Baghdad) in the 6th century. The carpet has not survived, but, according to written records, it represented a formal garden with watercourses, paths, rectangular beds filled with flowers, and blossoming shrubs and fruit trees. Yellow gravel was represented by gold; and the blossoms, fruit, and birds were worked with pearls and different jewels. The outer border, representing a meadow, was solid with emeralds. Made of silk and measuring about 84 feet (25.6 metres) square, the carpet must have been overwhelmingly splendid when the great portal curtains of the hall were drawn back and the sun flooded the interior.

This dazzling carpet symbolized the divine role of the king, who regulated the seasons and guaranteed spring's return, renewing the earth's fertility and assuring prosperity. On another plane, it represented the Garden of Eden, a symbol of eternal paradise (the English word paradise is ultimately derived from the Persian word which means "walled park"). With its flowers, birds, and water, it symbolized deliverance from the harsh desert and the promise of eternal happiness.

This most sumptuous of fabrics made a profound impression on everyone, especially the Persians. For centuries it bewitched Persian imagination, becoming a legend in history, poetry, and art. Vain attempts at emulation were made by Oriental craftsmen for more than a millennium; and though its realistic depiction has disappeared, the

Garden of Eden concept lingers on in Oriental designs. The garlands, vines, flowers, trees, animals, and beasts all strive to create a landscape, picturing hunting scenes or game, lakes with water birds, and often images of supernatural or celestial beings, such as jinn, houris, or a gathering of the blissful righteous at a banquet or dance (Figure 81). Accompanying verses support the image, lyrically extolling the carpet as a garden, for example, or a blooming meadow and comparing its beauty to that of the Garden of Eden.

Uses of rugs and carpets

Carpets originated in Central and Western Asia as coverings for beaten-earth floors. From time immemorial, carpets covered the floors of house and tent as well as mosque and palace. In the homes of wealthy Eastern families, floor coverings serve an aesthetic as well as a practical function. Rugs are often grouped in a traditional arrangement, partly to allow for simultaneous display; and the carpet's size and shape is determined by the intended place within that arrangement. There are usually four carpets. The largest, called *miān farsh,* usually measuring some 18 feet by 8 feet (5.5 by 2.5 metres), is placed in the centre. Flanking the *miān farsh* are two runners, or *kanārehs,* which are mainly used for walking and which measure some 18 feet by 3 feet (5.5 by 1 metre). The principal rug, or *kellegi,* averaging 12 feet by 6 feet (3.7 by 1.8 metres), is placed at one end of the arrangement of three carpets, so that its length stretches almost completely across their collective widths.

The prayer rug

The intended use sometimes determines both design and size, as in the prayer rug, or *namāzlik.* Because a Muslim must carry it everywhere, the prayer rug is relatively small (Figure 82, right). Design, naturally linked to religious imagery, is characterized by the *mihrāb,* or prayer niche (an imitation of the prayer niche in the wall of a mosque), the apex of which could be pointed toward Mecca. But other religious properties also appear, such as hanging lamps, water jugs, or "hand prints" to mark the place of the worshipper on the rug.

Until mid-17th century, Asian carpets imported into Europe were considered too precious to serve as permanent floor coverings. Placed on the floor only on church holidays or in an aristocrat's presence, they were otherwise used on the wall or to cover tables, benches, and chests; and, particularly in Italy, they were hung over balconies as decoration during festivals. Taking this European attitude into account, the Egyptian manufacturers created several unusual shapes and sizes for the European market: square, round, and cruciform carpets, obviously designed for tables rather than floors (Figure 82, left). During the 17th century, covering the entire floor with costly knotted carpets became fashionable. The mid-20th century witnessed a boom in antique-carpet prices that resulted in choicer pieces ending up back on the wall.

Table carpets

Oriental carpets frequently served many uses besides covering floors. They made handsome curtains, served as tribute money, and were frequently gifts of one state to another. They were used as blankets, canopies, coverings for tent openings, and tomb covers. They have also made excellent saddle covers and storage bags for use in tents. Such modest rugs were always close to the life of the people, who lavished care on them and into them wove life-protecting symbols. Other, more bizarre, uses have included assisting in the demise of Baghdad's last caliph—who in 1258 was wrapped in a carpet and beaten to death—and dramatically enhancing Cleopatra's introduction to Julius Caesar, when she stepped out of an unrolled rug. In less well-documented instances, they have assumed magical properties and taken flight.

Periods and centres of activity

Floor coverings of plaited rushes have been used at least since the 4th or 5th millennium BC, and rush weaving

in the Middle East had reached a high standard by medieval times.

ORIENTAL CARPETS

Oriental carpets are those made in Western and Central Asia, North Africa, and the Caucasus region of Europe. Rug design, in Western Asia at least, had gone beyond felt and plaited mats before the 1st millennium BC. A threshold rug represented in a stone carving (now in the Louvre) from the 8th-century-BC Assyrian palace of Khorsabad (in modern Iraq) has an allover field pattern of quatrefoils (four-leafed motifs), framed by a lotus border. Other Assyrian carvings of the period also show patterns that survive in modern designers' repertories.

Excavation of royal graves, dating from the 5th to the 3rd century BC, at Pazyryk, in the Altai Mountains of Southern Siberia, has uncovered the oldest known examples of knotting. The finds include various articles of felt with appliqué patterns and a superb carpet with a woollen pile, knotted with the Ghiordes, or Turkish, knot (Hermitage). The carpet, probably of Persian origin, measures $6 \times 6\frac{1}{2}$ feet (1.8×2.0 metres). The central field has a checkerboard design with a floral star pattern in each square. Of the two wide borders, the inner one shows a frieze of elk, the outer one a frieze of horsemen.

Knotting was not necessarily the only or even the most important method of carpet making. Felt carpets were used for a long time in Central and East Asia, as indicated by magnificent 1st-century-AD specimens from Noin Ula in Northern Mongolia (1st century BC to the 1st century AD; in the Hermitage) or those in the Shōsō-in (Japanese Imperial storehouse) in Nara near Osaka (before the 8th century). The costly rugs with figure motifs and gold mentioned by Greek and Arab writers may have been woven or embroidered and were probably exhibited on the wall as well as on the floor. The large carpet made in the 6th century for the Sāsānid palace in Ctesiphon (see above *Ornament and imagery: Symbolism of overall design*) is the most famous; but other Oriental courts, such as the caliphate at Baghdad (8th–13th century), also used valuable carpets.

Early Anatolian and Caucasian rugs

In the 13th, 14th, and 15th centuries, Asia Minor and the Caucasus produced coarse, vividly coloured rugs with stars, polygons, and often patterns of stylized Kūfic writing. A special group with simple, highly conventionalized animal forms was also woven; the most important of these carpets are represented by seven fragments of strong, repeating, geometric patterns in bold colours—red, yellow, and blue—found in the mosque of 'Alā' ad-Dīn at Konya in Anatolia and now in the Museum of Turkish and Islāmic Art, Istanbul. They probably date from the 13th century. In the Staatliche Museen zu Berlin and in the Nationalmuseum at Stockholm are two primitive rugs, one, a highly conventionalized dragon-and-phoenix combat (Figure 83), the other, stylized birds in a tree. Both of these rugs are probably early 15th-century Anatolian.

Later, many rugs of finer weave, more delicate patterns, and richer colour—mostly geometric and possibly from Seljuq looms in Asia Minor—appeared in Europe. They were depicted by Flemish painters, such as Hans Memling, Jan van Eyck, and Petrus Christus, with such skill that the separate knots are sometimes visible. Many of these designs are repeated in the Bergama district of Asia Minor and the Southern Caucasus today, a complication when dating work.

Persia. Little is known about Persian carpet making before the 15th century, when the art was already approaching a peak. The Mongol invasion of the 13th century had depressed Persia's artistic life, only partly restored by the renaissance under the Mongol Il-Khan dynasty (1256–1353). Although the conquests of Timur Lenk (died 1405) were in most respects disastrous to Persia, he favoured artisans and spared them to work on his great palaces in Turkistan.

Under Timur's successor, Shāh Rokh (died 1447), art flourished, particularly carpets. Their production exclusively by palace workshops and court-subsidized looms gave them unity of style; and a sensitive clientele and lavish royal support guaranteed perfect materials and the highest skill: sheep were especially bred, dye plantations were cultivated like flower gardens, and designers and weavers could win court appointments. These conditions continued under the Ṣafavīds (1501/02–1732).

Figure 83: Wool carpet with octagons containing a stylized dragon-and-phoenix combat motif, attributed to Anatolia, *c.* early 15th century. In the Staatliche Museen zu Berlin. 172 × 90 cm.

In the 15th century the art of the book, which had long been considered the supreme artistic accomplishment and already had behind it centuries of superb achievement, reached a degree of elegance and sophistication unknown either before or since. The bindings, frontispieces, chapter headings, and, in the miniatures themselves, the canopies, panels, brocades, and carpets that furnished the spaces all received the richest and most elegant patterning. These beautiful designs were appropriated in various degrees by the other arts and account in no small measure for the special character of the court carpets of the period, the variety of colour, the ingenuity and imaginative range of pattern schemes, and the superlative draftsmanship that is both lucid and expressive.

Among the products inspired by book illumination were the Medallion carpets of northwest Persia, which consist of a large centre medallion connected with pendants or cartouches on the long axis and with quarter-section designs of the medallion in the corner areas. First used on ornamental pages and bindings of Persian books, on carpets this arrangement provided an effective centre and allowed several layers of designs to overlap because the medallions could cover multiple vine and flower patterns. The depiction of the latter motifs is more relaxed than their medieval rendering, and new motifs (inspired by painting) such as animals, humans, and landscapes began to be worked in.

The world's most famous Persian carpets

A special court atelier, possibly located in Soltānīyeh, translated the most gorgeous illuminations into carpets. Among the 12 or so surviving examples are the world's most famous carpets, each a masterpiece of superb design, majestic size, purity and depth of colour, and perfection of detail. The best known are two carpets from the mosque at Ardabīl in eastern Azerbaijan, Iran, dated 1539–40. The better, skillfully restored, is now in the Victoria and Albert Museum (Figure 84); the other, reduced in size, is

Figure 84: Wool and silk Persian medallion carpet from the mosque of Ardabīl (Iranian Azerbaijan), probably made in a workshop at Tabriz, Iran, dated 1539–40. A gold star medallion is centred on an indigo field of scrolling stems and blossoms. The medallion symbolizes the Sun; at its centre are four lotus blossoms in a pool, symbolizing the source of rain. In the Victoria and Albert Museum, London. 11.51 × 5.33 m.

By courtesy of the Victoria and Albert Museum, London

in the Los Angeles County Museum of Art. An extremely rich, intricate system of stems and blossoms covers a velvety, glowing indigo field, the whole dominated by a complex gold-star medallion. A near rival to the Ardabīl weaving is the Anhalt Carpet (possibly 19th century), named after a previous owner, the Duke of Anhalt, and now in the Metropolitan Museum of Art, New York City. An intricate star medallion dominates a brilliant yellow field covered with scrolling arabesques and fluttering cloud bands, framed by a scarlet border. One of the most beautiful of northwest Persian rugs is the "animal" carpet, half of which is in Kraków Cathedral, Poland, and half in the Musée des Arts Décoratifs. It has the same glowing scarlet and gold as the Anhalt Carpet but with more subtle halftones (buff on yellow, gray on taupe, brown on gray) and represents paradise more pictorially. Historically more important, and in beauty a rival of any, is the great "hunting" carpet in the Museo Poldi Pezzoli in Milan (Figure 85), inscribed: "It is by the efforts of Giyath-ud-Din 'Jami that this renowned carpet was brought to such perfection in the year 1521." A scarlet and gold medallion dominates a deep blue field, covered with an angular network of blossoming stems, across which hunters dash after their prey.

These carpets, in the opinion of many, represent the supreme achievement in the whole field of carpet designing. Nonetheless, other royal workshops were also producing many beautiful rugs. Particularly costly silk carpets with figure motifs (such as the silk hunting carpet in Vienna's Österreichisches Museum für Angewandte Kunst; see Figure 81) were woven in Kashan, Persia's silk centre. Smaller silk medallion carpets were also made there during the later 16th century, their designs mostly variations of the original medallion system. The court manufacture of Kashan also produced silk carpets with a decidedly royal style.

The distinctive rugs called Vase carpets (because of the flower vases in their designs) are generally thought to be Kerman. The pattern usually consists of several lattice systems with profuse blossoms and foliage. Many of these carpets survive as fragments; but only a scant 20 are intact, the finest of which is in the Victoria and Albert Museum. The rugs were apparently not for export but for court and mosque. Woven on a solid double warp, their boardlike stiffness holds them flat to the floor. In Iran they are still called "Shāh 'Abbās" carpets after the monarch of that name. The typically Persian style widely influenced carpets in Kurdistan and the Caucasus and also Indian court carpets, as well as embroideries from Bukhara.

Later in the 17th century, increasing luxury and wealth demanded the production of so many gold- and silver-threaded carpets that soon they were available in bazaars and exported to Europe, where more than 200 have been found. Some were made in Kashan, but many of the finest came from Isfahan. With their high-keyed fresh colours and opulence, they have affinities with European Renaissance and Baroque idioms. The Polish nobility ordered many gold-threaded rugs from Kashan, for Poland and Persia had close relations in the 17th century. Because there had been a rug- and silk-weaving industry using gold thread in 18th-century Poland, these imported Persian rugs, when first exhibited at the Paris exposition in 1878, were considered Polish, especially as nothing quite like them had at the time been found in Persia itself. They were accordingly dubbed "tapis Polonais," or Polish carpets, and the name has stuck. The type degenerated in the later 17th century, materials deteriorating, weaving coarsening, and designs muddling.

Herāt carpets

East Persian Herāt carpets, which were named after their centre of production and were characterized by their combination of a wine-red field and a border of clear emerald green with touches of golden yellow, became known in Europe as the typical Persian carpet. Many of the European artists of the period owned them, and Anthony Van Dyck and "Velvet" Brueghel (Jan the Elder), in particular, rendered them with complete fidelity in datable paintings. Indian princes also were enamoured of them and acquired them by plunder and purchase alike. Their popularity resulted in mass production with all its attendant deleterious effects, and the style finally expired in mediocrity.

Throughout 17th-century Persia, increasing refinement accompanied slackening inspiration. Silk carpets woven to surround the sarcophagus of Shāh 'Abbās II (died 1666) in the shrine at Qom (in Central Iran) were the last really fine achievements in Persian weaving. Even Orientalists have mistaken their finish for velvet; the drawing is beautiful, the colour varied, clear, and harmonious. The set is dated and signed by a master artist, Nī'mat Allāh of Jūsheqān.

At the end of the 17th century, nomads and town dwellers were still making carpets using dyes developed over centuries, each group maintaining an unadulterated tradition. Not made for an impatient Western market, these humbler rugs of the "low school" are frequently beautifully designed and are of good material and tech-

SCALA New York

nique. A great rug industry was developed in western Persia in the Solṭānābād district; and from individual towns come beautifully woven rugs such as Sarūks, with their ancient medallion pattern; Serabands, with their repeating patterns on a ground of silvery rose; and Ferahans, with their so-called Herāti pattern—an allover, rather dense design with a light-green border on a mordant dye that leaves the pattern in relief. The earlier Ferahans (two are known, dated to the end of the 18th century) are on fields of dark lustrous blue with a delicately drawn open pattern. Later, Ferahans degenerated in colour, material, and design. "Low school" rugs maintained their standards down to the later 19th century, when insatiable Western demand ruined their artistry; but in the 20th century fine weaving in Persia has been somewhat revived.

Turkey. After the 16th century, Turkish rugs either followed Persian designs, indeed, were possibly worked by immigrant Persians and Egyptians, or followed native traditions. The former, made on court looms, displayed exquisite cloud bands and feathery, tapering white leaves on grounds of pale rose relieved by blue and emerald green. Turkish patterns embellished stately carpets, designed for mosques or noble residences, with rich, harmonious colours and broad, static patterns. They contrast with the lively, intricate Persian designs, in which primary, secondary, and tertiary patterns often interact with one another in subtle dissonances and resolutions.

Uşak carpets

Turkish styles are best illustrated by the carpets from Uşak in Western Anatolia, in which central star medallions in gold, yellow, and dark blue lie on a field of rich red. So-called Holbein rugs, similar to Caucasian carpets (see below), have polygons on a ground of deep red, dark green, or red and green; they often have green borders and conventionalized interlacing Kūfic script. Such a carpet is depicted in a portrait of Georg Gisze by the 16th-century German painter Hans Holbein the Younger—hence the name. Similarly, a handsome carpet pattern of interlacing yellow arabesques on a ground of deep red appears so often in the paintings of the 16th-century Venetian artist Lorenzo Lotto that they are called Lotto rugs. Carpets with a muted deep-red ground of wonderful intensity, patterned with small medallions, hail, perhaps, from Bergama. In the 17th century they developed into a type known as Transylvanian, so called because so many of them, particularly prayer rugs, were found in Transylvanian churches. They are nonetheless purely Turkish, with rich, quiet colour and sturdy designs. The majority are dominated by a fine red, though a few have faded to the colour of old parchment.

Turkish "bird carpets"

In the 17th century, the "bird carpet," or White Ushak, with conventionalized floral motifs suggesting birds, developed (Figure 86). Surviving examples are serenely beautiful, with fields of soft ivory and various discreet colours.

Eighteenth- and 19th-century "low school" rugs from Asia Minor continued the tradition of blending sober patterns and luxurious colour. Yürük "low school" rugs, made by nomadic Anatolian peoples like the Kurds, have attracted collectors because of their wide range of rich colours and the use of simple patterns, often geometric, that are organized in bold designs, frequently having a diagonal rather than a vertical emphasis. But the chief creations were prayer rugs, more plentiful among the Turks than among the other faithful. Handsome pieces were woven in Anatolia at Melas, Konya, Lâdik, and Kirşehir, Lâdik's being the most brilliant, both in colour and pattern. The most famous Anatolian prayer rugs came from Ghiordes and Kula, mostly in the 18th and 19th centuries; and in the United States they became the first passion of the collector. Regions such as Smyrna (İzmir) produced a great number of utility carpets for the West.

The Caucasus. Fine rugs were woven in the Caucasus

Figure 86: Wool "bird carpet," possibly from Uṣak, Turkey, 17th century. The ivory white ground is patterned with an allover, stylized floral motif reminiscent of a bird. In the Metropolitan Museum of Art, New York. 4.44 × 2.31 m.

from the earliest times. During Persia's long political and cultural dominance, the magnificent carpets produced at the Persian court furnished models for the more ambitious Caucasian rugs, such as those woven for the local nobles, or khans. But the Caucasus has its own individual character; while it borrowed motifs from other areas, it completely transformed them by a furious vigour of design unequalled in the textile world. For example, although the Dragon carpets of Kuba continue medieval Persian motifs, the beasts, recognizable in the earliest Caucasian examples, are later stylized and enclosed in repeated rhomboid designs (Figure 87). This stylization process resulted perhaps from the combination of a taste for abstract design and the poverty of the region. The dense knotting required for curvilinear, natural designs is possible only with fine material, which the Caucasians could not afford. Their rugs, therefore, were of coarse weave, the Dragon carpets often having fewer than 80 knots per square inch (12 per square centimetre).

Caucasian "low-school" rugs

The "low-school" rugs are among the most individual and satisfactory. Their patterns are practically all geometric, densely juxtaposed, generally without organic connection or implied movement; but they are clear, ingenious, and entirely suitable for floor decoration. More recent examples seem a little dry in colour; but rugs woven by the Kazakhs, Sarūqs, and other nomads, are sometimes of flaming brilliance; and the older rugs from Dagestan, Kuba (both west of the Caspian Sea), and Shirvan (on the borders of Iraq and Iran) are done in beautifully clear, discreet, and well-balanced tones.

Shirvan *kilims*, or tapestry rugs, with their broad horizontal stripes, have bold motifs assembled in harmonious colours.

Another type of flat-stitch carpet, brocaded with a mass of loose threads at the back, comes from the Shemakha region (in Azerbaijan). It has mistakenly been called cashmere because of its superficial resemblance to cashmere shawls. The design usually embodies large, beautifully articulated mosaic-tile patterns in rich and sober colours.

Turkistan. The carpets of western Turkistan (wrongly called Bokhara carpets) are made by nomadic Turkmen tribes. Few extant examples are more than 100 years old, though similar rugs have almost certainly been made for centuries. Many older pieces are not intended as floor coverings. Some, called *jovāls*, are bags (about 5 by 3 feet; 1.5 by 1 metre) for storage in tents. Some are saddlebags consisting of two squares of about 2 feet (0.6 metre), joined together. There are also long tent bands (called *kibitkas*) about 1 foot (0.3 metre) wide and perhaps 60 yards (55 metres) long, used for decorating large tents, and rugs used as hangings for tent doorways. Small, squarish rugs and larger ones of about 10 by 7 feet (3 by 2 metres) seem later and were made perhaps mainly for sale. Turkmen carpets have woollen warp, weft, and pile, two lines of weft, and either Sehna or Ghiordes knots. Except for the Baluchi, Turkmen rugs are characterized by a dark-red colouring and geometric designs. After the predominant red, the chief colours are blue, white, and a natural black wool toning pleasantly to brown. The characteristic design is the octagon, or elephant's foot, arranged in rows and columns, often with diamond-shaped figures in between. Door hangings have cross-shaped panelling, smaller pieces a rectangular diaper (allover pattern). Woven end webs and tassels are used freely as embellishments. Carpets made by Turkmen tribes are the Tekke, Yomut, Afghan, Sarūk, Ersar, Beshir, and Baluchi.

Characteristics of Turkmen rugs

Chinese Turkistan. The oldest surviving Chinese Turkistan rugs date perhaps from the 17th century. Most have a silk pile and some metal and gilded thread, with floral, Persian-influenced patterns showing distinct Chinese treatment. Later carpets are loosely woven with the Sehna knot and have a wool or, more rarely, silk pile and a cotton warp. Eighteenth-century examples have rich, dark

Figure 87: Detail of a wool Kuba Dragon carpet, probably from Karabagh or Shirvan in southern Caucasia, 17th century. The dragon, enclosed in an ogee lattice intersected by palmettes and blossoms, is derived from Chinese motifs through medieval Persian models. In the Textile Museum, Washington, D.C. Full size 5.34 × 2.39 m.

Figure 88: Chinese Turkistan three-medallion wool carpet from Khotan (Hot'ien), Sinkiang Uigur Autonomous Region, China, 19th century. The top and centre medallions contain a pomegranate branch and vase motif. The corner filling is a Turkish form of the Chinese cloud scroll. The guard stripe has a stylized Chinese wave pattern, the centre band of the main border a swastika meander. In the collection of Vojtech Blau, New York. 3.71 × 1.83 m.

In possession of Vojtech Blau, New York City photograph Otto E. Nelson—EB Inc

colouring, which became brighter in the 19th century and, at last, excessively crude. There are two main types of design. The Medallion carpet usually has three squarish medallions placed down the centre and, almost invariably, one border with a conventional Chinese pattern of foam-crested waves (Figure 88). This design is generally called Samarkand in the trade, though the rugs themselves come from Kashgar, Khotan, Yarkand (modern Su-fu, Hot'ien, So-ch'e in China's Sinkiang region). The Five-blossom carpet has a floral diaper with groups of five blossoms. The colouring is often red and orange with a little clear blue.

Egypt. Egyptian carpets used to be called Damascus carpets but are now termed Mamlūk, after the Muslim dynasty (1250–1517) that subsidized their manufacture, or Cairene rugs after Cairo, the city in which they were made.

Knotting was thought to have reached Egypt from Asia Minor, but early Cairene carpets differ from Anatolian ones: they are knotted with the Persian knot, and their colours are red, yellow green, and light blue, applied evenly in inner field and border. Moreover, Egyptian designs concentrate on the centre, subordinating surrounding motifs. Border designs match rectangular with square panels. Although filled with plants, the carpet designs seem geometric (Figure 89). The heyday of these rugs occurred during later Mamlūk rule, when there was extensive export.

India. Carpets are less important in India than elsewhere in Asia because the climate makes knotted floor coverings unsuitable. As an art, carpet weaving was brought from Persia by the 16th- and 17th-century Mughal emperors, who subsidized the manufacture of beautiful rugs with an almost silken sheen. Although Indian artistry was influenced by Southern and Eastern Persian carpets, it maintained a native taste for pictorial representation (Figure 90).

Mughal carpets

The carpets made for the courts of the grand Mughals were of extravagant and luxurious beauty. Expense was ignored, and a series of carpets was made with 600 to 1,200 knots per square inch (95 to 190 per square centimetre). Special carpets were of even finer weave, 2,100 knots per square inch (325 per square centimetre; Metropolitan Museum of Art). For the palace of Shāh Jahān (died 1666) a set of rugs was made from the most precious wool, imported from Kashmir and remote Himalayan valleys. But because the sources of the art were in imitation, not in the life roots of the people, these wonderful fabrics never reached the artistic height that characterized many periods of Persian weaving. Once established, the rug industry continued, becoming a jail industry, particularly in the Punjab. Designs degenerated, and good wool was difficult to obtain. Later Indian carpets are thus mostly inferior to Persian work.

China. The rugs of China are recognizable by their characteristic Chinese ornament. Of coarse texture, they are Sehna-knotted on a cotton warp. The pile is thick, smooth-surfaced, and "sculptured" so as to form a furrow at the pattern's contours. Yellow predominates, sometimes intentionally, sometimes as the result of the fading of red and orange. Blue and white are commonly used; but true red, brown, and green are rarely seen.

Some carpets have repeating plant scrolls; others scattered flowers and various Chinese symbols. Frets, or key designs, often decorate the border.

Chinese Pillar carpets

Peculiar to China are Pillar carpets, designed so that when wrapped around a pillar the edges will fit together to form a continuous pattern, usually a coiling dragon (Figure 91). Small mats and seat covers are also common. Chinese rugs are virtually impossible to date, since they vary little with time. Many large carpets have been made for export in the 20th century.

WESTERN CARPETS

Spain. Spain's close ties with Islām after the 8th century made it quick to accept and produce knotted carpets. Early examples of the unusual Spanish knot suggest manufacture as early as the 12th century, but not until the 15th century do enough examples remain to allow grouping of work. Many designs imitate Anatolian forms; others, with coats of arms or Christian emblems, indicate purely European origin. During the 16th century, Renaissance influence was prevalent. The manufacturing centres were Cuenca, Alcaraz, and possibly Almería. The knotted carpet lost ground during the 18th century; and native work, known as Alpujarra (after the district), is embroidered or done in uncut weft-loop technique.

France. In France, too, the stimulus for the production of knotted carpets came from the East; but the designs of the rugs were inspired by contemporary French decoration rather than Oriental carpet design. Jean Fortier and Pierre Dupont won fame knotting pieces in the Hospice de la Savonnerie at Chaillot, which was converted from a soap factory to a carpet factory in the early 17th century. "Savonnerie" became a mark of distinction in French carpets, reaching a zenith during the later 17th century with Louis XIV's immense order for Versailles. Combined since 1826 with the Gobelins factory, the firm still operates. Thick and strong, these carpets consist of a woollen pile on a mostly linen warp. During the 18th century and afterward, many tapestry-woven carpets were made at Aubusson as well as at other tapestry factories. Even though their production has not been confined to that city, they are known as Aubusson carpets.

Savonnerie and Aubusson carpets

The European concept of carpet design, as distinguished from the Oriental concept, is most explicit in the Savonnerie carpets, in which three-dimensional compositions complement architecture, and even portraits are reproduced (Figure 92). The style of such carpets is best seen in sketches of rug design made by Charles Le Brun for Louis XIV (mostly in the Mobilier National in Paris).

United Kingdom and Ireland. The growth of a native craft in the United Kingdom soon followed on the introduction of carpets from Turkey, though 16th- and 17th-century intact specimens number only about a dozen. They are characterized by a hemp warp and weft, medium-fine woollen pile, and the Ghiordes knot. The background usually is green, and there are so many shades of the other colours that the entire number of tints is greater than in Oriental carpets. The designs can be divided into two groups. In the first are typically English patterns resembling contemporary embroidery, often with heraldic devices and dates. The oldest specimen, dated 1570, belongs to the Earl of Verulam. In the second group are many pieces of carpet knotting—called at the time "Turkey work"—imitating Oriental designs and made to cover chairs and stools. As the demand for carpets increased in the 18th century, factories were established at Paddington, Fulham, and Moorfields, near London, and at Exeter and Axminster in Devon. Axminster worked on well into the 19th century, when it merged with the Wilton Royal Carpet Factory Ltd. at Wilton, Wiltshire, which still operates. The industry dwindled and almost disappeared with the advent of mechanization until about 1880. The craft was revived by the English artist and poet William Morris. Later in the 19th century, a factory opened in Donegal, Ireland; and during the 20th century, many small rugs have been knotted by handicraft societies.

Axminster carpets

Scandinavia. Scandinavian work is similar in concept despite national differences of colour and motif. Abundant

Figure 91: Chinese wool Pillar carpet, late 19th century. When the rug is placed around a pillar, the dragon becomes continuous, and the animal masks at the top form a capital. Chinese cloud motifs and Buddhist symbols cover the field. At the base, a mountain rises from ocean waves. In the Textile Museum, Washington, D.C. 2.41 × 1.23 m.

Figure 92: Savonnerie wool carpet made at Chaillot, France, 17th century. A predominately floral arabesque design covers the field, at either end of which are medallions with landscape scenes. The centre motif is a Baroque cartouche. In the collection of Mr. and Mrs. Charles B. Wrightsman, 3.0 × 9.1 m.

Collection of Mr and Mrs Charles B Wrightsman, photograph the Metropolitan Museum of Art, New York

handmade products include floor coverings, coverlets, and upholstery for benches, chairs, stools, and pillows. Techniques dating from the Vikings (and probably imported by them from Turkey) are continued in Swedish and Finnish rugs, called Rya rugs. Knotted work includes pieces with pile on either side, many Ghiordes on three warps, and braided and woven patchwork carpets with interwoven strips. Geometric designs, rooted in the native arts, are common, appearing, for example, in opulent "wedding carpets." Design was also influenced by Dutch tapestry flower motifs.

Eastern Europe. Knotted Mazovian rugs of East Prussia show the strongest Oriental influence, though at the same time they are deeply rooted in peasant traditions. Many other textiles untouched by west European influence, however, came from southeast Poland, the Ukraine, and southern Russia; some are characterized by ancient textile motifs (such as simple stripes) and forceful colour harmonies, others by geometric designs resembling those of the Orient. *Kilims*, or tapestry-woven carpets, are common in those areas, as they are in the Balkans. In Romania, government promotion and the interest taken by contemporary artists in folk idiom have stimulated modern production during the 20th century.

European folk carpets. Carpet making is so widespread in European folk art that it probably would have developed even without stimulus from the Orient. The most varied techniques are represented in these tradition-bound products the designs of which remained unchanged for generations. The work includes floor coverings, chest covers and bedcovers, and draperies, most of modest size (or pieced together) and many made in sets. The colour scheme is very limited, for even the raw materials were homemade. Machine-made carpets in the later 19th century quickly engulfed home products, but a conscious revival and renewal followed in the 20th century.

North America. The technique of knotting has not been used by the Indians, but many tribes have been making flat-woven floor rugs and blankets since the earliest days of their known history. Before sheep were introduced in the 16th century and wool became dominant, the principal material was cotton, together with various fibres and dog's hair. Indian designs are traditionally abstract, making much use of stripes and a zigzag, or "lightning," motif. The colours are black, white, yellow, blue, tan, and red, the latter often dominant. Among the most skillful carpet makers are the Pueblo and Navaho tribes.

North American Indian rugs

Rugs were made by the colonists in a variety of techniques: knitting; crocheting; braiding thin strips of material into small squares and then sewing them together; and embroidering on a coarse-woven foundation. Hooking (drawing material through a canvas foundation) began around the turn of the 18th century and became very popular; early examples have crude floral, geometric, or animal designs and are very colourful. No knotted carpets were manufactured by the early settlers. In 1884, however, a factory established in Milwaukee (and later moved to New York City) began to weave carpets in traditional European designs. During the 1890s a branch of the English Wilton Royal Carpet Factory made Axminsters at Elizabethport, New Jersey; and a few beautiful, flat-woven carpets in French Baroque and Neoclassical designs were produced around the turn of the century by a tapestry factory in Williams Bridge, New York. After this, machine weaving, which began in the United States in the late 1700s, gradually displaced hand weaving. (Ed.)

TAPESTRY

Historically almost any heavy material, handwoven, machine woven, or even embroidered, used to cover furniture, walls, or floors or for the decoration of clothing, has been called tapestry in popular usage. Since the 18th and 19th centuries, however, the technical definition of tapestry has been narrowed to include only heavy, reversible, patterned or figured handwoven textiles, usually in the form of hangings or upholstery fabric. Tapestry traditionally has been a luxury art afforded only by the wealthy, and even in the 20th century large-scale handwoven tapestries are too expensive for those with moderate incomes.

Tapestry sets

Tapestries are usually designed as single panels or sets. A tapestry set is a group of individual panels related by subject, style, and workmanship and intended to be hung together. The number of pieces in a set varies according to the dimensions of the walls to be covered. The designing of sets was especially common in Europe from the Middle Ages to the 19th century. A 17th-century set, the "Life of Louis XIV," designed by the king's painter Charles Le Brun, included 14 tapestries and two supplementary panels. The number of pieces in 20th-century sets is considerably smaller. "Polynesia," designed by the modern French painter Henri Matisse, for example, has only two pieces, and "Mont-Saint-Michel," woven from a cartoon by the contemporary engraver and sculptor Henri-Georges Adam, is a triptych (three panels). Until the 19th century, tapestries were often ordered in Europe by the "room" rather than by the single panel. A "room" order included

not only wall hangings but also tapestry weavings to upholster furniture, cover cushions, and make bed canopies and other items. Most Western tapestry, however, has been used as a type of movable monumental decoration for large architectural surfaces, though in the 18th century, tapestries were frequently encased in the woodwork.

In the West, tapestry traditionally has been a collective art combining the talents of the painter, or designer, with those of the weaver. The earliest European tapestries, those woven in the Middle Ages, were made by weavers who exercised much of their own ingenuity in following the cartoon, or artist's sketch for the design.

Though he followed the painter's directions and pattern fairly closely, the weaver did not hesitate to make departures from them and assert his own skills and artistic personality. In the Renaissance, tapestries increasingly became woven reproductions of paintings, and the weaver was no longer regarded as the painter's collaborator but became his imitator. In medieval France and Belgium, as well as now, a painter's work was always executed in tapestry through the intermediary of the weaver. Tapestry woven directly by the painter who created it remains an exception, almost exclusive to ladies' handiwork. This section covers the materials, techniques, and history of tapestry making.

Materials

Wool has been the material most widely used for making the warp, or the parallel series of threads that run lengthwise in the fabric of the tapestry. The width-running, weft, or filling threads, which are passed at right angles above and below the warp threads, thereby completely covering them, are also most commonly of wool. The advantages of wool in the weaving of tapestries have been its availability, workability, durability, and the fact that it can be easily dyed to obtain a wide range of colours. Wool has often been used in combination with linen, silk, or cotton threads for the weft. These materials make possible greater variety and contrast of colour and texture and are better suited than wool to detail weaving or to creating delicate effects. In European tapestry, light-coloured silks were used to create pictorial effects of tonal gradation and spatial recession. The sheen of silk thread was often used for highlights or to give a luminous effect when contrasted to the dull and darkly coloured heavier woollen threads. In 18th-century European tapestries, silk was increasingly used, especially at the Beauvais factory in France, to achieve subtle tonal effects. Most of the Chinese and Japanese tapestries have both warp and weft threads of silk. Pure silk tapestries were also made in the Middle Ages by the Byzantines and in parts of the Middle East. Wholly linen tapestries were made in ancient Egypt, while Copts, or Egyptian Christians, and medieval Europeans sometimes used linen for the warp. Cotton and wool were employed for pre-Columbian Peruvian tapestries as well as for some of the tapestries made in the Islāmic world during the Middle Ages. Since the 14th century, European weavers have used gold and silver weft threads along with wool and silk to obtain a sumptuous effect. These threads were made of plain or gilded silver threads wound in a spiral on a silk thread.

Techniques

Tapestry is first of all a technique. It differs from other forms of patterned weaving in that no weft threads are carried the full width of the fabric web, except by an occasional accident of design. Each unit of the pattern or the background is woven with a weft, or thread of the required colour, that is inserted back and forth only over the section where that colour appears in the design or cartoon. As in the weaving of plain cloth, the weft threads pass over and under the warp threads alternately and on the return go under where before it was over and vice versa. Each passage is called a pick, and when completed the wefts are pushed tightly together by various devices (awl, reed, batten, comb, or serrated fingernails in Japan). The weft threads so outnumber the warps that they conceal them completely. The warps in a finished tapestry appear only as more or less marked parallel ridges in the texture, or grain of the fabric, according to their coarseness or fineness.

Weaving tapestry

The thickness of the warp influences the thickness of the tapestry fabric. In Europe during the Middle Ages, the thickness of the wool tapestry fabric in such works as the 14th-century "Angers Apocalypse" tapestry was about 10 to 12 threads to the inch (five to the centimetre). By the 16th century the tapestry grain had gradually become finer as tapestry more closely imitated painting. Known for the regularity and distinctness of its tapestries, the royal French tapestry factory in Paris known as the Gobelins used 15 to 18 threads per inch (six to seven per centimetre) in the 17th century and 18 to 20 (seven to eight) in the 18th century. Another royal factory of the French monarchy at Beauvais had as many as 25 or even 40 threads

Figure 93: *Weaving on a high-warp loom.*
(Left) Weaver indicating an area on the cartoon that corresponds to the portion of the tapestry (right foreground) he has woven. (Right) Weaver, working on the reverse side of the tapestry, pulls a set of warps forward and passes the bobbin behind it. (Photographs taken at the Gobelins factory, France.)

per inch (10 to 16 per centimetre) in the 19th century. These excessively fine grains make the fabric very flat and regular, tending to imitate the canvas of a painting. The grain of 20th-century tapestry approximates that used in 14th- and 15th-century tapestry. The Gobelins factory, for instance, uses 12 or 15 threads per inch (five or six per centimetre).

In many 20th-century tapestries a finer grain is contrasted with the effects of a heavier weave. The grain of silk tapestries, of course, is much finer than those made of wool. It is not uncommon for the silk tapestries of China to have as many as 60 warp threads per inch (about 24 per centimetre).

Where the weft margin of a colour area is straight and parallel to the warps, it forms a kind of slit, or *relais*, which may be treated in any of five different ways. First, it may simply be left open, as in Chinese silk tapestries, which are called *k'o-ssu* (cut silk) for that reason. Second, it may be left open on the loom but sewed up afterward, as in European tapestries from the 14th to the 17th centuries and also in some later types. Third, the weaver may dovetail his wefts, passing from one side and from the other in turn over a common warp. This may be either "comb" dovetailing—single wefts alternating—or "sawtooth" dovetailing—clusters first from one side, next from the other. Dovetailing has the double disadvantage of making the fabric heavier at that point and of blurring the outline. Persian weavers of the 16th century developed a successful variant in silk tapestry rugs whereby a black outline weft was dovetailed over two warps—one of each of the adjacent colour areas—effectively hiding the coloured wefts in the compacting of the weave and providing a strong clear image. The same device is found in pre-Columbian Peru.

The fourth treatment—interlocking—was introduced in the Gobelins factory in the 18th century. Here wefts of juxtaposed colour segments are looped through each other between the two warps that mark, respectively, the margin of each colour. This technique produces a continuous surface of even weight that was prized by the French weavers because the resultant effect more closely approximated that of painting.

A curious variant of these weaving techniques is achieved when between every two rows of wefts there is a weft that runs the full width of the tapestry, thereby making the fabric solid. This technique, if strictly classified, would be called brocade weaving, but the principle is that of tapestry, with the cloth insert subordinate. Rarely used, the technique was employed in Japan in the 7th and 8th centuries, in eastern Persia in the 10th century, and in pre-Columbian Peru.

Twill technique of weaving

Instead of the plain-cloth method of weaving usually used in making tapestries, a twill technique can be used. In this type of weave the weft is floated over two or more warps, then under one or more warps, with this underpassage shifting always one to the right or left, thereby making a diagonal ribbing. As far as can be determined, this technique first appeared in medieval Persia and from the 17th century on was especially used in the Iranian provinces of Khorāsān and Kermān to make shawls of goat's hair or wool. It is also used to make the famed Kashmir shawls and, along with many other crafts, was probably introduced into Kashmir from Persia, in the 16th century. In contemporary European tapestries this technique, usually called eccentric weaving, occasionally has been used in making some of the experimental abstract hangings of the later 20th century.

European tapestry may be woven on either a vertical loom (high-warp, or *haute-lisse* in French) or a horizontal loom (low-warp, or *basse-lisse*). In early high-warp looms the warps were attached to a beam at the top, and groups of warp threads were weighted at the bottom. The weft was beaten up (*i.e.*, pushed) toward the top as the weaving progressed. High-warp looms of this type are pictured on ancient Greek vases. In later high-warp looms the vertical frame has heavy uprights holding a horizontal roller at top and bottom, on which the warps are stretched. Each warp passes through a loop of cord (the *lisses*), and the loops encircling the warps that correspond to uneven numbers are fastened to one slender cylinder; those to the even-numbered warps are fastened to another cylinder. Both cylinders are above the weaver but within reach so that he can pull forward first with one, then with the other set of warps (*i.e.*, form the shed) in order to pass his bobbin behind them. The bobbin (broche) is a short, pointed, slim cylinder of polished wood on which the weft yarn is wound (Figure 93).

The low-warp loom, on the other hand, has the rollers on the same level at table height so that the warps stretched between them are horizontal. To leave the weaver's hands free, the warps are attached to two slats, or poles, each of which is connected with a treadle so that the weaver's foot depresses the odd-numbered or even-numbered series of warps to form a passageway for the bobbin, called a shuttle on the low-warp loom. The cylinders in both instances serve to roll up the finished portion and unroll a further length of unwoven warps so that the section in process is always taut and in a convenient relation to the weaver (Figure 94). At both types of loom the weaver works from the back side, that is, he weaves the tapestry on the wrong side. He has, however, a hand mirror, which he puts through the unwoven warps holding it to reflect the right

Figure 94: *Weaving on a low-warp loom.*
(Left) Weaver depresses the treadles with his feet, thereby controlling the space between warps through which the shuttle, held in his right hand, will be moved. (Right) Working on the reverse side of the tapestry with the cartoon positioned under the warps, the weaver passes the shuttle between the warps. (Photographs taken at the Beauvais factory, France.)

side of the portion in process. While the high-warp weaver can examine his finished work directly by walking around to the other side of his loom, the low-warp worker has to tilt up his frame.

Of the two techniques, low-warp is more commonly used. Of the great European tapestry works only one, Gobelins, has traditionally used high-warp looms. Several weavers can work simultaneously on either kind of loom. Depending on the complexity of the design and the grain or thickness of the tapestry texture, a 20th-century weaver at the Gobelins can produce 32 to 75 square feet (three to seven square metres) a year.

The medieval cartoon

In Western tapestry the medieval cartoon, or preparatory drawing, was usually traced and coloured by a painter on a canvas the size of the tapestry to be woven. At the end of the 15th century the weaver probably wove directly from a model, such as a painting, and consequently copied not a diagrammatic pattern but the original finished work of the painter. At the beginning of the 17th century there arose a clear distinction between the model and the cartoon. The model was the original reference on which the cartoon was based. Cartoons were rapidly and freely used and were often copied.

More than one tapestry can be woven from a cartoon. At the Gobelins factory, for instance, the 17th-century "Indies" tapestry set was woven eight times, remade, and slightly altered by the late Baroque painter François Desportes (1661–1743); these cartoons were woven several more times during the 18th century.

The border of a cartoon tended to be redesigned every time it was commissioned, since each patron would have a different heraldic device or personal preference for ornamental motifs. Borders were frequently designed by an artist different from the one who conceived the cartoon for the central narrative or principal image. As an element of tapestry design, however, borders or frames were important in European tapestry only from the 16th to the 19th century. Medieval and 20th-century tapestries seldom use this device, which emphasizes the idea of the tapestry as a reproduction of or substitution for a painting.

Contemporary cartoons

A fully painted cartoon requires much of the painter's time and is tedious to make. In the 20th century, therefore, other solutions have been adopted. The cartoon may be a photographic enlargement of a fully painted model or, more simply, a numbered diagrammatic drawing. The latter type of cartoon was worked out by the famous French tapestry designer Jean Lurçat during World War II. In this method each number corresponds to a precise colour and each cartoonist has his own range of colours. The colours are not indicated in a photographic enlargement, but the weaver refers to a small colour model provided by the painter and from it makes a selection of wool samples.

The high-warp weaver has the full-size cartoon, which he follows as it hangs beside or behind him. The low-warp worker has the cartoon laid under the warps, so he follows it from immediately above. In both cases the main outlines are drawn with ink on the warps after they have been mounted, or attached to the loom. The design is executed, in all European work since the Middle Ages, at right angles to the loom, so that in the finished hanging the warps usually run horizontally rather than vertically as they ran on the loom. Though in certain pieces the warps run vertically, it is aesthetically advantageous for the tapestries to be executed horizontally, since the warp ribbing tends to create a texture more or less reinforced by linear shadows, which, if vertical, sever the design but if horizontal bind it into continuity. Practically, however, horizontal warps are disadvantageous, since the horizontal slits made in weaving will pull apart more rapidly than vertical slits because of the weight of the hanging.

Periods and centres of activity

ANCIENT WESTERN WORLD

Examples of tapestry weaving from the ancient world are so isolated and fragmentary as to make it uncertain either when or where the art originated. The earliest known tapestry weaving was done in linen by the ancient Egyptians between 1483 and 1411 BC. Preserved by the dry desert climate of Egypt, three tapestry fragments were found in the tomb of Thutmose IV. Two of the fragments have cartouches of Egyptian pharaohs, and the third is a series of hieroglyphs. In the tomb of Tutankhamen (*c.* 1323 BC), a robe and glove woven by the tapestry technique have also been found.

Although no examples remain, writers of antiquity are unanimous in proclaiming the magnificence of Babylonian and Assyrian tapestries. Some scholars have speculated that the ancient Egyptians learned the art of tapestry from the ancient peoples of Mesopotamia. During that period when the few preserved Egyptian tapestry fragments were made, Mesopotamian ideas, techniques, and, perhaps, craftsmen were entering Egypt. These scholars conjecture that, since tapestry weaving did not occur in quantity again in Egypt until the 4th century AD, it is likely that the craft was not indigenous.

Tapestry weaving continued to flourish in western Asia in the 1st millennium before Christ. Fragments of wool tapestries dating from the 4th or 3rd century BC have been found in graves in Ukraine near Kerch in the Crimean peninsula. The ornamental motifs of these fragments are of a widely diffused Hellenistic style that was especially prevalent in Syrian art at the time. Another fragment showing close Syrian connections is a piece of silk tapestry dating about 200 to 500 years later and found in China at Lou-lan in Sinkiang Uighur Autonomous Region. Other fragments have been found in Syria at the archaeological sites of Palmyra and Doura-Europus. If climatic conditions for textile preservation in the Middle East had been more favourable, it might be possible to theorize that Syria was a great centre of tapestry weaving, especially at the start of the Christian Era.

Tapestry in ancient Greece and Rome

There are literary descriptions of the making of tapestry in ancient Greece and Rome. In the *Odyssey,* Homer (8th century BC?) describes Penelope working on a tapestry that was unravelled each night as she waited for Odysseus. The Roman poet Ovid (43 BC–AD 17) in the *Metamorphoses* describes the tapestry looms used by Minerva and Arachne in their mythological weaving contest. During the period of the empire the Romans apparently imported a considerable number of the tapestries used in their public buildings as well as in the homes of the wealthy. Since the Latin terms referring to tapestry and weaving are Greek in origin, it is generally supposed that the art of tapestry making was taught to the Romans by the Greeks.

EASTERN ASIA

Called *k'o-ssu* (cut silk), tapestry has long been produced in China, traditionally being made entirely of silk; Chinese tapestries are extremely fine in texture and light in weight. The weave is finished perfectly on both sides so

that the tapestries are reversible. The warps are vertical in relation to the pattern, rather than horizontal as in European weaving. Sometimes the weaver uses metal threads to make his hangings more sumptuous or highlights the design by painting, although this is not considered a commendable expedient.

Many *k'o-ssu*, such as "T'ung Fung Stealing the Peaches of Longevity" (Figure 95), imitated paintings and were mounted on scrolls or album leaves in the same manner as the pictures they copied. Tapestries to cover large wall surfaces, such as the *k'o-ssu* (seven feet three inches by five feet nine inches; 2.2 by 1.75 metres) of "Feng-huang in a Rock Garden" (late Ming period, Metropolitan Museum of Art, New York), were usually brighter in colour, heavier in texture, and frequently woven with metal threads. Tapestry was also used to decorate furniture and clothing.

Early Chinese *k'o-ssu*

The earliest surviving examples of *k'o-ssu* date from the T'ang dynasty (AD 618–907). Eighth-century remains have been found in desert oases around Turfan in the Sinkiang Uighur Autonomous Region of China, and late T'ang fragments have been found in the Caves of the Thousand Buddhas (Ch'ien-fo-tung or Mo-kao-k'u) near the town of Tun-Huang in Kansu Province. It is thought that these weavings are probably not representative of the more fully developed *k'o-ssu* of the T'ang period because they show only simple repeating patterns of flowers, vines, ducks, lions, etc., and were found in relatively remote areas of Central Asia along the silk-trade route. In comparison is the more sophisticated 8th-century *k'o-ssu* that hangs in the Taima-dera, a temple near Nara, Japan. Based on the story of the T'ang dynasty priest Shan-tao, this 43-square-foot (four-square-metre) weaving is the oldest known complete Chinese wall tapestry.

During the Sung dynasty (960–1279) the imperial family encouraged painting and patronized the art of tapestry. An important weaving centre was at Ting-chou in Hopeh Province. Under the Yüan dynasty (1206–1368) a government factory for weaving *k'o-ssu* was established at Hangchow (Lin-an) in Chekiang Province. Characterized by their rich ornamental designs, the Hangchow *k'o-ssu* were frequently woven with gold and silver thread. Examples of tapestry from the Ming period (1368–1644) are rare and exquisite. The *k'o-ssu* executed during the K'ang-hsi (1661–1722), or rule of the great Manchu emperor of China, Hsüan-yeh, are the finest tapestries produced during the Ch'ing dynasty (1644–1911/12). They are distinguished for their delicate colouring and the use of philosophical and religious themes. Later Ch'ing *k'o-ssu* has survived in great abundance and shows a decided artistic and technical decline. This is especially evident in the frequent use of painting to perfect design details in 19th-century *k'o-ssu*.

Japanese *tsuzure*

The tapestry technique travelled from China to Japan in the late 15th or early 16th century during the Muromachi (Ashikaga) period (1338–1573). Japanese tapestry called *tsuzure-nishiki* (polychrome tapestry) differs from the Chinese *k'o-ssu* in its more pronounced surface relief. This is achieved through the use of thick cotton weft threads covered with silk, gold, or silver thread.

Paralleling the great period of sumptuous brocade manufacturing, the production of *tsuzure* flourished during the Tokugawa (Edo) period (1603–1867), especially in the early 17th century and throughout the entire 18th century (Figure 95). These polychrome tapestries were primarily used to decorate garments and for wrapping gifts; on rare occasions they were also used as wall hangings. Although the tapestry industry declined in quality in the 19th century, it has been revitalized in the 20th century. Monumental wall hangings and theatre curtains are woven in the textile factories of Ōsaka and Kyōto by both traditional Japanese and European tapestry techniques.

The history of the art in Korea remains obscure. Rather coarse wool tapestry-woven rugs with stylized motifs, however, are still produced there.

PRE-COLUMBIAN AMERICAS

The most skilled weaving in pre-Columbian America was achieved by the Andean Indian cultures of ancient Peru. The origins of tapestry weaving among these peoples are believed to date as early as the beginnings of the Christian Era. By the 6th and 7th centuries the technique of tapestry weaving was established, and a large number of pieces in this medium have survived, particularly from the 8th to the 12th centuries. Most of these tapestry weavings have been found in Peruvian coastal burial sites, where the dry desert climate prevented their deterioration. The dead were buried in clothes that display some of the most varied and skilled techniques of weaving and needlework ever current in any culture. Tapestry weaving was used principally to make garment decorations that were usually integral to the garment fabric. Narrow strips to ornament the edges of clothing were common, as were panels covering the entire surface of the *cuzma*, a poncho-like Indian shirt. Fragments of tapestry wall hangings have also survived.

According to chronicles written by Spanish colonizers and scenes painted on ancient Peruvian pottery, weaving was generally done by women whose great manual skill made up for the simplicity of the looms, which are still used by Indian craftsmen. The workmanship was extremely fine. Certain tapestry fragments have been found with 150 to 250 weft threads per square inch (60 to 100 per square centimetre). The warps of the tapestries are of undyed cotton, being, therefore, either white or brown. The wefts are of wool from the llama, guanaco, alpaca, or vicuña, with cotton sometimes used to obtain bright white. The tapestries are usually polychrome, for the range of available colours made with natural dyes was large. Strong colour contrasts were preferred to the use of subtly graded tones of colours, especially in the Inca period (*c.* 13th to 16th century). Compositions tended to bold conventionalized designs often of human or animal figures and elaborate geometric patterns. Plant motifs are comparatively rare.

Figure 96: Colonial tapestry, late 16th–17th centuries. In the Museum of Fine Arts, Boston. 2.29 × 2.12 m.

After the Spanish conquest, looms from Spain were imported by the viceroyalty of Peru, and the weaving of tapestry was continued during the colonial period. The skilled Inca and later mestizo weavers evolved a curious blending of European influences and Indian traditions.

Tapestry may also have been current in other developed pre-Columbian cultures of Central America and Mexico. Climatic conditions, however, have been destructive to textiles.

MIDDLE AGES IN EGYPT AND THE NEAR EAST

Tapestry weaving was done by the Copts, or Egyptian Christians, from the 3rd to about the 12th century AD. Their tapestries are of great interest not only because of their artistic quality and technical skill but also because

Coptic tapestry

they are a bridge between the art of the ancient world and the art of the Middle Ages in western Europe. Fragments from the 5th to the 7th century are particularly numerous, and the largest number of examples have survived in the Egyptian cemetery sites of Akhmīm, Antinoë, and Saqqārah. As a result of a change in burial customs, perhaps attributable to Romanization and the widespread adoption of Christianity in Egypt, the ancient practice of mummification and its attendant ritual fell into disuse after the 4th century AD. The dead were subsequently buried in daily clothes or were wrapped in discarded wall hangings and tapestries. The clothing was ornamented with tapestry trimming, which was either woven into the fabric or attached to tunics and cloaks. Other burial furnishings included pillows and coverings. Tapestries were also used for the decoration of Christian churches, but few of these wall hangings have survived.

Coptic tapestries were woven with woollen wefts on linen warps, though a few with silk wefts have been preserved. Cotton wefts were occasionally used to obtain a brighter white. Primarily in the 7th century and perhaps also the 8th century, tapestry ornamentation was often supplemented by embroidery, as in border margins. In a special variant, which is not true tapestry, characteristic ornamental motifs such as meanders or other geometric repeats are executed with a free bobbin that follows the design without regard to consistency of weft direction.

Many of the early Coptic tapestries were done in a silhouette technique in which the motif or design was in a single dark colour, usually a tone of purple achieved by dying with madder and indigo, against a lighter background colour. After the 5th century, polychrome tapestries became increasingly common.

Many Coptic tapestry trimmings were woven with indigenous designs. Recurring motifs related to the ancient Egyptian funerary cult of Osiris and included the grape vine or ivy and the wine amphora. These motifs were considered appropriate to burial robes because of their relevance to revival in a life after death. Other favourite subjects were the hunter on horseback, boy-warriors, desert animals (especially the lion and the hare), creatures of mythology, dancing figures, and baskets of fruits and flowers (Figure 97). Christian subjects are as a rule late in date and are

mostly figures of saints, standing or on horseback, against a red background. Depictions of biblical stories are rare. Some of the Coptic designs were copied, in a more or less distorted manner, from those woven into silk textiles imported from Syria.

Islāmic tapestry

After the invasion of Egypt by the Muslims in 640, the quality of Coptic tapestry began to deteriorate, although the industry continued to flourish by adapting itself to the tastes of the conquerors. During the Tūlūnid period (868–905) bands of tapestry trimming in wool or often in silk, occasionally with metal-thread enrichments, were woven into white or dark green linen garments. In the Fātimid period (909–1171) silk tapestry weaving in golden yellow and scarlet became common. The motifs of the Islāmic period of Egyptian weaving were often interlacing geometric patterns frequently enclosing inscriptions or highly stylized small birds, animals, and flowers. Many of these inscriptions merely simulate writing, but many are legible. Giving religious phrases or the names and titles of rulers, they are in handsome angular Kufic scripts on earlier pieces and in cursive scripts later.

From the 6th to the 8th century AD, and doubtless from then on, striking wool tapestries were being made in Syria corresponding in style to the contemporary silk textiles with animals or birds in energetic heraldic stylization, framed in roundels, and almost always on a red ground. Later, from the 11th to the 13th century, highly distinctive silk- and gold-thread tapestries were produced in Syria incorporating pagan motifs from classical antiquity.

Fewer specimens of Persian tapestries have survived, but one notable fragment, now in the Moore Collection at Yale University, bears an ibex in the style of the Sāsānian period (Figure 97). A single piece from the Seljuq period (11th century) established a continuation of the use of the tapestry technique, which reappears in the 16th century (intermediate examples apparently having all been destroyed) as the medium for rich silk- and metal-thread rugs, of which only three are known still to exist (also in the Moore Collection, New Haven, Connecticut), though others are illustrated in Persian miniatures. The modern descendants of these are kilims, or pileless carpets woven by the tapestry technique. Common to the entire Near East, these rugs are especially produced in the Caucasus and Asia Minor, as well as in parts of eastern Europe. Occasionally silk, they are more often wool with simple geometric patterns in bold colours.

EARLY MIDDLE AGES IN WESTERN EUROPE

Numerous documents dating from as early as the end of the 8th century describe tapestries with figurative ornamentation decorating churches and monasteries in western Europe, but no examples remain, and the ambiguity of the terms used to refer to these hangings makes it impossible to be certain of the technique employed. The 11th-century so-called Bayeux Tapestry depicting the Norman Conquest of England, for example, is not a woven tapestry at all but is a crewel-embroidered hanging.

Like the art of stained glass, western European tapestry flourished largely from the beginnings of the Gothic period in the 13th century to the 20th century. Few pre-Gothic tapestries have survived. Perhaps the oldest preserved wall tapestry woven in medieval Europe is the hanging for the choir of the church of St. Gereon at Cologne in Germany. This seven-colour wool tapestry is generally thought to have been made in Cologne in the early 11th century. The medallions with bulls and griffons locked in combat were probably adapted from Byzantine or Syrian silk textiles. The "Cloth of Saint Gereon" is thematically ornamental, but an early series of three tapestries woven in the Rhineland for the Halberstadt Cathedral were narrative. Dating from the late 12th and early 13th centuries, these wool and linen hangings are highly stylized and schematic in their representations of figures and space, with all forms being outlined. The "Tapestry of the Angels," showing scenes from the life of Abraham and St. Michael the Archangel, and the "Tapestry of the Apostles," showing Christ surrounded by his 12 disciples, were both intended to be hung over the cathedral's choir stalls and therefore are long and narrow. The third hanging, called the "Tapestry of Charlemagne Among the Four Philosophers of Antiquity," is a vertical wall hanging related to works produced by the convent at Quedlinburg in the German Rhineland during the Romanesque period of the 12th and early 13th centuries.

Romanesque tapestry

Fragments of a tapestry with traces of human figures and trees reminiscent of hangings described in the Norse sagas were found in an early 9th-century burial ship excavated at Oseborg in Norway. One of the major works of Romanesque weaving is a more complete tapestry dating from around the end of the 12th or early 13th century

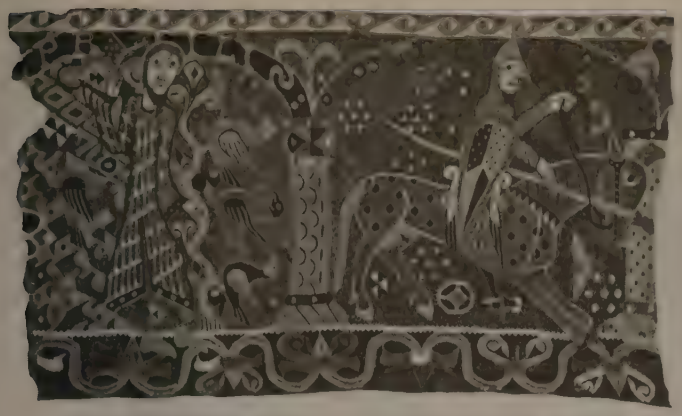

Figure 98: "April and May," fragment known as the "Baldishol Tapestry," after 1190. In the Kunstindustrimuseet, Oslo. 1.18 × 2.00 m.

that was made for the Norwegian church of Baldishol in the district of Hedemark. Originally a set of wool hangings on the 12 months of the year, only the panels of April and May have survived (Figure 98). The pronounced stylization of the images relates these tapestries to those executed for Halberstadt Cathedral.

14TH CENTURY

In the 14th century the western European tradition of tapestry became firmly established. At that time the most sophisticated centres of production were in Paris and Flanders. Large numbers of tapestries are recorded in inventories. The more luxurious standards of living being adopted by the wealthy of the Gothic period extended the use of tapestries beyond the customary wall hangings to covers for furniture. Survivals of 14th-century workmanship, however, are rare, and the most important of these were produced by Parisian weavers. The outstanding example of their art is the famous Angers Apocalypse (Musée des Tapisseries, Angers, France), which was begun in 1377 for the Duke of Anjou by Nicolas Bataille (flourished *c.* 1363–1400). This monumental set originally included seven tapestries, each measuring approximately 16.5 feet in height by 80 feet in length (5.03 by 24.38 metres). Based on cartoons drawn by Jean de Bandol of Bruges (flourished 1368–81), the official painter to Charles V, king of France, only 67 of the original 105 scenes have survived. A slightly later series (*c.* 1385) possibly woven in the same Parisian workshop is the "Nine Heroes" (Metropolitan Museum of Art, The Cloisters, New York). This set is not a religious narrative but illustrates the chivalric text *Histoire des Neuf Preux* ("Story of the Nine Heroes") by the early 14th-century wandering minstrel, or jongleur, Jacques de Longuyon.

Paris tapestry

Flanders, particularly the city of Arras, was the other great centre of the tapestry industry in 14th-century Europe. The tapestry produced there had such an international reputation that terms for tapestry in Italian (*arrazzo*) and Spanish (*drap de raz*) and English (arras) were derived from the name of this Flemish city. Long a medieval centre of textile weaving, Arras became an important tapestry centre when the leading citizens decided to create a luxury industry to alleviate the economic crisis caused by a decline in the sale of Arras textiles due to the popularity of cloth from the Flemish region of Brabant.

15TH CENTURY

Arras tapestry

The greatest tapestries of the 15th century were produced in the Flemish cities of Arras, Tournai, and Brussels. In the first half of the century it was Arras that particularly prospered under the patronage of the dukes of Burgundy. Duke Philip the Good (1396–1467) had a specially designed building erected in the city to allow for better conservation of his tapestry collection. Between 1423 and 1467 no fewer than 59 master tapestry weavers were working in Arras, but following the French siege of the city in 1477 under King Louis XI the industry declined. After approximately 1530 it was no longer active. While the importance of Arras waned, that of Tournai and eventually Brussels waxed—their tapestries becoming the most sought after in the late 15th century. Local identification marks did not become general until the 16th century, and continual intercourse between the various medieval centres of tapestry making, particularly Arras and Tournai, adds to the difficulty of determining where individual tapestries were made. Despite the prestige of Arras workmanship, it is ironic that only one set of tapestries dating from 1402 is inscribed with the actual name. Large fragments showing scenes from the lives of St. Piat and St. Eleutherius survive in the cathedral of Tournai, for which they were commissioned. The imagery of these tapestries, like that of most Gothic hangings, was closely related to the styles of painting current at the time. Other important examples of supposed Arras tapestries inspired by Franco-Flemish book miniatures or paintings on wood panels include the early 15th-century tapestry of "The Annunciation" (Metropolitan Museum of Art, New York), which was probably woven after a cartoon by Melchior Broederlam (active 1381–*c.* 1409), and the "Court Scenes" (Musée des Arts Décoratifs, Paris), related to the *Très Riches Heures du duc de Berry* illuminated by the brothers Limburg (active early 15th century).

Whether a tapestry is an Arras or not is usually determined by comparison with the "History of St. Piat and St. Eleuthère." One of the finest works so attributed is the early 14th-century fragment from the set in the Museo Civico at Padua, Italy, illustrating the *Geste of Jourdain de Blaye,* a medieval chivalric story adapted from the ancient Greco-Roman romance *Apollonius of Tyre.*

Tournai tapestry

The craft, practiced since the end of the 13th century at Tournai, proved so prosperous that in 1398 a regulation concerning production was published. It is the oldest known ordinance regulating the craft of tapestry weaving. Among partially surviving tapestries ordered in the late 15th century by the Court of Burgundy were two sets produced by the weaver and tapestry merchant Pasquier Grenier (died 1493) for Philip the Good. One set, "The Story of Alexander" (Galleria Doria-Pamphili, Rome), was purchased in 1459, and the other, "The Knight of the Swan" (St. Katherine, Kraków, Poland, and Österreichisches Museum für Angewandte Kunst, Vienna), was bought in 1462.

Cited by many scholars as an example of mid-15th-century Tournai weaving under the influence of Arras are the four renowned tapestries of "The Hunts of the Dukes of Devonshire" (Victoria and Albert Museum, London). Typical of the developed late Gothic Tournai style are the compacted vertical compositions of "The Story of Strong King Clovis" (mid-15th century; Musée de l'Oeuvre Notre-Dame, Reims, France) and "The Story of Caesar" (*c.* 1465–70; Historisches Museum, Bern, Switzerland). Many of the attributed Tournai weavings are heavily outlined and have a solemnity that contrasts to the more fanciful nature of Arras weavings. A sense of monumentality is created by the immense size of many of these supposed Tournai weavings and by the way the vast surfaces are densely filled with superimposed imagery.

A producer of tapestry since the 14th century, in the 15th century Brussels vied with Arras and Tournai. By mid-century, Brussels was noted for its highly skilled repro-

Giraudon—Art Resource

ductions of religious paintings by Flemish masters of late Gothic realism, such as in the tapestry of "The Adoration of the Magi" (Figure 99). These panels were called "altarpiece tapestries" because they were usually intended for churches or private chapels, where they either were used as an altar cloth or antependium or were hung behind the altar as an altarpiece or fabric retable. In scale, altarpiece tapestries approximated the dimensions of the painting they copied and were, therefore, much smaller in size than the muralesque wall hangings of Arras and Tournai. Silk was commonly used to obtain the greater degree of naturalistic detail essential in reproducing a painting.

Tapis d'or and millefleurs tapestries

In the late 15th and early 16th centuries, Brussels also became famous for its production of *tapis d'or,* or "golden carpets," so called because of the profuse use of gold threads. Examples such as "The Triumph of Christ," popularly known as the "Mazarin Tapestry" (*c.* 1500; National Gallery of Art, Washington, D.C.), are characterized by their richness of effect.

Perhaps the best known late Gothic hangings were the fanciful tapestries usually referred to as millefleurs ("thousand flowers"). A red or dark-blue ground strewn with flora and fauna sometimes serves as a setting for heraldic devices such as in the late 15th-century tapestry with the coat of arms of Philip the Good (Historisches Museum, Bern, Switzerland) or acts as a background for scenes of the chivalric aristocratic life during the late Middle Ages, such as in "The Hunt of the Unicorn" (Metropolitan Museum of Art, The Cloisters, New York) or "The Lady with the Unicorn" (Musée de Cluny, Paris). The origin of millefleurs tapestries is disputed, but it is thought that they were woven in the Flemish workshops of Brussels and Bruges and by itinerant weavers in the Loire Valley of France.

Itinerant Flemish and French weavers, setting up their looms in cities where there was temporary employment, carried tapestry weaving to Italy as early as the 15th century. Before the 16th century, however, most tapestries were bought in France and Flanders. Small workshops attached to the courts of various Italian nobles sporadically appeared for brief periods in Siena, Brescia, Todi, Perugia, Urbino, Mantua, Modena, Genoa, and Ferrara. The only one of importance was the Flemish-directed workshop of Ferrara, established around 1445 by the duke Lionello d'Este, who commissioned the famous Ferrarese early Renaissance painter Cosmè Tura (*c.* 1430–95) to make cartoons for his weavers.

16TH CENTURY

Two new trends became apparent in the 16th century. The first, brought about by war and persecution in Flanders, resulted in the widespread diffusion of the Flemish art of tapestry weaving. Many Flemish artisans in the 16th century were forced to become refugees. Some grouped together to live the life of travelling craftsmen, while others attempted to reestablish their trade abroad. Flemish weavers were welcomed everywhere as carriers of a great tradition. Such itinerant masters established shops from England to Italy. The second important new trend emanated from Italy and reflected the superiority attached by the Italian Renaissance to the art of painting. The decisive step, which was to bring about the subordination of weaving to painting for more than 400 years in the art of tapestry, was taken when Pope Leo X commissioned the famed weaver Pieter van Aelst (flourished late 15th–early 16th century) of Brussels to make a series of tapestries illustrating the "Acts of the Apostles" from cartoons produced between 1514 and 1516 by Raphael (1483–1520). Little or no concession had been made to the tapestry medium for which the cartoons were intended, but the tapestries were a great success, and numerous copies of them were subsequently made.

The ascendancy of Brussels tapestry

The occupation of Arras by the French in the late 15th century and successive sieges of Tournai in the early 16th century contributed to the rise of Brussels as the leading tapestry centre of Flanders—a position it maintained until the 17th century. The patronage of the papacy and the imperial houses of Spain and Austria, along with other European royalty and the skill of its weavers, who were among the finest in Europe, combined to establish the international reputation of Brussels tapestry. The industry was controlled by a monopoly of rich merchants. Tapestry making proved so prosperous in the period between 1510 and the outbreak of the Peasants' War in 1568 that the industry had to be protected by regulations against frauds and forgeries. A number of communal ordinances followed one another in rapid succession, the most important being that of 1528, requiring each tapestry woven in Brussels to bear the mark of the city—a flat red shield flanked by two *B*'s standing for Brussels and the province of Brabant. The same imperial edict issued by Emperor Charles V also required manufacturers and merchants to use the signature or monogram of the master weaver or workshop.

Work of van Orley

It is the designs of the Flemish painter Bernard van Orley (1492?–1541) that are most characteristic of the Renaissance style of Brussels tapestry. Van Orley attempted to reconcile the traditions of late Gothic northern realism and the monumentality and idealism of Italian Renaissance art with the artistic potential of the tapestry medium. His earlier works, such as "The Legend of Our Lady of Le Sablon" (Musées Royaux d'Art et d'Histoire, Brussels) and "The Revelation of St. John" (1520–30; Patrimonio Nacional, Spain), still show compositional elements that link them to medieval Flemish art. Later, his work was influenced by the cartoons of Italian artists that were woven in Brussels workshops, such as Raphael's "Act of the Apostles" and the designs for "The Story of Scipio" and "Fructus Belli," executed by Raphael's disciple, the Mannerist painter and architect Giulio Romano (1499–1546). Van Orley adapted the Italians' preference for monumentality and their feeling for depth and sculptural modelling to Flemish tastes and traditions for genre and naturalistic detail in sets such as "The Battle of Pavia" (Museo e Gallerie Nazionali di Capodimonte, Naples), "The Story of Abraham" (Madrid and Vienna), "The Story of Tobias" (Vienna), and "The Hunts of the Emperor Maximilian I" (before 1528; Louvre, Paris). Among his followers in the first half of the 16th century were the Flemish painters Pieter Coecke van Aelst (1502–50), Jan Vermeyen (*c.* 1500–59), and Michel Coxcie (1499–1592). It was not only the cartoonists of Brussels who achieved international reputations but also the weavers of the early 15th century. Among the best known are Pieter van Aelst, Pieter and Willem Pannemaker, and Frans (active *c.* 1540–90) and Jacob Geubels (active *c.* 1580–1605).

Other limited centres of tapestry making in 16th-century Flanders were Antwerp, Bruges, Enghien, Oudenaarde, Grammont, Alost, Lille, and Tournai. Perhaps the most distinctive type of tapestry produced in these cities was the *verdures* of Enghien and Oudenaarde. French tapestry weaving, after its eclipse in the 15th century when nomadic weavers seem to have been more active than established shops, owes much of its eventual prestige to an unusual degree of royal patronage. This resulted in the 17th century in the foundation of the Gobelins and Beauvais state factories, the names of which have now become household words. A prelude to this development was the factory established by Francis I in 1538 near Paris

at the château of Fontainebleau to make tapestries for his royal residences. Staffed by Flemish weavers, the cartoons were largely furnished by two Italian Mannerist artists, Francesco Primaticcio (1504–70) and Rosso Fiorentino (1494–1540), who were court painters to the King. The six tapestries (Kunsthistorisches Museum, Vienna), based on their murals for the Galerie des Réformes in the château, are the first tapestries in which sculpture as well as painting is imitated in the highly illusionistic manner of a trompe-l'oeil (fool-the-eye) effect (Figure 100).

French trompe-l'oeil tapestries

The Fontainebleau workshop, which was active for only 12 years, provided the springboard for subsequent developments in Paris, where in 1551 Henry II established and endowed with special privileges the Hôpital de la Trinité factory.

In the first third of the 16th century, Franco-Flemish weavers and small court workshops continued to supply the only indigenous Italian tapestry. Weaving was done in Genoa, Verona, Venice, Milan, and Mantua. The first internationally important Italian tapestry factory was established in 1536 in Ferrara by Duke Ercole II of the House of Este. The Arrazeria Medicea founded in 1546 in Florence by the Medici grand duke Cosimo I (1519–74) was the most important tapestry factory instituted in Italy during the 16th century and survived into the early 18th century. It was headed initially by the famous mid-15th-century Flemish weavers Nicolas Karcher and Jan van der Roost, both of whom had worked in the Ferrara workshop of Duke Ercole II.

Cartoons were designed by such leading Mannerist artists of Florence as Jacopo Pontormo (1494–1556/57), Francesco Salviati (1510–63), Il Bronzino (1503–72), and Bachiacca (1494–1557), who designed the "Grotesques" (*c.* 1550; Uffizi, Florence), one of the most famous and influential tapestry sets produced by the Arrazeria Medicea.

The major textile art in medieval England was embroidery. When woven tapestries were needed, they were imported from Flanders. Although occasional references to Arras weavers in England date from the 13th century and a few indigenous armorial tapestries have survived from the 15th century, it was only after the middle of the 16th century that the English organized tapestry works. The first important workshops were set up in Bercheston (Warwickshire) by a wealthy squire, William Sheldon (died 1570). They initially produced cushion covers and small hangings of heraldic and ornamental subjects. A later specialty of these shops was a series of topographic tapestries. Woven in 1588 from contemporary maps of the Midland counties, these tapestries featured bird's-eye views of hills, trees, and towns, surrounded, according to the custom of the period, by Flemish-styled borders of architectural and figural ornament (Figure 101, right). Many of the men who worked in these shops were Flemings who had fled the mid-16th-century religious persecutions in the Lowlands.

German court factories

Germany was one of the first regions to receive Flemish weavers fleeing religious persecution in the Lowlands. Their small workshops prospered in such cities as Cologne, Hamburg, Kassel, Leipzig, Torgau, Lüneburg, Frankenthal, and Stuttgart. Most of the works produced were in the Flemish style. In Switzerland, on the other hand, where tapestry making had flourished in the 14th and 15th centuries, the industry almost ceased to exist except around Basel and Lucerne.

17TH AND 18TH CENTURIES

It was due to the initiative of Henry IV, whose planning of his nation's economy emphasized the luxury production that has since been commercially important in France, that decisive steps were taken in establishing a French tapestry industry. In 1608 Henry gave official recognition to the French workshop (using the high-warp method) of Girard Laurent and Dubout by establishing them in the Louvre, and at the same time he encouraged the immigration of Flemish weavers practicing the low-warp method who would help Paris to compete with the flourishing industries of Brussels and Antwerp.

At the turn of the 16th–17th centuries, two Flemish weavers had been taken to France by government arrangement to establish low-warp looms in Paris: François de La Planche (or Franz van den Planken; 1573–1627) and Marc de Comans (1563–before 1650). Satisfactory working conditions were found for them in the old Gobelins family dyeworks on the outskirts of the city, and so began the establishment commonly known by that name that has lasted ever since. One of its first ambitious productions was an allegorical invention lauding Catherine de Médicis under the guise of Artemisia. The cartoons for this set were chiefly by the French Mannerist painter Antoine Caron (*c.* 1515–93). The Baroque verve and vitality of the Flemish painter Peter Paul Rubens (1577–1640) and Simon Vouet (1590–1649) brought new life to French designs in the early 17th century.

De La Planche died in 1627 and was succeeded by his son, who broke with the Comans family and moved to the Faubourg Saint-German-des-Près, leaving the Comans at the Gobelins. Competition became bitter, but both continued to produce a considerable quantity, as well as good quality, until they were superseded in 1662 by the royal factory, which purchased the Gobelins works at its location.

Establishment of the Gobelins factory

The Gobelins was officially established in 1667, receiving the title Manufacture Royale des Meubles de la Couronne ("Royal Factory of Furnishings to the Crown"). Initially it included all the king's artisan corps (tapestry weavers, cabinetmakers, goldsmiths and silversmiths, etc.) that produced furnishings for the royal residences, especially the

château of Versailles. Louis XIV's finance minister, Jean-Baptiste Colbert (1619–83), always alert to profitable opportunities, recruited skilled personnel not only from the de La Planche and Comans shops but also from the old Louvre enterprise and thus established a new tapestry works with both high- and low-warp looms. The Gobelins' first director was the painter Charles Le Brun (1619–90), who had managed the short-lived royal tapestry works established in 1658 by Colbert's predecessor, Nicolas Fouquet (1615–80), at his château of Vaux-le-Vicomte near Paris. Le Brun applied himself with prodigious energy to his new position and proved to have a special talent for the task of celebrating the glory of Louis XIV. Among the most important sets he designed were "The Elements," "The Seasons," "The Child Gardeners," "The Story of Alexander," and, above all, the "Life of Louis XIV" and the "Royal Residences" (most of these sets are in the possession of Mobilier National in Paris).

When Le Brun died, the painter Pierre Mignard (1612–95) became director. The draining of the royal treasury closed the Gobelins in 1694. The factory opened again in 1699, when a lighter spirit was introduced into tapestry design by the decorative inventions, especially grotesques, of Claude Audran III (1658–1734), who designed such sets as "The Grotesque Months" and "The Portières of the Gods." Louis XV (1710–74), in his turn, was celebrated in a set of "Hunts" by the Rococo painter Jean-Baptiste Oudry (1686–1755). Oudry was director of the Gobelins from 1733 until his death in 1755, when he was succeeded by François Boucher (1703–70), the outstanding artist-director of the 18th century. Boucher and Charles-Antoine Coypel (1694–1752), a Rococo painter, designed

Alentours tapestry

many of the popular *alentours* tapestries, in which the central subject, presented as a painting bordered by a frame simulating gilded wood, is eclipsed by the rich use of ornamental devices surrounding it. Boucher's "Loves of the Gods" were also *alentours* and enjoyed a great success and popularity, especially among the English nobility. "The Story of Don Quixote" (Mobilier National, Paris) was designed by Coypel and woven nine times between 1714 and 1794.

Oudry's sophistication and polished elegance posed new problems for the weavers. Now indeed it was necessary for them to learn to paint with a bobbin, and to this end hundreds of new dyes were perfected for both wool and silk, until about 10,000 hues were available, to effect almost imperceptible tonal modulations; and interlocking of the wefts was introduced to render the transitions practically invisible, while the finest textures practical were used.

The Gobelins succeeded in surviving the French Revolution. Napoleon as emperor, like Louis XIV, desired an art of apotheosis and ordered a set of tapestries (1809–15; Mobilier National, Paris) that were devoted to his reign. Paintings by such French Neoclassical painters as Jacques-Louis David (1748–1825), Carle Vernet (1758–1836), and Anne-Louis Girodet-Trioson (1767–1824) were woven into tapestries in the late 18th and early 19th centuries.

The Beauvais factory

Another major state-subsidized factory established in 1664 at Beauvais had been carried on by two Flemings, Louis Hinart for 20 years and Philippe Behagle for 27 more. It was administered in much the same way as the Gobelins. Beauvais, however, was a private enterprise with royal patronage intended to produce tapestries for the nobility and the rich bourgeoisie, while Gobelins' work was only for the king.

Two types of decorative panels were particularly developed at Beauvais in the late 17th century, the architectural composition and the grotesque. The former, such as in the set of "Marine Triumphs" (1690; Banque de France, Paris), usually shows a complex fantasy architecture reminiscent of Baroque stage sets. In the latter, architectural tracery defines a complex of panels, framing a medley of festoons, scarves, vases, musical instruments, putti, masks, and comedy actors, such as in "The Rope Dancer and the Dromedary" (*c.* 1689; Mobilier National, Paris).

Both Oudry and Boucher designed for the Beauvais factory. The "Fables of La Fontaine," by Oudry, were among the most popular tapestries of the 18th century. In 1736 Boucher designed Italian genre scenes for the set "Village Festivities" and later in the "Second Chinese Set" did Chinese fantasies. He also designed various pastoral scenes with titillating overtones. The Beauvais factory became noted for tapestry to upholster furniture with and panels for screens. These were usually floral designs and in the 19th century were especially fashionable in finely woven silk (Figure 102). By the end of the century, though technical standards were maintained, artistic deterioration set in.

The Aubusson–Felletin factories

Factories at the neighbouring old tapestry-making communities of Aubusson and Felletin, which had operated for a century and a half as modest private undertakings, were allowed to use the royal Aubusson mark as of 1665. From a small house industry, in which weavers independently produced inexpensive tapestries on their own low-warp looms for a bourgeois clientele, the tapestry makers soon produced hangings, upholstery fabrics, and carpets in Aubusson. The most effective tapestries are the chinoiseries, or genre fantasies set in China, a theme popular in Rococo art. Those designed by Jean Pillement (1728–1808) are especially famous (Figure 103). Coarse and rather dull, the *verdures,* or "garden tapestries," which were the first Beauvais tapestries, were made in quantities. Aubusson architectural panels either imitate those of the Gobelins and Beauvais factories, often with more complex elements and the addition of animals, or depict a damasked wall hung with a painting or cluster of decorative objects and garlands. The factory was especially successful in its production of carpets with conventional geometric ornamental motifs or floral designs.

Figure 103: *18th-century French tapestry.* "The Pagoda," chinoiserie tapestry woven at Aubusson and designed by Jean Pillement, 18th century. In the Mobilier National,Paris. 2.85 × 5.84 m.

The dominant influence on the Brussels industry of the 17th century was the Antwerp painter Peter Paul Rubens, whose most famous set was the "Triumph of the Eucharist" (1627–28). Imitations and adaptations of his style were legion. Heavy and elaborate columns were often substituted for side borders. On a more modest scale are the tapestry versions of genre paintings by David Teniers the Younger (1610–90), in which the border frequently simulated the actual picture frame.

The first major tapestry factory to be established in Germany was founded in 1604 in Munich by Duke Maximilian of Bavaria. The designers and weavers were all Flemish. Although the factory closed after only 11 years of operation, the quality of its workmanship was outstanding. Following the loss of religious freedom in France when the Edict of Nantes was revoked in 1685, many French weavers, especially from the Aubusson factory, sought refuge from persecution in Germany as had the persecuted Flemish weavers of the 16th century. The workshop established in 1686 in Berlin by the great elector Frederick William of Brandenburg (1620–88) employed many of these displaced Aubusson weavers. It produced tapestries mainly for the palaces built by the Great Elector's son, King Frederick I of Prussia (1657–1713), after whose death the factory closed.

French designers and weavers continued to produce a large number of tapestries in the 18th century. Tapestry production was centred principally in Munich, Berlin, Würzburg, Dresden, Schwabach, and Erlangen.

Scandinavian folk tapestry

In Scandinavia tapestries for the Danish and Swedish royalty were woven in Copenhagen and Stockholm. The weavers and designers were usually French and Flemish. Norway and Sweden continued to produce folk tapestries. Of the nearly 1,300 registered Norwegian tapestries, approximately 1,250 originated in small rural communities. These tapestries were usually coarse in texture, stylized and schematic in design, and boldly coloured (Figure 104).

James I established in 1619 by royal charter a factory of tapestry weaving at Mortlake near London. It was staffed by 50 Flemings. Philip de Maecht, a member of the famous late 16th- and 17th-century family of Dutch tapestry weavers, was brought from the de La Planche-Comans factory in Paris, where he had been the master weaver, to hold the same position at Mortlake. The royal factory flourished under the patronage of the Stuart monarchs James I and Charles I. Many of the early tapestries produced at Mortlake were modeled after hangings woven in Brussels. Rubens supplied cartoons and in 1623 suggested to Charles I the purchase of seven of the Raphael cartoons for the "Acts of the Apostles." A new set was woven from these cartoons at Mortlake and is preserved at the Mobilier National in Paris. The redesigned borders have been attributed to the renowned Flemish painter to the English court, Sir Anthony Van Dyck (1599–1641). Although the factory weathered the Puritan austerity of the Commonwealth period, it deteriorated under Charles II and closed in 1703.

From the late 17th century Francis Poyntz (died 1685) and his brothers had a studio in Soho, where a number of weavers originally employed in the royal factory produced a distinct style of tapestry based on Chinese and Indian lacquerwork.

Italian tapestry factories

Cardinal Francesco Barberini, the nephew of Pope Urban VIII, in 1633 established a tapestry factory in Rome. Even though it enjoyed papal patronage, it lasted only until 1679. Clement XI tried to establish another Roman tapestry works in 1710, which also failed. During the 18th century other small factories briefly existed in Turin and Naples. They were staffed mainly with weavers left unemployed by the closing of the Medici factory (Arrazeria Medicea) in Florence.

During the 15th and 16th centuries Franco-Flemish tapestries were imported in great quantities, and Flemish weavers were invited to Spain in order to repair and care for them. For a short time in the 17th century a factory, established by Philip IV (1605–65), operated at Pastrana near Madrid. It was not until Philip V (1683–1746) established the Real Fábrica de Tapices y Alfombras de Santa Barbara (Royal Factory of Tapestries and Rugs of St. Barbara) in 1720 at Madrid, however, that important tapestry was produced in Spain. Initially, the weavers and director were Flemings. The first tapestries made at Santa Barbara were woven from the cartoons of such Flemish Baroque painters as David Teniers the Younger (1610–90) and Philips Wouwerman (1619–68) or based on famous paintings by such Italian artists as Raphael and Guido Reni (1575–1642). When the early Neoclassical painter Anton Raphael Mengs (1728–79) became director, the factory entered its most brilliant period of production. The Spanish painter Francisco Bayeu (1734–95) and his painter son-in-law Francisco Goya (1746–1828) were commissioned to make cartoons. From 1777 to 1790 Goya made 43 cartoons for the "Los Tapices" ("The Tapestries") series depicting Spanish daily life. The painted models for this are among the finest works of Goya's Rococo style.

The French destroyed the factory in 1808, but after the Napoleonic occupation, production was resumed until 1835. The tapestries produced during this period were largely copies of works woven in the 18th century.

A tapestry factory staffed by weavers from the Gobelins was established at St. Petersburg in 1716 by Tsar Peter the Great (1672–1725). Although tapestries were produced until 1859, production was often plagued with difficulties. The most striking designs were a set of grotesques (1733–38) and a series of portraits, of which those of Catherine the Great (1729–96) are the most noteworthy.

19TH AND 20TH CENTURIES

The influence of the Industrial Revolution

Most 19th-century tapestries reproduced paintings or previously woven designs. The influence of the Industrial Revolution was inescapable, of course, not only in tools, materials, and dyes but in the new middle-class market and its demands. Machine-made tapestry, although an achievement in mechanical weaving, became a threat to the survival of the original handicraft.

The necessity for the revitalization and purification of the tapestry art was first recognized by the artists associated with the Arts and Crafts Movement in late 19th-century England. Decrying the loss of individual creativity, they revived the ideals of medieval craftsmanship in an attempt to counter the effects of industrialization on the decorative or applied arts. The leader and most im-

portant figure of the movement was the artist William Morris (1834–96), who established a tapestry factory at Merton Abbey in Surrey near London. For about 15 years he and his associates had been designing not only for looms but also for pictorial wall decorations and stained-glass windows. They were well prepared professionally, therefore, to design tapestries. Morris and the painter-illustrator Walter Crane (1845–1915) contributed cartoon sketches, but most Merton tapestries were designed by the Pre-Raphaelite painter Sir Edward Burne-Jones (1833–98; Figure 105, left). More venturesome than any of the Merton Abbey products were the tapestry designs made in the 1880s by the artist and architect Arthur Heygate Mackmurdo (1851–1942), who in 1882 founded the Century Guild, the first of many groups of artists-craftsmen-designers to follow the teachings of William Morris. This tradition, influenced by the tapestry revival in mid-20th-century France, has continued in Scotland. The most ambitious 20th-century tapestry designed by a British artist, Graham Sutherland's (1903–80) enormous "Christ of the Apocalypse" (1962) for Coventry Cathedral, was, however, woven on looms in Felletin, France. This is the largest tapestry ever to have been made there (78 feet 1 inch by 38 feet 1 inch; 23.8 by 11.6 metres).

Folk traditions in modern European tapestry

In Europe during the late 19th century there was a resurgence of tapestry based on folk traditions. This trend was already apparent in Norway shortly after 1890, when special efforts were made to base a modern tapestry art on native medieval weavings. The leaders were Gerhard Munthe (1849–1929), a well-known painter, and Frida Hansen (1855–1931), a weaver who studied the peasant craftsmanship of Norway and evolved an individual, light, and open weave. Somewhat later developments in Scandinavia occurred in Sweden and Finland. Märta Måås-Fjetterström (1873–1941) became the best known Swedish tapestry artist, and her atelier continued to produce excellent works. In Finland a freer, more colourful art, more delicately scaled, has been practiced by many; among the best known are Martta Taipale, Laila Karttunen, and, for damask tapestry, Dora Jung. In Norway and to a lesser degree in Denmark, similar work has been done. The church in the Scandinavian countries has been unusually receptive to this art. Traditional folk weaving was also behind the revival of tapestry making in several other countries after World War I, including Czechoslovakia and Hungary. Poland produced especially original designs executed in a remarkably free technique. Following the tradition of heavy-grained native weaving, mid-20th-century Polish designer-weavers such as Magdalena Abakanowicz (Figure 106, top right) and Wojciech Sadley used unconventional materials such as jute, sisal, horsehair, and raffia in abstract tapestries that emphasize the nature of the material, tactile stimulation, plasticity, or surface relief.

Germany, emulating Scandinavia, also began a revival of tapestry weaving around the turn of the century. In the state of Schleswig-Holstein a small tapestry industry was set up from 1896 to 1903 at Scherrebek (Figure 105, right), followed by similar enterprises at nearby Kiel and Meldorf. The most significant development, however, occurred at the design school of the Bauhaus, where tapestry was created during the 1920s and early 1930s. Abstract in composition, the Bauhaus designs were deeply rooted in the theory that the technology of the craft should be revealed in the work and in expressing the nature of the materials used, especially by the exploitation of heavy fibres as strong textural elements. Anni Albers, wife of the painter and Bauhaus instructor Josef Albers, became the chief practitioner of this kind of tapestry (Figure 106, top left). Like most modern tapestry weavers, she also designed for the textile industry. After World War II, tapestry works were established in Munich and Nürnberg, and individual weavers worked throughout Germany and in Vienna. Among the Germans, unlike the French, stained glass rather than tapestry generated greater enthusiasm as a revived craft in the post-World War II period. A few indi-

vidual designers worked on their own looms in the United States and Canada, where most large-scale tapestries continued to be imported from Europe. The Latin-American revival of indigenous folkcrafts aroused interest in tapestry making in Mexico and Panama. South American centres of tapestry art developed in Brazil, Chile, and Colombia.

Modern tapestry design was hindered during the greater part of the 19th century in France by the academic administration of the state factories, although progressive artists began to be affected by the English Arts and Crafts Movement in the late 1880s. The painters Paul Gauguin (1848–1903) and Émile Bernard (1868–1941) were among those who took an interest in tapestry weaving, though they did not actually do tapestry cartoons as did Aristide Maillol (1861–1944). It was not until after World War I that France initiated and led the 20th-century revitalization of tapestry as an art. Many of the great modern artists of the school of Paris—Pablo Picasso (1881–1973), Georges Braque (1882–1962), Henri Matisse (1869–1954), Fernand Léger (1881–1955), Georges Rouault (1871–1958), and Joan Miró (1893–1983), among others—permitted their works to be reproduced in 1932. These reproductions were done with extraordinary fidelity under the supervision of Marie Cuttoli, a Paris connoisseur and promoter of exceptional taste. The Aubusson factory, chosen for this important weaving, became once again a great centre for tapestry. The direct translation of painting into tapestry, however, left little scope for the weaver, and it is the trend begun simultaneously by Jean Lurçat (1892–1966) that may be said to have truly inaugurated the 20th-century tapestry renaissance. Although he began experimenting in 1916, Lurçat's art did not become definitive until the 1930s, when under the influence of Gothic tapestry, particularly the 14th-century "Angers Apocalypse," and in collaboration with François Tabard, master weaver at Aubusson, he formulated the principles that were to make tapestry once again a joint creation between artist and weaver—an art in its own right. No longer merely an imitation painting, tapestry once again exploited the coarser texture and the bolder but more limited range of colours that characterized medieval hangings.

French revitalization of the tapestry art

In 1947 Lurçat founded the important Association des Peintures-Cartonniers de Tapisserie (Association of Cartoon Painters of Tapestry). Also active in this organization were the important French tapestry designers Marc Saint-Saëns and Jean Picart Le Doux, who were Lurçat's foremost disciples. Lurçat was held in great esteem by Dom Robert, a Benedictine monk whose tapestries of poetic fantasy were largely inspired by Persian and medieval European manuscript illumination. Other major French designers of representational compositions were the artists Marcel Gromaire (1892–1971) and Henri Matisse and the architect Le Corbusier (1887–1965).

In the 1950s tapestry designs became increasingly abstract. Among the most notable pieces were those designed by the sculptor and printmaker Henri-Georges Adam (1904–67). Using only black and white, his tapestries are monumental tonal abstractions that reflect his work as an engraver (Figure 106, bottom). The sculptor Jean Arp (1887–1966) and the painter Victor Vasarely are other abstract designers of postwar tapestries.

After World War II the Belgians, influenced by the weaving activity in France during the 1930s, revived their tapestry industry. In 1945 the Forces Murales movement was organized in Tournai by cartoon painters including Louis Deltour, Edmond Dubrunfaut, and Roger Somville, who became the leading designers of Belgian tapestries. This was followed in 1947 by the organization in Tournai of a collective tapestry workshop, the Centre de Rénovation de la Tapisserie, active until 1951. Small workshops continued to flourish in Belgium, especially in the cities of Tournai, Brussels, and Malines.

The renewed international interest in tapestry is clearly related to the austerity of modern architecture. Suitable settings for large-scale wall hangings are provided by the often vast expanses of bare wall surface in contemporary buildings. Le Corbusier not only used tapestries to decorate his architectural interiors but designed them. He frequently referred to tapestries as nomadic murals, recognizing their importance as movable and interchangeable decoration.

In 1962 the first international exhibition of tapestry was held at Lausanne in Switzerland, which after 1965 became an important biennial event. This exhibition clearly demonstrates the tremendous worldwide interest in the medium generated in the middle 20th century as well as indicating the immense variety of tapestry designs, materials, and techniques. (M.J.)

FLORAL DECORATION

Since the earliest days of civilization, man has used floral decorations, composed of living or dried cut-plant materials or artificial facsimiles, to embellish his environment and his person. They have played an important part in folk festivals, religious ceremonials, public celebrations of all kinds, and, of course, courtships. Sophisticated cultures have generally expressed a love for decorating with flowers by carefully arranging them in especially chosen containers, while less sophisticated societies have used them more informally: strewn, made into garlands and wreaths, or casually placed in waterholding vessels without thought of arrangement.

This section covers the elements and principles, the materials, the techniques and forms, and, finally, the historical and stylistic developments of floral design.

Elements and principles of design

The term flower arrangement presupposes the word design. When flowers are placed in containers without thought of design, they remain a bunch of flowers, beautiful in themselves but not making up an arrangement. Line, form, colour, and texture are the basic design elements that are selected, then composed into a harmonious unit based on the principles of design—balance, contrast, rhythm, scale, proportion, harmony, and dominance. Line is provided by branches or slender, steeple-like flowers such as snapdragon, delphinium, and stock. Form and colour are as varied as the plant world itself. Moreover, forms not natural to the plant world can be created for contemporary abstract compositions by bending and manipulating branches, vines, or reeds to enclose space and create new shapes. Texture describes surface quality and can be coarse, as in many-petaled surfaces such as chrysanthemums, or smooth, as in anthuriums, calla lilies, and gladioli. There are many variations between these extremes. Leaves and woody stems also have varied textural qualities.

A flower arrangement includes not only the flowers themselves but the container that holds them and the base on which the container may rest. If an accessory, such as a figurine, is included, that too becomes a part of the total design. The whole composition should relate in textural quality to its frame of reference, which might be a wood or glass table top or a linen cloth, and should be in close harmony with the style of the room for which it was planned, be it Louis XV or Danish modern.

Line and mass

As the components of a design are selected and combined, a silhouette, or arrangement outline, is created. This outline is generally considered most interesting when the spaces in the composition vary in size and shape. Third dimension, or sculptural quality, is accomplished by allowing some of the plant materials in a grouping to extend forward and others to recede. Flower heads turned sideways, or toward the back, for example, break up contour uniformity and draw the eye into and around the composition. When a formal, static quality is sought, the contour is restricted or evenly shaped, often into such graduated forms as a pyramid or mound.

Balance is psychologically important, for an arrangement

that appears to be leaning, top-heavy, or lopsided creates tension in the viewer. (Occasionally, however, as in some modern arrangements, this is the very effect desired.) Colour as well as the actual size of the plant material influences design stability. Dark colour values look heavier than light values; a deep red rose, for example, appears heavier in an arrangement than a pale pink carnation, even though they are the same size. An arrangement in which dark colours are massed at the top and light colours at the bottom can therefore appear top-heavy. Similar flowers placed in identical positions on either side of an imaginary vertical axis create symmetrical balance. If there is an unequal distribution of varying flowers and leaves on either side of the axis but their apparent visual weight is counterbalanced, asymmetrical balance is achieved. This compositional device is more subtle and often more pleasing aesthetically than symmetrical balance, for its effect is less apparently contrived and more varied. Contrasts of light and dark, rough and smooth, large and small, also give variety to the composition. An arrangement generally has a dominant area or centre of visual interest to which the eye returns after examining all aspects of the arrangement. An area of strong colour intensity or very light values, or a rather solid grouping of plant material along the imaginary axis and just above the container's rim, are devices commonly used as compositional centres.

Rhythm, scale, proportion, and harmony

The rhythm of a dynamic, flowing line can be achieved by the graduated repetition of a particular shape, or by the combination of related colour values. Scale indicates relationships: the sizes of plant materials must be suitably related to the size of the container and to each other. Proportion has to do with the organization of amounts and areas; the traditional Japanese rule that an arrangement should be at least one and a half times the height of the container is a generally accepted use of this principle. Proportion also relates to the placement of the arrangement in a setting. A composition is either overpowering or dwarfed if placed on too small or too large a surface or in too small or too large a spatial setting. Harmony is a sense of unity and belonging, one thing with another, that comes with the proper selection of all the components of an arrangement—colour, shape, size, and texture of both plant materials and container.

Materials

Many different kinds of plant materials are used in floral decorations, among them flowers, foliage, grasses, grains, branches, berries, seeds, nuts, cones, fruits, and vegetables. The materials may be living, dried, or artificial. Initially, man was restricted to using native wildings, or uncultivated plants, but as civilization developed over a period of thousands of years, man became less dependent on the seasons and on the resources of the particular region in which he lived. As means of transportation improved and trading grew, plants were introduced from foreign countries and many have since been hybridized to improve or vary shape, size, and colour. In the 20th century the floral decorator has an enormously varied medium in which to create because plant materials can be flown from one part of the world to another. Since the 19th century, when extensive greenhouse cultivation first made it possible to purchase fresh flowers at any time of the year, there have been commercial growers of plant materials who supply the world's floral wholesale markets. The Netherlands, for example, is famous for the 10-mile stretch of greenhouses at Aalsmeer near Amsterdam. In the United States, California and Florida, particularly, have vast areas under cultivation for commercial flowers.

Living plant materials

Dried plant materials are generally used for what is traditionally called a winter bouquet. The cultivated flowers that are often dried are those with a naturally dry, stiff surface quality—such as strawflowers (*Helichrysum bracteatum*), globe amaranth (*Gomphrena*), and statice. North temperate zone wildings picked and preserved for dried arrangements include pearly everlasting, heather, and the sea lavender of salt marshes, as well as goldenrod, orange bittersweet berries, cattails, dock, teasel, and sumac. Many kinds of grasses—pampas, sea oats, millet, and sorghum, for example—are also dried, as are seed-bearing capsules such as the flat paper disks of honesty (*Lunaria*), orange Chinese lanterns (*Physalis*), and the wood roses from the Hawaiian morning glory (*Ipomoea tuberosa*). Other dried materials sometimes used in floral decorations are cones and nuts, long used for making wreaths and festoons for such winter festivals as Christmas; straw, used for Christmas decorations in Sweden and Lithuania; and grains, especially wheat and oats, often arranged in bunches for harvest decorations in Europe and America. Because of their fleshy substance, most fruits and vegetables do not dry well; the main exceptions are gourds, pomegranates, and artichokes.

There are various ways of drying plant materials. Certain garden flowers (among them celosia, blue salvia, globe thistle, alliums, and hydrangeas) can be gathered at their peak of bloom and dried by hanging them upside down in a dark, dry place for several weeks. Flowers may also be individually dried using one of several techniques. A 17th-century Italian writer on horticulture, P. Giovanni Battista Ferrari, described a process of gently burying the flower heads in clean, sun-dried sand and allowing them to remain in a sun-heated place for several months. The same method was used in the 19th century. Later, borax was used, and in the 20th century silica gel, because of its ability to absorb moisture. This solution is gently brushed between and over every petal. Since this method of drying does not preserve the stems, the flower heads must be wired before they are arranged.

Leaves and ferns are dried by pressing. The most delicate pressed flowers and foliage have been composed, mounted, and framed as pictures—a practice especially popular with 19th-century Romantics, who preserved floral souvenirs as sentimental personal memorabilia.

Throughout history and in almost every conceivable medium man has created artificial plant materials. The

Figure 107: Shell-flower arrangement, English, early 19th century. Shells, fastened to the surface of a superstructure, have been used to form an intricate artificial bouquet. In the Victoria and Albert Museum, London.

Artificial plant materials

Chinese fashioned peony blossoms and fruits from semiprecious stones and carved jade leaves, which they assembled into small trees. Gold lotus blossoms were highly treasured in eastern Asia. For European royalty in the late 19th century, the Russian-born jeweller Peter Carl Fabergé (1846–1920) designed exquisite single-stemmed flowers of gold, enamel, gems, and semiprecious stones set in small rock-crystal pots. During the 18th and 19th centuries, the Sèvres porcelain factory in France produced porcelain flowers with stems and leaves of ormolu (a metallic alloy resembling gold). At the same time, the Royal Worcester, Crown Staffordshire, and Royal Doulton factories in England became world-famous for their highly realistic porcelain floral arrangements, which are still made. The Victorians developed a home craft of making and arranging flowers and fruits. Wax, cloth, yarn, feathers, shells, and seeds were used to make the flowers and fruits, which were then either framed or placed under glass domes (Figure 107). Perhaps the most curious of these 19th-century decorations were the wreaths and floral displays made by twisting, knotting, and weaving the hair of one's family and friends around wire supports. Beaded flowers for cemetery and funerary bouquets have been popular in France since the 19th century; and paper flowers for festivals and home decoration have become a major folk art medium in Mexico and Japan. Because of their relatively low cost, durability, and easy maintenance (an occasional washing or dusting), plastic flowers and plants are in such great demand that their production has become an important 20th-century industry. Though still primarily used in public places, plastic plant materials are increasingly found in private homes, especially in the United States.

Techniques

Cut plant materials, especially flowers, need special care and treatment before they are placed in vases. Ideally, flowers are picked some hours before they are arranged and never in the heat of the day. Generally, the bottoms of the stems are cut on a slant, placed in deep tepid water, and kept in a cool place, preferably overnight. Different materials have different conditioning needs. Woody stems are split several inches with pruning shears, then soaked in hot water. Stem ends may be crushed with a mallet instead, but clean cuts make it easier to impale branches on a needle holder. Milky stems, such as those of poppies, poinsettias, and large dahlias, are sealed by placing the tips in boiling water or over a flame for a few seconds. Foliage and flowers are protected from steam and flame by inserting the stems through a hole punched in newspaper, which is then drawn up over them. When arranging flowers, all foliage below the water line must be removed in order to prevent bacterial decay and the resulting unpleasant odour. Since the stems of flowers often seal over while being held in a florist shop or market, they must be recut by the purchaser. Packaged formulas do not aid in revival but are meant to be used during the preliminary soaking period. Roses and woody-stemmed flowers such as chrysanthemums can frequently be revived by recutting and placing them in hot water.

Arranging techniques

Many tall containers can easily display flowers without holding mechanics, but if necessary they can be stuffed with upright pieces of privet or fine evergreens, such as juniper, which are sheared flat across the vase opening. The Japanese *kenzan*, or metal pin holder, usually called a needlepoint holder, is the most generally used mechanical aid. It is held in place with floral clay. In silver vases, melted paraffin is used as a fastener, for, unlike clay, it will not tarnish the container and can be removed easily with hot water. Crumpled chicken wire, or wire netting, is frequently stuffed into vases as an aid to support, and a water-absorbing plastic foam, sold in bricklike blocks, has also become very popular.

Containers and bases

The selection of a suitable container is an individual problem in every arrangement. It is considered a part of the overall design of the arrangement and is related to it in scale, colour, and texture. Its colour must enhance, not compete with, the arrangement. For the same reason many floral decorators prefer to use simply shaped, unadorned vases. The texture of the container is also chosen for compatibility with the floral arrangement. Coarse, heavy plant materials are usually arranged in a substantial container of pottery, pewter, copper, or wood. Delicate flowers and foliage are usually displayed in porcelain, glass, or silver. Fruits and vegetables are often arrayed in wooden or pottery bowls and baskets. The size of the container is also important. If it is too small, the plant materials will overpower it and the arrangement will appear top-heavy. If it is too large, it will not only dwarf the arrangement but will frequently destroy the unity of the composition, dividing the viewer's attention between the floral arrangement and the container. Containers are not used for all arrangements of plant materials. Compositions of driftwood, flowers, fruits, and vegetables are often arranged on a flat base of wood or bamboo, a tray, or slab of wood. To keep them fresh, flowers or foliage used in such an arrangement often are placed in solid-walled pin holders that hold water.

A wooden base frequently completes a composition, since it can add visual weight at the bottom, which assists in balance. The Japanese traditionally use wood or lacquer bases and stands with all arrangements, and a porcelain vase in China was not considered complete without a carved teakwood stand. The stand has both aesthetic and practical advantages: it adds height to a display and prevents moisture stains on furniture or textiles.

Forms of floral decoration

Plant materials are customarily arranged in containers, woven into garlands, and worn or carried for personal adornment. Flower bouquets that are carried include the nosegay and corsage. In the mid-19th century, the nosegay, or posy (a small bunch of mixed flowers), was much in fashion. No well-dressed Victorian lady appeared at a social gathering without carrying one, edged with a paper frill or delicate greens and sometimes inserted into a silver filigree holder (Figure 108). Messages of love were often spelled out in the flowers of the nosegay, for the

Nosegays and corsages

Marc Garanger

Figure 108: Elegant 19th-century use of flowers for personal adornment: "Empress Eugénie," oil on canvas by Édouard Dubufe, 1854. In the Musée National de Versailles et des Trianons, Versailles, France

"language of flowers" was carefully studied at the time, and courtships progressed through the sending of such floral symbols.

Worn since the 18th century, the corsage has become especially popular in the 20th century. Instead of a nosegay, an admirer frequently sends a lady an orchid, a gardenia, or a small bunch of wired flowers to be worn at the waist, shoulder, or on the wrist, or attached to a handbag and carried. Only the flower heads are used in a corsage. Wires are inserted through the calyx (the usually green or leafy external portion of a flower) and bent to thrust the flowers forward or to the side; then the ends are bound together with tape or ribbon. Leaves or foliage threaded crosswise with wire are usually added. A ribbon bow often completes the corsage.

Sprays are large, flat bouquets of long-stem plant material. They are either carried or placed on caskets or at tombs as commemorative offerings. If the plant material used is short-stemmed, wire is used to add length. The ends of the stems or wire extensions are frequently thrust into a block of moss or stiff plastic foam to secure the arrangement. A blanket of flowers is often laid over a casket at a funeral or over a racehorse in the winner's circle. Blankets are made by stretching burlap over a frame, covering it with a layer of flat fern, and then adding delicate asparagus fern (*Sprengeri*). The fern surface is then covered with flower heads, which are threaded with wire and fastened on the underside of the blanket.

Garlands and wreaths

Garlands are bands of plant materials that have been woven or in some other way attached together; they are not arranged in a container. A circular garland is called a wreath, or if it is worn around the head, a chaplet. Garlands draped in loops are called festoons or swags. The origin of these forms is unknown, but evidence of their use dates from ancient times and is not restricted to any particular culture.

Garlands have been used for many purposes. Ancient Egyptians placed them on mummies. The Greeks used them to decorate their homes, civic places, and temples. For festive occasions the ancient Romans wore garlands of strung rose petals. When these garlands of roses were suspended from ceilings, the conversation that took place beneath them was sub rosa. On European festival days such as Corpus Christi, cattle are bedecked with neck garlands. On Indian holy days, the Hindus take garlands to the temple to be blessed before wearing them; they also hang garlands on the statues of their deities.

SCALA—Art Resource

Figure 109: Figures wearing wreaths of leaves and flowers, "Heracles and Telephos Before the Personification of Arcadia," Roman wall painting from Herculaneum (*c.* 1st century AD), after a Hellenistic original, early 2nd century BC. In the Museo Archeologico Nazionale, Naples.

In the ancient world it was probably the Romans who most fully developed the ornamental form and use of the festoon. Fine examples are carved in marble on the Ara Pacis or Altar of Peace (13–9 BC) near the Mausoleum of Augustus in Rome. Roman festoons were usually made of fruit, grain, leaves, and flowers. In the late 17th and early 18th centuries it was fashionable, particularly in England, to create artificial festoons over fireplace mantels. Called swags, they were usually carved of wood. Among the most famous are those executed by the English sculptor Grinling Gibbons.

Wreaths have been both worn and displayed. In antiquity the wreath was bestowed upon public officials, athletes, poets, and returning warriors. The ancient Greco-Roman custom of bestowing a laurel crown, or wreath, upon a poet was revived during the Renaissance, especially in Italy. Napoleon chose a laurel wreath of gold for his crown, emulating the emperors of the Roman Empire. At Christmas time since the 19th century, wreaths of evergreens, holly, or pinecones and nuts have been traditionally hung as decorations in northern Europe, the United States, and Canada. In medieval and Tudor England the boar served for Christmas dinner had a wreath of rosemary and bay. During Advent, a period including the four Sundays before Christmas, a wreath with four candles (each symbolizing one of the Advent Sundays) is traditionally hung in Christian homes and churches.

Plant materials have been used for personal adornment in forms other than corsages, nosegays, garlands, and wreaths. Ancient Egyptian wall paintings show women with lotus blossoms in their hair, and today the hibiscus adorns the hair of women of the South Seas. Necklaces of flowers are commonly worn in South and Southeast Asia. In Hawaii, Vanda orchids or velvety frangipani blossoms are strung into long necklaces called leis, the customary gifts of both welcome and farewell.

Many types of dress accessories are decorated with flowers. Staffs ornamented with plant material are seen in ancient art and mentioned in ancient literature. Egyptian servants or standard bearers were often depicted holding staffs of papyrus and lotus blossoms. An attribute of Dionysus and his satyrs was the thyrsus, a staff topped by a pinecone and sometimes further decorated with vine or ivy leaves and grapes. Well-known flowering staffs or rods include those of Aaron, the brother of Moses, and St. Joseph, the earthly father of Jesus.

Flower pictures and floats

Pictorial effects have been achieved by using cut flower heads or petals to create masses of colour that are then worked into patterns. The traditional carpet of flowers laid down on the Via Livia in Genzano, Italy, for the feast of Corpus Christi is incredibly intricate and colourful. Figures of angels, madonnas, and saints, geometric designs, and coats of arms are worked out with flower petals to form a carpet over which the religious procession passes. Mexicans frequently carpet their churches with mosaics of wild flowers, and in The Netherlands during tulip time flower pictures are made for competition. About 12 feet square, made for the most part of tulip and hyacinth blossoms, they are designed on inclined backgrounds for better visibility. Some of these pictures are three-dimensional.

For centuries flower-covered floats have been used in parades. The Italian painter and architect Giorgio Vasari (1511–74) described 21 garland-decorated floats he designed for a pageant in Florence. The most famous of modern floral parades is the Tournament of Roses parade held on New Year's Day at Pasadena, California. Floats up to 50 feet (15 metres) in length are constructed over the chassis of motor vehicles. Rough framework is covered with chicken wire shaped and sprayed with a polyvinyl coating. Flower heads are attached with either glue or wire.

Historical and stylistic developments

WESTERN

Ancient world. There is evidence through painting and sculpture that during the Old Kingdom (*c.* 2686–*c.* 2160

BC) the Egyptians placed flowers in vases. In the tomb of Perneb bas-relief carvings show lotus blossoms and buds alternately arranged in flared bowls that were set upon banquet tables or carried in processions. Paintings of functional vases with spouts designed to support the heavy-headed lotus flower are found in the tombs of Beni Hasan (*c.* 2500 BC). Formal bouquets of lotus and berries offered to the dead are represented in the paintings from the tomb of Apuy at Thebes (Figure 110, top). Garlands and wreaths, floral headdresses, and collars were woven. Because of the formalized rules of Egyptian art, the lotus (*Nymphaea*), sacred to the goddess Isis, and papyrus, both of which were easily conventionalized, were the plant materials depicted almost exclusively for 2,000 years. During the Ptolemaic era (305–30 BC) perfume recipes, flower garlands found on mummies, and Greek and Roman writings reveal a more varied native plant life and show that foreign plants had been introduced, most notably the rose.

The ancient Greeks' love of flowers was expressed mainly in the making and wearing of wreaths and garlands (Figure 109). Vase paintings, temple friezes, and architectural ornamentation all illustrate their widespread use. They were also frequently mentioned in Greek literature. The techniques of making garlands and wreaths, the most appropriate plant materials, and the proper time and way to wear or display them, were the subjects of several treatises. Fruits and vegetables mounded in baskets or spilling in profusion out of a cornucopia were types of arrangements used for religious offerings.

The earliest depiction of mixed cut flowers, artfully arranged in a container, is a mosaic dating from the early 2nd century AD of a basket of flowers from the emperor Hadrian's villa at Tivoli near Rome (Figure 110, bottom). Garlands and wreaths continued to be popular among the Romans, as did displays of fruits and vegetables in cornucopias and baskets.

Middle Ages. Little evidence remains of floral decoration in early medieval Europe. In the mosaics of Ravenna, the Byzantines depicted highly contrived formal compositions. Symmetrical, with an emphasis on height, these arrangements were usually spires of foliage with regularly placed clusters of flowers or fruit.

Medieval plant symbolism

Illuminated manuscripts of the Gothic period (from the 13th century to the 15th) occasionally include simple floral bouquets holding symbolic flowers. This was a time of intense religious fervour, and plant symbolism assumed great importance. There was both a liturgical and a secular language of flowers. In the church, for example, the rose symbolized the Virgin; in the chivalric courts, passionate love. Usually plant materials were casually placed in utilitarian containers such as earthenware jugs, bottles, glass tumblers, and in majolica, or glazed and enamelled pottery, drug jars called albarelli. The still life in the foreground of the open centre panel of the "Portinari Altarpiece" by the Flemish painter Hugo van der Goes (Figure 111) is an illustration of this type of arrangement. Metal ewers often held Madonna lilies (*Lilium candidum*), as in the 15th-century painting "The Annunciation" by Rogier van der Weyden (Metropolitan Museum of Art, New York).

15th and 16th centuries. Floral decorations became more studied and elaborate during the Renaissance period of the 15th and 16th centuries. The revival of interest in antiquity influenced the widespread use of garlands and wreaths in Renaissance Europe, especially in Italy. They were popular for pageants and feasts as well as for decorating houses and churches, and were commonly depicted in the art of the time. Among the most notable examples are the terra-cotta wreaths that framed the decorative ceramic plaques and reliefs made by the della Robbia family in the

late 15th century, and the garlands of flowers, fruits, and vegetables in the paintings of such northern Italian masters as Andrea Mantegna and Carlo Crivelli (Figure 112). Cut-plant materials were generally arranged in either high sparse bouquets or tight low bunches. There were also pyramidal compositions in pedestal vases, such as those in the background of the painting "Virgin and Child and St. John" (Borghese Gallery, Rome) by the Florentine artist Sandro Botticelli. Arrangements of fruits and vegetables on salvers or in baskets also were popular.

17th century. The arrangement of plant materials truly became an art and an important decorative device in the 17th century. During this period of worldwide exploration, colonization, and commerce, new plants were introduced into Europe, where an avid interest in horticulture developed. Still-life paintings of the late 16th, 17th, and early 18th centuries reveal what a great variety of plants there was in the gardens of Europe. Beginning with Jan Brueghel (called "Velvet Brueghel"; 1568–1625), a tradition of flower painting developed in Flanders and Holland, which culminated with the works of Jan van Huysum (1682–1749). The canvases of the many hundreds of still-life painters of the period are valuable source material for the student of the history of floral decorations and gardens. They must, however, be considered as idealized compositions and not as literal translations onto canvas of actual bouquets. Early 17th-century pictures, particularly those of Jan Brueghel, who painted one-of-a-kind arrangements, seemed most interested in displaying the content of the garden itself. Depictions of later 17th-century bouquets show profuse arrangements that reflect the sensuality and exuberance of the Baroque style. Curvilinear elements such as sinuous S curves are other Baroque devices of design used to createGrandiloquent, dramatic compositions. The massed bouquets of the Baroque period are studies in dominance, contrast, rhythm, and sculptural effect. The eye is drawn around and into the bouquets by the turning of flower heads, the reversing of leaves, and the curving of graceful flower stems.

National styles of arrangement

The French style of the Louis XIV period (1643–1715) is best exemplified in the flower engravings of Jean-Baptiste Monnoyer. The plates for his famous portfolio *Le Livre de toutes sortes de fleurs d'après nature (Book of All Kinds of Flowers from Nature)* accurately portray flowers from a horticultural standpoint and at the same time show prototypes of display. These floral arrangements are freer and more airy than those of the Low Countries and yet suggest Baroque opulence. *Flora ouero cultura di fiori* ("Flora: The Cultivation of Flowers"), a renowned garden book published in Rome in 1633 by the horticulturist P. Giovanni Battista Ferrari, illustrates the styles of floral displays preferred by the Italians and also describes arranging techniques and devices. Among the ingenious devices illustrated is a vase with holes in its removable top that made it easy to arrange flowers and change water.

18th century. The floral arrangements of the early 18th century were dominated by French and English taste. In France, cultural and social life centred in the intimate rooms of Parisian town houses rather than in the vast rooms and halls of Louis XIV's Versailles palace. Bouquets, therefore, were comparatively small, to be in scale with their setting. The more delicate colouring and lighter visual weight of these arrangements can be attributed in part to feminine taste, which decidedly influenced the Rococo style (Figure 113). Personal and charming, the Rococo bouquet and its variations remained popular into the 20th century. English bouquets of the corresponding Georgian period were often more profuse than the Rococo. Many books written to catalog the wide variety of plant materials available in 18th-century England gave incidental information on how to care for and display them. One of the best known of these works is the two-volume *Gardeners Dictionary* by the horticulturist Philip Miller. In it he mentions dried bouquets and chimney flowers. It was customary in English homes to arrange flowers and branches in the hearth during the summer months when the fireplace was not in use. These arrangements were referred to as "bough pots." The best known English illustrations of Georgian flower arrangements are those designed by the Flemish artist Peter Casteels for a nursery catalog called *The Twelve Months of Flowers* (1730). Since the flowers in each bouquet are numbered and keyed to a list at the bottom of the plate, and are one-of-a-kind collections, they are not truly representative of live arrangements. Jacob van Huysum's monthly paintings display flowers more naturally. Both series are invaluable as source material for garden flowers.

The Neoclassical period of the late 18th and early 19th centuries brought about a revival of wreaths and garlands in the style of Greco-Roman antiquity. Floral bouquets were arranged in vases of classical severity.

19th century. The interest of the 19th-century Romantics in nature made floral arrangements an important part of a decorative scheme. With the advent of the clipper ship more exotic plant materials were introduced into Europe and the United States. From China came new varieties of chrysanthemums, bleeding heart, rhododendrons, and azaleas; from South Africa, the gladiolus, freesia, and pelargoniums; and from Mexico, the dahlia, gloxinia, and fuchsia. Many old garden favourites were greatly improved as a result of widespread scientific interest in horticulture and botany. The Industrial Revolution made it possible to manufacture a great variety of economically priced ceramic and glass containers. Artificial flowers were extremely popular and were made in many different materials in both home and factory.

Victorian arrangements

The books and magazines of the Victorian age agreed that the art of arranging flowers was an accomplishment all young ladies should acquire. Except for the single flower in the small bud vase, the most popular style of Victorian arrangement was a tightly compact mass of flowers,

Figure 113: (Left) An exuberant and dramatic Baroque flower arrangement, "Flowers in a Vase," oil on panel by Jan van Huysum, 1726. In the Wallace Collection, London. (Right) An intimate and delicate bouquet of the 18th century, "A Vase of Flowers," oil on canvas by J.-B.-S. Chardin (1699–1779). In the National Gallery of Scotland, Edinburgh.

greens, grasses, and ferns. The two-level epergne, with a flared top for flowers and lower tier for fruit, frequently was used for the centre of the dining table. Since the flowers selected were usually of a brilliant hue, strong colour contrast was a characteristic of Victorian arrangements. These gay floral groupings, however, were usually softened by ferns and other kinds of foliage.

20th century. The book *Flower Decoration in the House* (1907) greatly influenced the development of 20th-century floral decoration as an art. The author was Gertrude Jekyll, already notable in the gardening world. For a long time, floral decoration in big houses had been the charge of the head gardeners or the local florists; in smaller houses, the charge of the mistress of the house. In any case, arrangement was done with varying degrees of skill and little guidance. With Gertrude Jekyll's book, the idea that flower decorations actually could be planned and designed in such a way as to heighten the quality of a room came to be widely accepted. Interior decorators added their specialized knowledge to the practical expression of this view.

The rise of the women's Garden Club movement in the 1930s and the growth of flower shows led to establishing definite rules for arrangement, especially in the United States. The classic Japanese rules of design (see below) were adopted, and others were formulated. Three main types of arrangement were recognized—the mass, the line, and the combination line-mass. Emphasis was placed on design shapes such as the crescent, or Hogarth curve, and colour studies in related or contrasting harmonies. In exhibitions thematic compositions were popular, and often arrangements interpreted abstract ideas, emotions, places, and natural phenomena. Naturalistic compositions with just a few flowers made use of stones, moss, and branches or driftwood with striking line interest (Figure 114). In the mid-20th century flower arranging tended to follow contemporary art trends. A Japanese revolt against traditional aesthetic canons also had great influence on Western development of free-style arrangements that reject naturalism and are often unconventional in their placement and use of treated material. Traditional principles of visual design are often rejected in such modern arrangements.

Assemblages and abstract arrangements

Assemblages of such diverse elements as scrap metal, rope, and plastic are composed with a minimum of plant material. Transition and rhythm yield to heightened contrast. Space is important, and new forms are created by bending plant material to create new shapes. Psychological tension is created by upsetting balance and symmetry.

EASTERN

China and Korea. The ancient Chinese could enjoy and feel themselves at one with the growth, maturity, and decline of a few flowers or a branch. The floral expressions of the Chinese have traditionally been based on the Confucian art of contemplation, the Buddhist principle of preservation, and Taoist symbolism (Figure 115). For the Confucian, a floral arrangement was philosophically contemplated both as a symbol of organic existence and for its aesthetic aspects. Buddhists used flowers sparingly because of their religious doctrine prohibiting the taking of life. At least since the T'ang dynasty (AD 618–907), flowers have been placed on temple altars in a *ku,* an ancient bronze

ceremonial wine beaker dating from the Shang dynasty (18th to 12th century BC) whose shape was translated into porcelain in later dynasties. Hua Hsien, the flower goddesses of the Taoists, have traditionally been represented carrying flower-filled baskets. In Taoist symbolism, the four seasons were denoted by the white plum blossom of winter, the peony of spring, the lotus of summer, and the chrysanthemum of autumn. Each month also had its own flower. Longevity in plant arrangements was symbolized by pine, bamboo, and the long-lasting *ling chih* fungus. New Year floral displays featured the paper-white narcissus, and the tree peony (*Paeonia moutan*), designated the "king of flowers," was used to symbolize good fortune.

Usually the floral arrangements of the Chinese, like those of the Koreans, appear less obviously contrived than those of the Japanese. A composition frequently will be made of two or more arrangements in containers of different heights and shapes, often grouped with rocks or decorative objects. Chinese bouquets in baskets have a quality reminiscent of Western floral arrangements.

Japan. The arrangement of flowers in Japan is an elaborate and unique art, with highly developed conventions and complex symbolism. The art developed from the custom of offering flowers to the Buddha and was introduced into Japan early in the 7th century by Ono No Imoko, Japanese ambassador to China, who founded the first and oldest school of floral art, the Ikenobō. All the later masters of the Ikenobō school are his descendants. Most important among the earliest styles was the *mitsu-gusoku,* an arrangement of three or five articles often consisting of an incense burner, a candlestick in the form of a stork, and a vase of flowers. These were usually displayed before pictures of the Buddha or of founders of Buddhist sects.

Early Japanese styles

Early styles were known as *tatebana,* standing flowers; from these developed a more massive and elaborate style, *rikka* (which also means standing flowers), introduced by the Ikenobō master Senkei around 1460 (Figure 116). The early *rikka* style symbolized the mythical Mt. Meru of Buddhist cosmology. *Rikka* represented seven elements: peak, waterfall, hill, foot of the mountain, and the town, and the division of the whole into *in* (shade) and *yō* (sun). (In Chinese the characters for *in* and *yō* are read *yin* and *yang,* the passive or female and the active or male principles.) Formal *rikka* is arranged out of nine main branches and some accessory ones. Three branches are placed so that their tips form a triangle with unequal sides. From this pattern all later styles of Japanese floral art developed.

In the early 18th century a three-branch, asymmetrical style, *shōka,* evolved from the *rikka* and was cultivated by the Ikenobō school. *Shōka* is written with Japanese characters meaning living flowers. These characters can also be read *seika* and *ikebana; seika* is the preferred reading by some schools, while *ikebana* today is the general term applied to any style of Japanese floral art. Up to the advent of *shōka* all styles of arrangements other than *rikka* had been known as *nageire,* meaning to throw, or fling into. This term was confined to arrangements in tall vases, and *heika,* vase flowers, is preferred to *nageire* by some schools. *Shōka* utilized three main branches, and emulated the natural growth of plant life. This illusion of growth was achieved by using buds, foliage, and blossoms; by superimposing stems as they emerged from the container; by turning up the tip ends of branches unless of a naturally drooping kind; and by placing tree branches above flowers and mountain material above that of the lowland. All combinations were seasonally correct. Uneven numbers of materials were always used, and rules of proportion dictated that plant material be at least one and one half times the height of the container. By the late 18th and early 19th centuries the *shōka* style had supplanted the *rikka* in popularity and many new schools flourished, including Enshūryū, Koryū, Kōdōryu, and Mishōryū. All these new schools utilized the three-branch form but adopted different nomenclatures for them.

By courtesy of the Tokyo National Museum

Figure 116: Traditional *rikka* flower arrangement of nine different plant materials. In the Tokyo National Museum.

Western flowers were introduced into Japan following the Meiji Restoration (1868). The flower master Ohārā Unshin, who established the Ohara school (early 20th century), devised for them a new container, based on the low bowls used for dwarfed plants. This new style, known as *moribana* (heaped-up flowers), permitted greater freedom in the choice and placement of materials. A variation was the creation of small realistic landscapes called *shakei,* sometimes referred to as memory sketches. In these, exposed water surface was a part of the design. In 1930 a group of art critics and flower masters proclaimed a new style of floral art called *zen'ei ikebana* (avant-garde flowers), free of all ties with the past. Foremost in this group was the Ikenobō master Teshigahara Sōfū (1900–79), who had founded the Sōgetsu school in 1927. The

new style emphasized free expression. It utilized all forms of plant life, living and dead, and elements that had been previously avoided, such as bits of iron, brass, vinyl, stone, scrap metal, plastic, and feathers. Vines and branches were bleached and painted and even used upside down. Stems were crossed, even numbers of materials were used, and containers were often crude and exotic in shape.

Until 1868 Japanese flower arrangement was generally a man's avocation, engaged in primarily by Buddhist priests, warriors, and the nobility. Following the Meiji restoration and particularly after the beginning of the 20th century, it was taken up by large numbers of women. Men, however, still head most of the principal schools.

The total number of schools that teach floral decoration throughout Japan in the 20th century is believed to number from 2,000 to 3,000, varying in size from several thousand to millions of adherents. Each school has its own rules of arrangement, though styles may differ only slightly from one another. All arrangements are asymmetrical and achieve a three-dimensional effect. The traditional styles are still taught, many with modern variations, but the bolder, less restrained, and unconventional free-style forms of arrangement now seem to be the most popular. The material used in Japanese floral arrangements is held in position by various artifices, the most popular of which are the *kubari*, forked twig, and the *kenzan*, needlepoint holder.

Japanese flower arranging has influenced that of the West considerably, particularly in the mid-20th century. Many popularizations of the art have flourished in the United States.

OTHER CULTURES

Outside the West and the Far East, the arranging of plant materials was more a casual part of everyday life than a formally recognized medium of artistic expression. The elaborate stylistic traditions evolved and formulated in the West and Far East through centuries of sophisticated creative activity are rarely found, therefore, in other cultures. In the Islāmic world, for example, simple, modestly scaled arrangements predominated: sparse, symmetrically arranged bouquets; casually grouped bunches of flowers; or blossoms floating on liquid surfaces. The garlands made in India for adorning home, temple, statuary, and man himself were simpler than the bouquet or arranged floral materials found in the more aesthetically complex traditions of the West and Far East. Also in contrast to these artistically self-conscious arrangements are the stiff, mounded groupings of plant materials made for festivals in Southeast Asia. (Ju.S.B.)

POTTERY

Pottery in its widest sense includes all objects made from clay and hardened by fire: earthenware, stoneware, and porcelain. This article deals with pottery as art and craft, covering the kinds of pottery, the processes and techniques of forming and decorating it, and, finally, the history of pottery. Since the subject is so vast, the article will deal only with museum, or art, pottery. Artifacts used for purely utilitarian purposes are discussed in articles such as AFRICAN ARTS.

Kinds, processes, and techniques

Clay and firing

Clay, the basic material of pottery, has two distinctive characteristics: it is plastic (*i.e.*, it can be molded and will retain the shape imposed upon it); and it hardens on firing to form a brittle but otherwise virtually indestructible material that is not attacked by any of the agents that corrode metals or organic materials. Firing also protects the clay body against the effects of water. If a sun-dried clay vessel is filled with water, it will eventually collapse, but, if it is heated, chemical changes that begin to take place at about 900° F (500° C) preclude a return to the plastic state no matter how much water is later in contact with it. Clay is a refractory substance; it will vitrify only at temperatures of about 2,900° F (1,600° C). If it is mixed with a substance that will vitrify at a lower temperature (about 2,200° F, or 1,200° C) and the mixture is subjected to heat of this order, the clay will hold the object in shape while the other substance vitrifies. This forms a nonporous, opaque body known as stoneware. When feldspar or soapstone (steatite) is added to the clay and exposed to a temperature of 2,000° to 2,650° F (1,100° to 1,450° C), the product becomes translucent and is known as porcelain. In this section, earthenware is used to denote all pottery substances that are not vitrified and are therefore slightly porous and coarser than vitrified materials.

The line of demarcation between the two classes of vitrified materials—stoneware and porcelain—is extremely vague. In the Western world, porcelain is usually defined as a translucent substance—when held to the light most porcelain does have this property—and stoneware is regarded as partially vitrified material that is not translucent. The Chinese, on the other hand, define porcelain as any ceramic material that will give a ringing tone when tapped. None of these definitions is completely satisfactory: for instance, some thinly potted stonewares are slightly translucent if they have been fired at a high temperature, whereas some heavily potted porcelains are opaque. Therefore, the application of the terms is often a matter of personal preference and should be regarded as descriptive, not definitive.

KINDS OF POTTERY

Earthenware. Earthenware was the first kind of pottery made, dating back about 9,000 years. In the 20th century, it is still widely used.

The earthenware body varies in colour from buff to dark red and from gray to black (see below *Firing*). The body can be covered or decorated with slip (a mixture of clay and water in a creamlike consistency, used for adhesive and casting as well as for decoration), with a clear glaze, or with an opaque tin glaze. Tin-glazed earthenware is usually called maiolica, faience, or delft (see below *Decorative glazing*). If the clear-glazed earthenware body is a cream colour, it is called creamware. Much of the commercial earthenware produced in the second half of the 20th century is heat- and cold-proof and can thus be used for cooking and freezing as well as for serving.

Stoneware. Stoneware is very hard and, although sometimes translucent, usually opaque. The colour of the body varies considerably; it can be red, brown, gray, white, or black.

Fine white stoneware was made in China as early as 1400 BC (Shang dynasty). In Korea, stoneware was first made during the Silla dynasty (57 BC–AD 935); in Japan, during the 13th century (Kamakura period). The first production of stoneware in Europe was in 16th-century Germany. When tea was first imported to Europe from China in the 17th century, each chest was accompanied by a red stoneware pot made at the I-hsing kilns in Kiang-su province. This ware was copied in Germany, the Netherlands, and England. At the end of the 17th century, English potters made a salt-glazed white stoneware that was regarded by them as a substitute for porcelain (see below *Decorative glazing*). In the 18th century, the Englishman Josiah Wedgwood made a black stoneware called basaltes and a white stoneware (coloured with metallic oxides) called jasper. A fine white stoneware, called Ironstone china, was introduced in England early in the 19th century. In the 20th century, stoneware is used mostly by artist-potters, such as Bernard Leach and his followers.

The first porcelain

Porcelain. Porcelain was first made in a primitive form in China during the T'ang dynasty (AD 618–907). The kind most familiar in the West was not manufactured until the Yüan dynasty (AD 1279–1368). It was made from kaolin (white china clay) and petuntse (a feldspathic rock), the latter being ground to powder and mixed with the clay. During the firing, which took place at a temperature of

about 2,650° F (1,450° C), the petuntse vitrified, while the refractory clay ensured that the vessel retained its shape.

In medieval times isolated specimens of Chinese porcelain found their way to Europe, where they were much prized, principally because of their translucency. European potters made numerous attempts to imitate them, and, since at that time there was no exact body of chemical and physical knowledge whereby the porcelain could be analyzed and then synthesized, experiments proceeded strictly by analogy. The only manufactured translucent substance then known was glass, and it was perhaps inevitable that glass made opaque with tin oxide (the German *Milchglas*, or milk glass, for example) should have been used as a substitute for porcelain. The nature of glass, however, made it impossible to shape it by any of the means used by the potter, and a mixture of clay and ground glass was eventually tried. Porcelain made in this way resembles that of the Chinese only superficially and is always termed soft, or artificial, porcelain. The date and place of the first attempt to make soft porcelain are debatable, but some Middle Eastern pottery of the 12th century was made from glaze material mixed with clay and is occasionally translucent (see below *Islāmic pottery: Egypt*). Much the same formula was employed with a measure of success in Florence about 1575 at workshops under the patronage of Duke Francesco de'Medici. No further attempts of any kind appear to have been made until the mid-17th century, when Claude and François Révérend, Paris importers of Dutch pottery, were granted a monopoly of porcelain manufacture in France. It is not known whether they succeeded in making it or not, but, certainly by the end of the 17th century, porcelain was being made in quantity, this time by a factory at Saint-Cloud, near Paris.

The secret of true, or hard, porcelain similar to that of China was not discovered until about 1707 in Saxony, when Ehrenfried Walter von Tschirnhaus, assisted by an alchemist called Johann Friedrich Böttger, substituted ground feldspathic rock for the ground glass in the soft porcelain formula. Soft porcelain, always regarded as a substitute for hard porcelain, was progressively discontinued because it was uneconomic; kiln wastage was excessive, occasionally rising to nine-tenths of the total.

Hard and soft porcelain

The terms soft and hard porcelain refer to the soft firing (about 2,200° F, or 1,200° C) necessary for the first, and the hard firing (about 2,650° F, or 1,450° C) necessary for the second. By coincidence they apply also to the physical properties of the two substances: for example, soft porcelain can be cut with a file, whereas hard porcelain cannot. This is sometimes used as a test for the nature of the body.

In the course of experiments in England during the 18th century, a type of soft porcelain was made in which bone ash (a calcium phosphate made by roasting the bones of cattle and grinding them to a fine powder) was added to the ground glass. Josiah Spode the Second later added this bone ash to the true, hard porcelain formula, and the resulting body, known as bone china, has since become the standard English porcelain. Hard porcelain is strong, but its vitreous nature causes it to chip fairly easily and, unless especially treated, it is usually tinged slightly with blue or gray. Bone china is slightly easier to manufacture. It is strong, does not chip easily, and the bone ash confers an ivory-white appearance widely regarded as desirable. Generally, bone china is most popular for table services in England and the United States, while hard porcelain is preferred on the European continent.

FORMING PROCESSES AND TECHNIQUES

Raw clay consists primarily of true clay particles and undecomposed feldspar mixed with other components of the igneous rocks from which it was derived, usually appreciable quantities of quartz and small quantities of mica, iron oxides, and other substances. The composition and thus the behaviour and plasticity of clays from different sources are therefore slightly different. Except for coarse earthenwares, which can be made from clay as it is found in the earth, pottery is made from special clays plus other materials mixed to achieve the desired results. The mixture is called the clay body, or batch.

To prepare the batch, the ingredients are combined with water and reduced to the desired degree of fineness. The surplus water is then removed.

Shaping the clay. The earliest vessels were modelled by hand, using the finger and thumb, a method employed still by the Japanese to make *raku* teabowls. Flat slabs of clay luted together (using clay slip as an adhesive) were employed to make square or oblong vessels, and the slabs could be formed into a cylinder and provided with a flat base by the same means. Coiled pottery was an early development. Long rolls of clay were coiled in a circle, layer upon layer, until the approximate shape had been attained; the walls of the vessel were then finished by scraping and smoothing. Some remarkably fine early pots were made in this way.

Introduction of the potter's wheel

It is impossible to say when the potter's wheel, which is a difficult tool and needs long apprenticeship, was introduced. A pot cannot be made by hand modelling or coiling without the potter either turning it or moving around it, and, as turning involves the least expenditure of human effort, it would obviously be preferred. The development of the slow, or hand-turned, wheel as an adjunct to pottery manufacture led eventually to the introduction of the kick wheel, rotated by foot, which became the potter's principal tool. The potter throws the clay onto a rapidly rotating disc and shapes his pot by manipulating it with both hands. This is a considerable feat of manual dexterity that leads to much greater exactness and symmetry of form. Perhaps the most skillful of all potters have been the Chinese. Excellent examples of their virtuosity are the double-gourd vases, made from the 16th century onward, which were turned in separate sections and afterward joined together. By the 18th century the wheel was no longer turned by the potter's foot but by small boys, and since the 19th century the motive power has been mechanical.

Jollying, or jiggering, is the mechanical adaptation of wheel throwing and is used where mass production or duplication of the same shape—particularly cups and plates—is required. The jolly, or jigger, was introduced during the 18th century. It is similar to the wheel in appearance except that the head consists of a plaster mold shaped like the inside of an object, such as a plate. As it revolves, the interior of the plate is shaped by pressing the clay against the head, while the exterior, including the footring, is shaped by a profile (a flat piece of metal cut to the contour of the underside of the plate) brought into contact with the clay. Machines that make both cups and plates automatically on this principle were introduced in the 20th century. Small parts, such as cup handles, are made separately by pressing clay into molds and are subsequently attached to the vessel by luting.

Molding

One of the earliest methods of shaping clay was molding. Pots were made by smearing clay around the inside of a basket or coarsely woven sack. The matrix was consumed during firing, leaving the finished pot with the impression of the weave on the exterior. A more advanced method, used by the Greeks and others, is to press the pottery body into molds of fired clay. Though the early molds were comparatively simple, they later became more complex, a tendency best seen in those molds used for the manufacture of pottery figures. The unglazed earthenware figures of Tanagra (Boeotia, central Greece) were first modelled by hand, then molds of whole figures were used, and finally the components—arms, legs, heads, and torsos—were all molded separately. The parts were often regarded as interchangeable, so that a variety of models could be constructed from a limited number of components. No improvement on this method of manufacture had been devised by the 20th century: the European porcelain factories make their figures in precisely the same way.

Plaster of paris molds were introduced into Staffordshire about 1745. They enabled vessels to be cast in slip, for when the slip was poured into the mold the plaster absorbed the water from it, thus leaving a layer of clay on the surface of the mold. When this layer had reached a sufficient strength and thickness, the surplus slip was poured off, the cast removed and fired, and the mold used again. This method is still in common use.

Drying, turning, and firing. Newly shaped articles were

formerly allowed to dry slowly in the atmosphere. In 20th century pottery factories, this stage is speeded up by the introduction of automatic dryers, often in the form of hot, dry tunnels through which the ware passes on a conveyor belt.

Turning is the process of finishing the greenware (unfired ware) after it has dried to leather hardness. The technique is used to smooth and finish footrings on wheel-thrown wares or undercut places on molded or jiggered pieces. It is usually done on the potter's wheel or jigger as the ware revolves. Lathe turning, like most hand operations, was tending to disappear in the mid-20th century except on the more ornamental and expensive objects.

The firing process

The earliest vessels, which were sun-dried but not fired, could be used only for storing cereals and similar dry materials. If a sun-dried clay vessel is filled with water it absorbs the liquid, becomes very soft, and eventually collapses; but if it is heated, chemical changes that begin to take place at about 900° F (500° C) preclude a return to the plastic state.

After thorough drying, the pottery is fired in a kiln. In primitive pottery making, the objects were simply stacked in a shallow depression or hole in the ground, and a pyre of wood was built over them. Later, coal- or wood-fired ovens became almost universal. In the 20th century both gas and electricity are used as fuels. Many improvements have been made in the design of intermittent kilns, in which the ware is stacked when cold and then raised to the desired temperature. These kilns are extravagant of fuel, however, and are awkward to fill or empty if they have not had time to cool completely. For these reasons they are being replaced by continuous kilns, the most economical and successful of which is the tunnel kiln. The wares are conveyed slowly from a comparatively cool region at the entrance to the full heat in the centre. As they near the exit after firing, they cool gradually.

The atmosphere in the kiln at the time of firing, as well as the composition of the clay body, determines the colour of the fired earthenware pot. Iron is ubiquitous in earthenware clay, and under the usual firing conditions it oxidizes, giving a colour ranging from buff to dark red according to the amount present. In a reducing atmosphere (*i.e.*, one where a limited supply of air causes the presence of carbon monoxide) the iron gives a colour varying from gray to black, although a dark colour may also occur as a result of the action of smoke. Both of the colours that result from iron in the clay can be seen in the black-topped vases of predynastic Egypt.

DECORATING PROCESSES AND TECHNIQUES

Impressing and stamping. Even the earliest pottery was usually embellished in one way or another. One of the earliest methods of decoration was impressing the raw clay. Finger marks were sometimes used, as well as impressions from rope (Japanese Jōmon ware of the 1st millennium BC) or from a beater bound with straw (used to shape the pot in conjunction with a pad held inside it). Basketwork patterns are found on pots molded over baskets and are sometimes imitated on pots made by other methods.

Relief decoration

The addition of separately modelled decoration, known as applied ornament (or appliqué), such as knops (ornamental knobs) or the reliefs on Wedgwood jasperware, came somewhat later. The earliest known examples are found on Mediterranean pottery made at the beginning of the 1st millennium. Raised designs are also produced by pressing out the wall of the vessel from inside, as in the Roman pottery known as terra sigillata, a technique that resembles the repoussé method adopted by metalworkers. Relief ornament was also executed—by the Etruscans, for example—by rolling a cylinder with the design recessed in intaglio over the soft clay, the principle being the same as that used to make Babylonian cylinder seals.

Incising, sgraffito, carving, and piercing. The most primitive kind of decoration is that which is incised into the raw clay with a pointed stick or with the thumbnail, chevrons (inverted v's) being a particularly common motif. Incised designs on a dark body are sometimes filled with lime, which effectively accents the decoration. Examples can be seen in some early work from Cyprus and in some comparatively modern work from primitive tribes. Decoration that has been engraved after firing is much less usual, but the skillful and accomplished engraving on one fine Egyptian pot of the predynastic period (*i.e.*, before *c.* 3100 BC) suggests that the practice may have been more frequent than was previously suspected.

Originally, defects of body colour suggested the use of slip, either white or coloured, as a wash over the vessel before firing. A common mode of decoration is to incise a pattern through the slip, revealing the differently coloured body beneath, a technique called sgraffito ("scratched"). Sgraffito ware was produced by Islāmic potters and became common throughout the Middle East. The 18th-century scratched-blue class of English white stoneware is decorated with sgraffito patterns usually touched with blue.

Sgraffito technique

Related to the sgraffito technique is slip carving: the clay body is covered with a thick coating of slip, which is carved out with a knife, leaving a raised design in slip (champlevé technique). Slip carving was done by Islāmic and Chinese potters (Sung dynasty).

Much pierced work—executed by piercing the thrown pot before firing—was done in China during the Ming dynasty (reign of Wan-li). It was sometimes called "demon's work" (*kuei kung*) because of the almost supernatural skill it was supposed to require. English white molded stoneware of the 18th century also has elaborate piercing.

Slip decorating. In addition to sgraffito and carving, slip can be used for painting, trailing, combining, and inlay. The earliest forms of decoration in ancient Egypt, for example, were animal and scenic motifs painted in white slip on a red body; and in the North American Indian cultures coloured slips provided the material for much of the painted freehand decoration.

Slip, too, is sometimes dotted and trailed in much the same way as a confectioner decorates a cake with icing sugar; the English slipwares of the 17th and 18th centuries are typical of this kind of work. Earthenware washed over with a white slip and covered with a colourless glaze is sometimes difficult to distinguish from ware covered with a tin glaze (see below *Decorative glazing*). In consequence it has sometimes been wrongly called faience. The term for French earthenware covered with a transparent glaze (in imitation of Wedgwood's creamware) is *faience fine*, and in Germany it is called *Steingut*. *Mezza-Maiolica* (Italy) and *Halb fayence* (Germany) refer to slip-covered earthenware with incised decoration.

Slip is also used for combed wares. The marbled effect on Chinese pottery of the T'ang dynasty, for example, was sometimes achieved by mingling, with a comb, slips of contrasting colours after they had been put on the pot.

Combed wares and inlay

The Koreans used slip for their inlay technique called *mishima*. The designs were first incised into the clay, and the incisions were then filled with black and white slip.

Burnishing and polishing. When the clay used in early pottery was exceptionally fine, it was sometimes polished or burnished after firing. Such pottery—dating back to 6500 and 2000 BC—has been excavated in Turkey and the Pan-shan cemetery in Manchuria. Most Inca pottery is red polished ware.

Decorative glazing. Early fired earthenware vessels held water, but, because they were still slightly porous, the liquid percolated slowly to the outside where it evaporated, cooling the contents of the vessel. Thus, the porosity of earthenware was, and still is, sometimes an advantage in hot countries, and the principle is utilized in the 20th century in the construction of domestic milk and butter coolers and some food-storage cupboards.

Porosity, however, had many disadvantages—*e.g.*, the vessels could not be used for storing wine or milk. To overcome the porosity, primitive peoples often applied varnishes of one kind or another. Varnished pots were made, for example, in Fiji. The more advanced technique is glazing. The fired object was covered with a finely ground glass powder often suspended in water and was then fired again. During the firing the fine particles covering the surface fused into an amorphous, glasslike layer, sealing the pores of the clay body.

The art of glazing earthenware for decorative as well as practical purposes followed speedily upon its introduction.

On stoneware, hard porcelain, and some soft porcelain, which are fired to the point of vitrification and are therefore nonporous, glazing is used solely for decoration.

Except for tin-glazed wares (see below *Painting*), earthenware glaze was added to the biscuit clay body, which was then fired a second time at a lower temperature. Soft porcelain glaze was always applied in this way. Hard porcelain glaze was usually (and stoneware salt glaze, always) fired at the same time as the raw clay body at the same high temperature.

Kinds of glazes

Basically, there are four principal kinds of glazes: feldspathic, lead, tin, and salt. (Modern technology has produced new glazes that fall into none of these categories while remaining a type of glass.) Feldspathic, lead, and salt glazes are transparent; tin glaze is an opaque white. Hard porcelain takes a feldspathic glaze, soft porcelain usually a kind of lead glaze and can be classified according to the kind of glaze used.

There are two main types of glazed earthenware: the one is covered with a transparent lead glaze, and the other with an opaque white tin glaze.

Tin glaze was no doubt employed in the first place to hide faults of colour in the body, for most clays contain a variable amount of iron that colours the body from buff to dark red. Tin-glazed wares look somewhat as though they have been covered with thick white paint. These wares are often referred to as "tin-enamelled." As noted above, other terms in common use are maiolica, faience, and delft. Unfortunately, these are variously defined by various authorities. The art of tin-glazing was discovered by the Assyrans, who used it to cover courses of decorated brickwork. It was revived in Mesopotamia about the 9th century AD and spread to Moorish Spain, whence it was conveyed to Italy by way of the island of Majorca, or Maiolica. In Italy, tin-glazed earthenware was called maiolica after the place where it was mistakenly thought to have originated. The wares of Italy, particularly those of Faenza, were much prized abroad, and early in the 16th century the technique was imitated in southern France. The term faience, which is applied to French tin-glazed ware, is undoubtedly derived from Faenza. Wares made in Germany, Spain, and Scandinavia are known by the same name. Early in the 17th century a flourishing industry for the manufacture of tin-glazed ware was established at the town of Delft, Holland, and Dutch potters brought the art of tin-glazing to England together with the name of delft, which now applies to ware manufactured in The Netherlands and England. Some misleading uses of these terms include that of applying maiolica to wares made outside Italy but in the Italian style, and faience to Egyptian blue-glazed ware and certain kinds of Near Eastern earthenware.

Although glazed stoneware does not fall into such definite categories as glazed earthenware, to some extent it can be classified according to the kind of glaze used. The fine Chinese stonewares of the Sung dynasty (AD 960–1279) were covered with a glaze made from feldspar, the same vitrifiable material later used in both the body and glaze of porcelain. Stoneware covered with a lead glaze is sometimes seen, but perhaps the majority of extant glazed wares are salt-glazed. In this process a shovelful of common salt (sodium chloride) is thrown into the kiln when the temperature reaches its maximum. The salt splits into its components, the sodium combining with the silica in the clay to form a smear glaze of sodium silicate, the chlorine escaping through the kiln chimney. Salt glazes have a pitted appearance similar to that of orange peel. A little red lead is sometimes added to the salt, which gives the surface an appearance of being glazed by the more usual means.

Crazed and coloured glaze

Some fusion usually occurs between glaze and body, and it is therefore essential that both should shrink by the same proportion and at the same rate on cooling. If there is a discrepancy, the glaze will either develop a network of fine cracks or will peel off altogether. This crazing of the glaze was sometimes deliberately induced as a decorative device by the Chinese.

One method of applying colour to pottery is to add colouring oxides to the glaze itself. Coloured glazes have been widely used on earthenware, stoneware, and porcelain and have led to the development of special techniques in which patterns were incised, or outlined with clay threads (cloisonné technique), so that differently coloured glazes could be used in the same design without intermingling; for example, in the *lakabi* wares of the Middle East.

Unglazed wares

Earthenware, stoneware, and porcelain are all found in unglazed as well as glazed forms. Wares fired without a glaze are called biscuit. Early earthenware pottery, as discussed above, was unglazed and therefore slightly porous. Of the unglazed stonewares, the most familiar are the Chinese Ming dynasty teapots and similar wares from I-hsing in Kiangsu Province, the red stoneware body made at Meissen in Saxony during the first three decades of the 18th century and revived in modern times, and the ornamental basaltes and jaspers made by Josiah Wedgwood and Sons since the 18th century. Biscuit porcelain was introduced in Europe in the 18th century. It was largely confined to figures, most of which were made at the French factories of Vincennes and Sèvres. Unglazed porcelain must be perfect, for the flaws cannot be concealed with glaze or enamel. The fashion for porcelain biscuit was revived in the 19th century and called Parian ware.

Painting. Painted designs are an early development, some remarkably fine work made before 3000 BC coming from excavations at Ur and elsewhere in Mesopotamia, as well as urns from Pan-shan in Manchuria (Northeast Provinces) that date back to 2000 BC.

The earliest pottery colours appear to have been achieved by using slips stained with various metallic oxides (see above *Slip decoration*). At first these were undoubtedly oxides that occurred naturally in the clay; later they were added from other sources. Until the 19th century, when pottery colours began to be manufactured on an industrial scale, the oxides commonly used were those of tin, cobalt, copper, iron, manganese, and antimony. Tin oxide supplied a useful white, which was also used in making tin glaze (see above *Decorative glazing*) and occasionally for painting. Cobalt blue, ranging in colour from grayish blue to pure sapphire, was widely used in the Far East and Europe for blue-and-white porcelain wares. Cupric oxide gives a distinctive series of blues, cuprous oxide a series of greens, and, in the presence of an excess of carbon monoxide (which the Chinese achieved by throwing wet wood into the kiln), cupric oxide yields a bluish red. This particular colour is known as reduced copper, and the kiln is said to have a reducing atmosphere. (For the effect of this atmosphere on the colour of the biscuit body, see above *Firing*). The colours obtained from ferric iron range from pale yellow to black, the most important being a slightly orange red, referred to as iron red. Ferrous iron yields a green that can be seen at its best on Chinese celadon wares. Manganese gives colours varying from the bright red purple similar to permanganate of potash to a dark purplish brown that can be almost black. The aubergine purple of the Chinese was derived from this oxide. Antimony provides an excellent yellow.

Overglaze and underglaze colours

Pottery colours are used in two ways—under the glaze or over it. Overglaze painting is executed on a fired clay body covered with a fired glaze, underglaze painting, on a fired, unglazed body (which includes a body that has been coated with raw or unfired, glaze material).

Earthenware and stoneware are usually decorated with underglaze colours. After the body is manipulated into the desired shape it is fired. It is then painted, coated with glaze, and fired again. The second firing is at a lower temperature than the first, being just sufficient to fuse the glaze. In the case of most tin-glazed wares the fired object was first coated with the tin glaze, then painted, then fired again. The painting needed exceptional skill, since it was executed on the raw glaze and erasures were impossible. The addition of a transparent lead glaze over the painted decoration needed a third firing. In 18th-century Germany especially tin-glazed wares were decorated with colours applied over the fired glaze, as on porcelain. The wares were sometimes called *Fayence-Porcellaine.*

The body and glaze of most hard porcelain are fired in one operation, since the fusion temperature of body and glaze is roughly the same. Underglaze colours are limited

because they must be fired at the same temperature as the body and glaze, which is so high that many colours would "fire away" and disappear. Although the Chinese made some use of copper red, underglaze painting on porcelain is more or less limited to cobalt blue, an extremely stable and reliable colour that yields satisfactory results under both high- and low-temperature firings. On soft porcelain, manganese was sometimes used under the glaze, but examples are rare. All other porcelain colours were painted over the fired glaze and fixed by a second firing that is much lower than the first.

Underglaze pigments are known as high-temperature colours, or colours of the grand feu. Similarly, overglaze colours are known as low-temperature colours, or colours of the petit feu. Other terms for overglaze colours are enamel colours and muffle colours, the latter name being derived from the type of kiln, known as a muffle kiln, in which they are fired. Overglaze colours consist of pigments mixed with glaze material suspended in a medium, such as gum arabic, with an alkaline flux added to lower the melting point below that of the glaze. They were first used in Persia on earthenware (*minai* painting) in the 12th century and perhaps at the same date on Chinese stoneware made at Tz'u-chou.

Lustre painting, gilding, and silvering

Lustre decoration is carried out by applying a colloid suspension of finely powdered gold, silver, platinum, or copper to the glazed and fired object. On a further, gentle firing, gold yields a purplish colour, silver a pale straw colour, platinum retains its natural hue, and copper varies from lemonish yellow to gold and rich brown. Lustre painting was invented by early Islāmic potters.

Pottery may be gilded or silvered. The earliest gilding was done with gold mixed with an oil base. The use of gold ground in honey may be seen on the finest porcelain from Sèvres during the 18th century, as well as on that from Chelsea. Toward the end of the same century gold was applied as an amalgam, the mercury subsequently being volatilized by heating. Silver was used occasionally for the same purposes as gold but with time has nearly always turned black through oxidation.

Transfer printing. The transfer print made from a copper plate was first used in England in the 18th century. In the 20th century transfers from copper plates are in common use for commercial wares, as are lithographic and other processes, such as silk screen printing, which consists of rubbing the colour through a patterned screen of textile material. Combinations of hand-painted and transfer decorations are often used. The outline or other part of the decoration is put on with a transfer print, then parts of the design, such as leaves, flowers, clothing, or water, are painted in.

MARKING

Most porcelain and much earthenware bears marks or devices for the purpose of identification. Stonewares, apart from those of Wedgwood, are not so often marked. Chinese porcelain marks usually record the dynasty and the name of an emperor, but great caution is necessary before accepting them at their face value. The Chinese frequently used the mark of an earlier reign as a sign of veneration for the products of antiquity and, in recent times, for financial gain.

The majority of European factories adopted a device—for example, the well-known crossed swords of Meissen taken from the electoral arms of Saxony, or the royal monogram on Sèvres porcelain—but these, also, cannot be regarded as a guarantee of authenticity. Not only are false marks added to contemporary forgeries but the smaller 18th-century factories often copied the marks of their more august competitors. If 18th-century European porcelain is signed with the artist's name, it generally means that the painting was done outside the factory. Permission to sign factory work was rarely given.

On earthenware, a factory mark is much less usual than on porcelain. Workmen's marks of one kind or another are frequently seen, but signatures are rare. There are a few on Greek vases.

It is often desirable to identify the provenance and the date of manufacture of specimens of pottery as closely as possible. Not only does such information add to the interest of the specimen in question and increase understanding of the pottery art as a whole but it also often throws fresh light on historical questions or the social habits and technical skills of the time it was made. Since ceramics are not affected by any of the agents that attack metal, wood, or textiles, they are often found virtually unchanged after being buried for thousands of years, while other artifacts from the same period are partially or completely destroyed. For this reason archaeologists use pottery extensively; for example, to trace contacts between peoples, since vessels were often widely distributed in course of trade, either by the people who made them or by such maritime nations as the Phoenicians.

Archaeologists' use of pottery

Pottery making is not universal. It is rarely found among nomadic tribes, since potters must live within reach of their raw materials. Moreover, if there are gourds, skins, and similar natural materials that can be made into vessels without trouble, there is no incentive to make pottery. Yet pottery making is one of the most widespread and oldest of the crafts.

Western pottery

ANCIENT NEAR EAST AND EGYPT

In the early 1960s, excavations at a Neolithic settlement at Çatalhüyük, on the Anatolian Plateau of Turkey, revealed a variety of crude, soft earthenware estimated to be approximately 9,000 years old. A more advanced variety of handmade pottery, hardfired and burnished, has proved to be as early as 6500 BC. The use of a red slip covering and molded ornament came a little later.

Handmade pottery has been found at Ur, in Mesopotamia, below the clay termed the Flood deposit. Immediately above the Flood deposit, and therefore dating from a time soon after the Flood (about 3000 BC), was wheelmade decorated pottery of a type usually called Al 'Ubaid. Perhaps the most richly decorated pottery of the Near East, remarkable for its fine painting, comes from Susa (Shushan) in southwest Iran. The motifs are partly geometric, partly stylized but easily recognizable representations of waterfowl and running dogs, usually in friezes. They are generally executed in dark colours on a light ground. Vases, bowls, bowls on feet, and goblets have been found, all dating from about 3200 BC. By 3000 BC pottery was no longer decorated. Earthenware statuettes belong to this period, and a vessel (in the Louvre, Paris) with a long spout based on a copper prototype is the ancestor of many much later variations from this region in both pottery and metal.

Remarkable glazed brick panels have been recovered from the ruins of Khorsabad (Dur Sharrukin), Nimrūd (Calah), Susa, and Babylon. They provide the first instance of the use of tin glaze; although the date of its introduction cannot be certainly determined. A well-known fragment from Nimrūd in the British Museum belongs to about 890 BC, and by the 5th century BC extremely large friezes, one of them about 11 yards (10 metres) long, were being erected at Susa. The presence of lead in the blue glazes derived from copper suggests that the lead may have been added deliberately as a flux, and that this glazing technique, like that of tin-glazing, subsequently was forgotten—to be recovered only at a much later date.

First use of tin glaze

In Egypt, pottery was made in great variety in the predynastic period (up to *c.* 3100 BC), and a hard-fired ware of good quality was attained. The earliest forms of decoration were geometrical or stylized animal or scenic motifs painted in white slip on a red body. There is comparatively little variation until the 26th dynasty (*c.* 664–525 BC), when clay was probably imported from Greece. Most artifacts are vessels of one kind or another, although pottery figures of variable quality were made, some of the later examples (after 500 BC) showing signs of Greek influence.

The so-called faience of Egypt is an unfired ware and thus, strictly speaking, falls outside the definition of pottery used in this article. As early as the 1st dynasty, figures, vases, and tiles of this material were covered with a fired glaze that was coloured turquoise and green with copper oxide. Later, the colouring materials common to

the Egyptian glassmaker, including cobalt and manganese, were added.

ANCIENT AEGEAN AND GREECE

The potter's art first reached the Aegean in the Neolithic, or New Stone Age. All Neolithic vases are handmade, and the best are highly polished; in other respects, the various local schools have little in common, since communications were severely limited in this remote period. The main centres of pottery production lay in Thessaly and Crete. Thessalian potters favoured a red monochrome ware but occasionally attempted simple painted decoration consisting of rectilinear patterns, with a vertical or diagonal emphasis. The Neolithic pottery of Crete is remarkable for its finely burnished surface, any decoration usually incised.

Bronze Age. *Early Bronze Age (c. 3000–2000 BC).* On the mainland, the pottery initiative passed from Thessaly to the Peloponnese and Boeotia. Early Bronze Age pottery from these two areas has been classified into Early, Middle, and Late Helladic, each subdivided into stages I, II, and III. Early Helladic wares show how quickly pottery fell under the influence of the new craft of metalworking: the two leading shapes, the sauceboat and the high-spouted jug, both have metal prototypes. Painted ornament is rare before the final stage (Early Helladic III, or EH III); in the central phase (EH II), the surface is coated with a dark pigment formed from a solution of the clay. This type of paint, later much improved by the Athenians (see below *Attic black figure and red figure*), remained the normal medium of decoration on all Aegean pottery until the adoption of a true silicate glaze in Byzantine times.

Influence of metal working

The contemporary wares of the Cyclades are similar, but more use is made of incised ornament; spirals are common motifs, while some vases bear primitive representations of ships. The pottery of Early Minoan Crete bears simple geometrical patterns, at first in dark paint on a light clay ground (EM I–II), and subsequently in white over a coat of dark paint (EM III). The surface of the ware of Vasíliki in eastern Crete (EM II) has a mottled red and black appearance. The commonest Early Minoan shapes are high-spouted jugs and long-spouted drinking jars resembling teapots.

Middle Bronze Age (c. 2000–1500 BC). After the conquest of the mainland by the first Greeks in the Middle Bronze Age, the local schools of pottery developed on widely different lines. The Minyan ware introduced by the newcomers in an unpainted monochrome body thrown on a fast wheel and fired in a reducing kiln to a uniform gray colour that penetrates the biscuit; the surface is then highly polished and feels soapy to the touch. The shapes are all strongly ridged (carinated) and probably derive from metalwork.

Equally characteristic of this period are the mat-painted wares, which are mainly handmade: here rectilinear patterns are applied in dull black or lilac to a porous white surface. This style, although native to the Cyclades, was also widely imitated on the mainland; in the latest stage the ornament falls increasingly under the influence of the polychrome and curvilinear style of Middle Minoan Crete.

Pottery of Crete

By far the most sophisticated pottery of this epoch was made in Crete, contemporaneously with the first palaces at Knossos and Phaistos. The finest ware (Middle Minoan II) is confined to these two royal capitals and to the Kamáres cave sanctuary whence the style derives its name (Figure 117). Over a dark lustrous ground the ornament is added in red and white, the carefully composed designs striking a subtle balance between curvilinear abstract patterns and stylized motifs derived from plant and marine life. The decoration sometimes takes the form of appliqué molded ornament or barbotine (made of slip) knobs. By the time of MM II the use of the fast wheel had become general, imparting a new crispness to the profiles. Among the commonest shapes are carinated cups (often of eggshell thinness), small, round jars with bridge-spouts, and large storage jars (pithoi). In the course of MM III the fashion for polychrome schemes gradually died out, but at the very end of the period (MM III B) a new naturalistic style was born, inspired by the floral and marine frescoes on

the walls of the second palaces. The wide distribution of MM pottery illustrates the vigour of Cretan commercial enterprise; several Minoan emporia were founded in the Aegean Islands, while exports also reached Cyprus, Egypt, and the Levant.

Late Bronze Age (c. 1580–1100 BC). Aegean civilization now reached new heights of prosperity, displayed in the luxurious life of the Minoan palaces and the splendid treasures of the shaft graves at Mycenae. Potters were much influenced by work in richer and more spectacular media: many of their shapes can be traced to originals in gold and bronze found in Cretan palaces and Mycenaean tombs,adapted to the shape of the vase.

With the spread of Minoan culture around the shores of the Aegean, Cretan potters exercised a profound influence on the other local schools, and for the first two centuries of this period the vases of the mainland (known as Late Helladic or Mycenaean) are closely related to Minoan models. In the 16th century BC (LM I A), Cretan potters reversed their colour scheme, returning to dark-on-light decoration. Their repertoire includes some abstract motifs (*e.g.*, running spirals and vertical ripples) but is mainly derived from nature, a continuation of the figurative style of MM III B: flowers, grasses, and olive sprays are drawn with charm and spontaneity. After 1500 BC (LM I B) marine creatures are much in evidence, rendered with considerable realism: in a setting of coral and seaweed may be found argonauts, starfish, dolphins, and, above all, the octopus, wrapping his tentacles round the vase. On the palace style amphorae of the late 15th century BC (LM II), however, there is a reaction against this extreme naturalism: plants and marine life continue, but in a more stylized and symmetrical form.

After the destruction of Knossos in *c.* 1400 BC, the artistic initiative passed to Mycenae and remained there until the end of the Bronze Age. In the 14th and 13th centuries BC (LH III A and B), Mycenaen vases were widely exported, not only to Egypt and the Levant but also as far west as Italy and Sicily. In the interests of commerce, pottery was mass-produced, and the Mycenaean colonies on Rhodes and Cyprus were as prolific as the mainland. Some shapes, like the stirrup-vase, were imported for their contents of oil and unguents; others, such as the tall stemmed goblets, were prized for the excellence of their form. Yet, in spite of their high technical standards, the decoration shows a lack of invention. In the absence of any new ideas, the old floral and marine motifs were subjected to an ever-increasing degree of stylization: the flowers degenerate into chevrons and dashes, the octopus into wavy lines. At the same time there is a new tendency to concentrate the decoration into a single focal zone, in anticipation of later Greek pottery. A few large jars bear crude representations of human figures in chariot scenes, probably derived from palace frescoes. (No less schematic are the painted female figurines found in tombs and shrines of this period.) In

the pottery of the 12th century BC, which saw the collapse of Mycenaean civilization (LH III C), there is an abrupt decline in quality as well as in artistic imagination.

Proto-geometric and geometric styles

Early Iron Age. Pottery was the first art to recover its standards after the Dorian invasion and the overthrow of Mycenae. Athens escaped these disasters and in the ensuing dark age became the chief source of ceramic ideas. For a short time Mycenaean motifs survived in debased form but on new shapes. This Submycenaean ware soon gave place to the style known as Protogeometric (*c.* 1100–900 BC) by a natural process of evolution that converted the decaying Mycenaean ornament into regular geometrical patterns; thus, the slovenly spirals were transformed into neat sets of concentric circles, always drawn with a compass fitted with a multiple brush. These circles are the hallmark of Protogeometric decoration, which, like the latest Mycenaean, is confined to the handle zone; in the final stage the rest of the surface is covered with a thick black paint remarkable for its high lustre. Many shapes were inherited from Submycenaean, but all were tautened and vastly improved: the drinking vessels rest on high conical feet, while the closed vases have graceful ovoid bodies. After its invention in Attica, the Protogeometric style spread to other parts of the Aegean world.

Geometric style. In the early 9th century BC Athenian potters introduced the full Geometric style by abandoning circular for rectilinear ornament, the key meander assuming the leading role. At first decoration was restricted to a small reserved area surrounded by the lustrous dark paint; later, as the style approached maturity, more decorated zones were added, until the potter achieved a harmonious balance between light and dark. In the 8th century, after nearly 400 years of abstract decoration, living creatures appear once again, although their style is hardly less angular than the geometric ornament that supports them. Geometric pottery reached its fullest development in the gigantic amphorae and kraters that served as grave monuments in the Athenian Dipylon cemetery; here a funerary scene, showing the corpse on the bier surrounded by mourners, occupies the main panel, while other friezes contain chariot processions, battles on land and sea, rows of animals, and linear geometric designs. The creators of these monumental vases established a continuous tradition of figured painting that persisted on Greek pottery until the end of the Classical period; the immediate consequence of their innovation was a loss of interest in purely abstract design, which became increasingly perfunctory on the latest Geometric vases.

Period of Oriental influence (c. 725–c. 600 BC). After several centuries of isolation, the renewal of contact with the Middle East provided a welcome stimulus to the Greek potter. In art, as well as in commerce, it was Corinth that now led the way. Unlike the Athenians, Corinthian potters specialized in small vases and especially in the tiny aryballos, or scent bottle, which found a ready market throughout the Mediterranean region. There soon arose a style of miniatures that was called Proto-Corinthian; it borrowed much of its repertoire from the fauna and flora of Syrophoenician art. Processions of animals, both real and legendary, are placed in the main friezes, while lotus flowers and palmettes serve as subsidiary ornament. When human beings are depicted, mythical scenes can often be recognized, reflecting the early diffusion of Homeric epic poetry. It was on Proto-Corinthian vases that the technique known as black-figure was first applied: the figures were first drawn in black silhouette and were then marked with incised detail; further touches were added in purple and white.

First use of black-figure technique

Other notable Orientalizing styles arose in Attica, the Cyclades, Laconia, and Rhodes, regional differences in pottery becoming more clearly marked as the Hellenic city-states grew into self-conscious political units. The Athenians still did their best work on large funerary vases. At first they cultivated a wild and grandiose manner in which the figures of men and animals were elaborated in outline; later, incised ornament introduced from Corinth imposed a salutary discipline. Cycladic potters also attempted the grand manner; Laconian work, on the other hand, is confined to a small scale and owes comparatively little to Oriental influence. The Rhodians rarely progressed beyond animal friezes drawn in outline; their style is known as "wild goat", after their favourite quadruped.

Attic black-figure and red-figure. *Archaic period (c. 750–c. 480 BC).* By *c.* 550 BC Athens had once again become the principal centre of pottery manufacture in Greece, having ousted its Corinthian rivals from the overseas markets. Its success is at least partially due to a sudden improvement in technique, for its potters had learned how to obtain the familiar orange-red surface of their vases by mixing a proportion of ruddle, or red ochre, with their clay. As the main medium of decoration, the Athenians perfected a shiny black pigment that was more lustrous than anything that had been hitherto achieved.

In these centuries most of the more important vases were painted either in the black-figure or in the slightly later red-figure technique, so that some explanation of the essential difference is necessary. The red-figure style can be compared with a photographic print, the black-figure with a negative. The latter figures were painted in silhouette in glossy black pigment on the orange-red polished surface. Details were indicated by incised lines and by the occasional use of white and purple, the female figure, especially, being painted in white. Decoration on the red-figure vases was first outlined in black; the surface outside of the outline was then completely covered by the black pigment, leaving the figures reserved in red. Details were added in black, and in dilutions of the black pigment that appear as brown; purple is occasionally found at first but dies out in mature red-figure work. The use of white was revived on the gaudier vases of the 4th century, where yellow brown, gold, and even blue are sometimes used. The forms of Attic black- and red-figure, in the course of centuries, were limited to certain well-defined types, such as the amphora, kylix, krater, and hydria.

Difference between black- and red-figure techniques

The practice of signing vases, already begun in the 7th century, became more common in the 6th. The signatures record either the potter or the painter or in some cases both. The inscription on the celebrated François Vase in the Museo Archeologico in Florence—"Ergotimos made me; Cleitias painted me"—supplies the first positive evidence that, with only occasional exceptions, the two functions had become separate. When the name of a recognizable painter is not known from an inscription, it has become the fashion to name him after the potter with

whom he usually worked: thus, the "Amasis painter" is the habitual colleague of Amasis the potter.

The Attic black-figure style was well developed by the beginning of the 6th century. Among the most favoured subjects were the Labours of Heracles, Theseus, and the revels of Dionysus with his attendant train of satyrs and maenads. The finest Attic black-figure vases were made between 550 and 520 BC, the figures being rendered in a mature Archaic style much influenced by contemporary developments in sculpture. This is the generation of Exekias, the greatest master of the technique (Figure 118). He excelled in painting and in finely engraved detail; he also succeeded, where others had failed, in endowing his figures with mood and emotion, as well as the capacity for action. With Exekias the possibilities of black-figure were virtually exhausted, and after the introduction of red-figure (*c.* 530 BC) it is not surprising that the best artists soon turned to this new technique, which allowed a greater freedom of expression and more naturalistic treatment of the human body. After *c.* 500 BC the only important vases in black-figure are the amphoras presented to victors at the Panathenaic Festival; these have a figure of Athena standing between two pillars and are usually inscribed "I am one of the prizes from Athens."

Early red-figure artists

The early red-figure artists were not slow to exploit the advantages of the new system. Benefitting from the experience of relief sculptors, they had mastered the problems of foreshortening by the end of the 6th century; but since they still avoided any suggestion of depth in their grouping, they were able to convey the illusion of a third dimension without doing violence to the two-dimensional surface of the vase. The most successful work was done in the final years of the Archaic period (*c.* 500–*c.* 480 BC) when the style of the figures, with their formal and elaborate patterns of drapery, was still decorative rather than naturalistic. Monotony was avoided through the use of a wide variety of poses and simple devices for rendering character and mood. Besides the old heroic and Dionysiac themes, many scenes from daily life (especially orgiastic banquets) were now being used (Figure 119).

Classical period (c. 480–c. 330 BC). This period saw a progressive decline in Attic vase painting. Because of the limitations imposed by the pot surface, the vase painter could no longer keep pace with the rapid advance toward naturalism in the major arts; the occasional attempts at perspective and depth of grouping simply detracted from the shape of the vessel (a mistake repeated in some painting on Italian maiolica in the late 16th century AD). Furthermore, in contrast with the earlier wares, much of the later Attic vase painting shows a saccharine sentimentality and triviality in both the choice of subject and its treatment. Distinguished exceptions are the funerary lekythoi of the late 5th century, decorated in subdued mat colours on a white background. The figures on these vases, isolated and statuesque, share the serenity and restraint of the Parthenon sculptures and suggest something of the grandeur of classical free painting, nearly all of which is now lost. In the 4th century, the figured decoration of pottery had become a degenerate art, and by *c.* 320 BC it had died out in Attica.

In addition to their black- and red-figure vases, the Athenians manufactured plain black-painted wares in great quantity; these follow the shapes of the figured pottery.

Hellenistic period (c. 330–c. 30 BC). After the end of red-figure, Greek pottery is undistinguished. Painted decoration is virtually limited to festoons of ivy, laurel, and a vine in white or yellow over a black ground; the black pigment loses its lustrous sheen and assumes a dull metallic texture. A class of hemispherical bowls, known as Megarian, was made in molds and bears relief decoration in imitation of metal bowls. More remarkable are the contemporary terra-cotta figurines; among the most accomplished are the draped women from Tanagra in Boeotia, whose artistic value is sometimes marred by excessive sentimentality.

ETRUSCAN AND ROMAN

Etruria. At the beginning of the Iron Age (*c.* 900 BC), the most characteristic vessel of the Villanovan culture is the cremation urn. It is usually biconical in shape but sometimes takes the form of a primitive hut, decorated with quasi-architectural ornament in relief.

The first pottery of importance is the Etruscan ware called *bucchero,* which was fired in a reducing kiln. The earliest examples of the 8th century BC, for which the wheel was rarely used, were decorated with incised or engraved geometric patterns. By the 6th century lively and stylized birds and animals were engraved, modelled, or applied in friezes or in conjunction with such geometric patterns as re-entrant (coiling inward) spirals (Figure 120). Later, relief ornament was often executed by rolling a cylinder with design recessed in intaglio over the soft clay, the principle being the same as that used to make Babylonian cylinder seals. Vases with covers in the form of a human head, with arms slipped through fixed ring handles, were made for funerary purposes until about the mid-6th century.

In the late Archaic period the Etruscans excelled in life-size terra-cotta sculptures, of which the outstanding examples are the menacing figure of Apollo, from his temple at Veii, and the large sarcophagi from Caere, with couples of banqueters reclining on the lid. Figures, heads, and busts continued to be produced in the Hellenistic period.

Greek influence

Proto-Corinthian ware was copied with great exactness by Greek colonists as early as 700 BC at Cumae, near Naples. The Etruscans soon learned to use the Greek black pigment, and stylized human and animal figures appear in red, black, and white on a light clay or on the *bucchero* surface. Copies of the black-figure vases were soon so accomplished that it is not always easy to tell exactly where a specimen was made. The red-figure class, however, is rarely difficult to separate from Greek work. The decoration is much more complex and elaborate, and the reverse is often carelessly executed. (Long after the red-figure style had fallen into disuse in Greece, it lingered on in Italy, particularly in the south.)

Roman Empire. The characteristic and most widely dispersed type of pottery of the Roman Empire was the red, polished Arretine ware, so called because manufacture was at first concentrated at Arretium (modern Arezzo). It is sometimes also misleadingly termed Samian ware, from a supposed connection with the island of Samos. The body was generally formed in a mold and was frequently decorated with raised designs. These were achieved by using a mold that had itself been impressed with several stamps arranged in the desired pattern. This decorative technique—which gave the ware yet another name, terra sigillata (clay impressed with designs)—was borrowed from metalwork. The patterns, too, were often influenced by metalwork and

Figure 120: Etruscan amphora of *bucchero* ware decorated with a frieze of horsemen in relief, 6th century BC. In the British Museum. Height 52.1 cm.
By courtesy of the trustees of the British Museum

include floral and foliate motifs, mythological scenes, and scenes from daily life. The potteries at Arretium, which were organized on factory lines, operated between about 30 BC and AD 30. Their products were highly prized and widely exported.

Lead glazing perhaps originated or was rediscovered (the Assyrians having used it) in Egypt. Certainly it was established in the Near East by the 1st century BC. The glazes were generally stained with copper to yield a greenish colour and were sometimes used over relief decoration which, like the designs on Arretine ware, betrays the influence of metalwork. The technique reached Italy and France by the 1st century AD.

Of the other varieties of Roman pottery, lamps made either in a buff or a dark gray clay are common and usually have an impressed or molded design. A few depicting Christian motifs or gladiatorial combats are prized a little more highly than most specimens, but, generally, they are of little value. Molded terra-cotta plaques with reliefs of mythological and other subjects borrowed from Greece were often used to decorate buildings.

ISLĀMIC

In quality, the Islāmic pottery of Syria, Egypt, Mesopotamia, Persia, Afghanistan, and Anatolia rivals even the wares of the Far East, and its influence on the development of European pottery was more profound than that of any other region except China. The Islāmic potter, in his turn, owes an incalculable debt to the Chinese.

Influence of Islāmic pottery on Europe

Near and Middle Eastern pottery was at its best between the 9th and 13th centuries, and its history is closely linked to the fortunes of the caliphate (the dominion of the temporal and spiritual head of Islām). Each dynasty was surrounded in its capital by a wealthy and beauty-loving court that patronized artists and artisans. When one dynasty fell and another established itself elsewhere, it seems that the finest potters emigrated to the new capital, carrying with them their special, and often secret, skills. At first the principal centres of manufacture were Baghdad, al-Fusṭāṭ (old Cairo), and Samarkand; later they shifted to Raqqah on the Euphrates and to Rāy (Rhagae) and Kāshān, both in northern Iran.

Most of the extant pottery has been excavated and consequently is fragmentary. Little made before the 14th century has survived above ground; and tombs, often rich depositories of undamaged wares in other regions of the world, are fruitless because Muslims did not bury pottery with their dead. Only one or two discoveries of undamaged wares have been made: for example, at Gurgan, Iran, entire specimens were found carefully packed in large earthenware jars. They had probably formed part of the stock of merchants, who buried them and fled before the invading Mongols in 1221. Because of deterioration through burial, much Islāmic pottery (like Roman and Near Eastern glass) is iridescent.

Early Islāmic. *Umayyad.* There is little pottery of merit from the period of the Umayyad caliphate (661–750). At this time the capital was at Damascus, and the chief interest of the pottery lies in its mingled Mediterranean and Middle Eastern derivation; for example, attempts were made to synthesize the formal repetitive style derived from the ancient Babylonian and Assyrian civilizations with naturalistic ornament in the Greco-Roman style. When the 'Abbāsids overthrew the Umayyads and moved the capital to Baghdad, the European influence on ornament waned. Good use continued to be made of Western techniques, however, particularly of lead glazes that had been employed by Greek and Roman potters since the 3rd century BC.

'Abbāsid. An event that had a profound effect on the development of the Middle Eastern pottery was the presentation of a number of T'ang porcelain bowls to the caliph Hārūn ar-Rashīd about AD 800 (see below *China: T'ang dynasty*). Shortly after this, the first fine pottery was produced in Baghdad and elsewhere in the caliphate. Thus, it seems possible that it was through the example of the Chinese that pottery came to be regarded as an artistic medium instead of a purely utilitarian one. This supposition is borne out by the fact that T'ang wares were in great demand and were imported in large quantities after this date: they and early Islāmic imitations, particularly of the dappled T'ang glazes, have been found in various parts of Mesopotamia and as far apart as Egypt and eastern Persia. Unlike their contemporaries in China, however, Islāmic potters aimed primarily at richness of colour and decoration rather than beautiful shapes and textures. Nearly all their pottery is glazed and is painted with elegant, rather stylized motifs. Floral and foliate ornaments predominate, although complex geometrical patterns are also characteristic. In theory there was a religious ban, formulated in the Ḥadīth (traditions of the Prophet), on all representations of animal life, which were thought to encourage idolatry. In practice, particularly in Persia, the limitation was often disregarded except in the decoration of mosques. The animal figures on pottery are spirited and rhythmical, while the human ones tend to be stiff, resembling those in contemporary miniatures. Arabic calligraphy was commonly and effectively used as an element of design.

Islāmic technical innovations

The Islāmic potters were responsible for a number of important technical innovations, the most influential of which was the rediscovery of tin glaze in the 9th century AD. Though tin was first used by the Assyrians and according to some authorities was discovered as early as 1100 BC, it had fallen into disuse. The 'Abbāsid potters first used it in an attempt to imitate the texture of T'ang wares, but soon it became the vehicle for characteristically Middle Eastern decoration. From Mesopotamia and Persia the technique was later taken to Moorish Spain and then to Italy and other parts of Europe, where it was employed for a number of important wares—maiolica, faience, and delft (see below *European: to the end of the 18th century*).

Like that of tin glazing, the technique of lustre painting was perfected (and probably invented) by Islāmic potters. Again, like tin-glazing, it later passed to Muslim Spain but not to the Far East. Lustre on pottery probably was first used to cover entire vessels, thus simulating vessels made of precious metals that were proscribed by sumptuary laws laid down in the Ḥadīth, which sought to preserve the earlier simplicity of Muslim life. The metallic pigments employed in lustre painting were probably silver and copper in combination, although an occasional ruby glint

suggests that gold may sometimes have been included. After firing, the painting may be dull yellow, golden brown, or olive, tinged with green or red.

Extensive use was made of slip. Wares such as the early Gabrī type of the 11th century and later have a reddish body washed over with white slip. Designs were executed by scratching through the slip to the body beneath (sgraffito). On some later specimens the background was cut away to leave a raised design in white slip or the design was incised through the white slip and then was itself covered with green and brown glazes. The usual motifs are large floral forms, animals, and bold inscriptions. Sgraffito ware became common throughout the Middle East and appears in Egypt and Syria in the 13th century.

Many fragments of Chinese pottery and porcelain have been found at the site of Sāmarrā', on the Tigris, where the 'Abbāsids built their summer palaces in the 9th century (see below *China: T'ang dynasty*). Among the native wares are some made in a buff body decorated in relief under a green glaze; others with monochrome green, white, and yellow glazes or with glazes in imitation of a well-known type of T'ang decoration; and those painted with cobalt blue (perhaps the earliest use of underglaze blue) and further embellished with lustre of various colours.

Sāmānid. To the northeast, beyond the Oxus (modern Amu Darya) River, the Sāmānid dynasty (874–999) became practically independent of the caliphate at Baghdad and fostered a national artistic and literary revival. Sāmānid pottery, which has been found chiefly at Samarkand and Nīshāpūr, differs from the pottery of more westerly regions in technique and style. The best pieces have a reddish body covered with a white, vivid red-brown, or purplish-black slip that was then painted and fired under a lead glaze. The function of the slip, besides providing colour, was to prevent the pigments of the painting from running when the lead glaze was applied. The colours used in painting were the same as those of the slips, with the addition of yellowish green and browns. The designs often consist of the angular Arabic Kūfic characters or stylized birds and floral motifs. The shapes are plain—usually either plates or rather shallow bowls—and the total effect is both bold and elegant.

Egyptian. Egyptian pottery of the Islāmic period was at its best during the Fāṭimid dynasty (969–1171). Wares were at first coarser than those of Mesopotamia because of the poor quality of local materials, and the shapes were less refined, since Chinese influence was absent. Lustre painting (probably introduced in mid-10th century) was nevertheless, excellent in quality. A typical feature is the painting on the backs of dishes, a practice derived from Baghdad and later copied by the Moorish potters of Spain. Signed specimens of lustre ware and tin-glazed wares are known, the best coming from a potter named Sa'd.

Painting on the backs of dishes

Toward the end of the period a much whiter type of ware, with a compact body, came into use and thereafter became common throughout the Middle East. Another widespread group of wares, popular until the 14th century, has decoration carved and incised into the body and is covered with transparent glazes. The patterns suggest the influence of some of the Sung wares of China.

Mesopotamia and Persia. *11th to 15th century.* In the 11th century the Seljuq Turks overran Persia and Mesopotamia, and their ascendancy lasted until the advent of the Mongols during the 13th century. As the Seljuqs had no capital, the most flourishing cities during this time were those on the trade routes. In the 12th century very fine pottery was made in the new white body recently developed in Egypt; it was decorated with bold carving, occasional piercing, and translucent glaze. Most of these wares are said to have been found at Rāy near Teheran, where many other beautiful wares have been excavated. Wares with a sandy body and a clear glaze were painted with a golden-brown lustre, often in conjunction with blue. These seem not to have been made after the city was sacked by Genghis Khan in 1220. Especially associated with Rāy are examples of *minai* painting of uncommon quality. The *minai* technique, a Persian discovery of the 12th century, was a method of decoration in which colours were painted onto a glazed and fired bowl and then fixed by refiring the bowl at a comparatively low temperature. The advantage of the process was that many colours that would not have withstood the heat of the first firing could now be used. The technique may perhaps have influenced the rare examples of overglaze decoration on late Sung or Yüan wares from Tz'u-chou, although it did not come into common use in China until the early part of the 15th century (see below *China: Ming dynasty*).

At Rāy the glaze is cream or turquoise, and the *minai* palette included blue, turquoise, purple, red, green, and white, with the addition of gold leaf. All these colours, except the blue, are mat in appearance, and the style strongly recalls that of Persian manuscript illumination of the 13th century.

Another technique employed at Rāy was the use of silhouette decoration, a kind of sgraffito. The pot was covered with a thick black or blue and black slip, and the design was carved out with a knife. The glazes were applied without colour or stained with copper to yield a brilliant turquoise (Figure 121).

Figure 121: Persian tankard with decoration cut through a black slip and covered with a turquoise glaze, 12th century, found at Soltānābād (modern Arāk, Iran). In the Victoria and Albert Museum. Height 12.7 cm.

Raqqah was a prosperous trading city until it was sacked by the Mongols in 1259. Most of its pottery, which can be dated between the 9th and 14th centuries, is rougher and the designs bolder than those of Rāy. The body is white, inclining to buff, and is covered with a siliceous glaze. Some of the Raqqah fragments are painted with a brownish lustre. Others have designs in relief, sometimes covered with an opaque turquoise glaze or with a bluish-green translucent glaze. In the 12th and early 13th centuries bold designs were executed in black under pale-blue glazes and, more frequently, in blue and black under a clear glaze. Occasionally the glazes were stained purple with manganese.

Kāshān tiles

Kāshān is chiefly famous for its tiles, in fact the words *kāshī* or *kāshānī* ("of Kashan"), are commonly used as synonyms for tile (and have been incorrectly applied to tilework from India). Lustre-painted tiles had been made since at least the 9th century and were used mostly on the walls of mosques and public buildings. Those of Kāshān, particularly in the 13th and 14th centuries, are distinguished by their fine workmanship, brilliance, and intricacy of design. In shape they are square, rectangular, or of interlocking cross or star shapes, each carrying a small part of the total design. The relief inscriptions are frequently picked out with blue pigment.

Also associated with Kāshān are the *lakabi* ("painted") wares made in the 12th century. The term, a misnomer, refers to a variation of the sgraffito silhouette technique mentioned above: an incised design was decorated with different coloured glazes (blue, yellow, purple, and green), which were kept apart by intervening threads of clay. Although a number of *lakabi* wares were also made at Raqqah, the technique was soon abandoned at both places, as the glazes always tended to run out of their compartments during firing, giving a smudged effect.

Both the original site of Solṭānābād and the nature of the wares that may have been made there are extremely uncertain. Principally associated with it are wares decorated with relief molding under a turquoise or dark-blue glaze or painted in black slip under a clear turquoise glaze. They date from the second half of the 13th century onward. Toward the end of the 12th century the glaze material was frequently mixed with the white-burning clay then in use. In the more highly fired specimens the product is not unlike a primitive soft porcelain, and occasional specimens are slightly translucent. These wares probably inspired the attempts to make porcelain at Florence (see below *European pottery to the end of the 18th century*). Neither stoneware nor true porcelain was ever made in Persia.

After the Mongol conquests of the 13th century the production of pottery practically ceased, except at Kāshān. A slow revival began about 1295, and, although pottery in the Near and Middle East never again reached its former height, some fine wares were made at Solṭānābād in the 14th century. Good use was made of the rich sombre colours beloved by the Mongols, particularly dark blues, grays, and blacks.

Later Persian. Since the whole of Central Asia now lay under the Mongol domination, overland trade with China greatly increased. By the 15th century Chinese influence, particularly that of Ming blue-and-white, was predominant, and the older styles were tending to die out (see below *China: Ming dynasty*). A group of blue-and-white wares belonging to the 15th and early 16th century are known as Kubachi wares because large numbers of them survived above ground in this town in the Caucasus. They have a very soft body, a brilliant crackled glaze, and rhythmical and spontaneous designs. The later Kubachi blue-and-white is closer to the Chinese originals.

Polychrome appears about 1550, and the palette includes a red related to, though lighter than, the Armenian bole introduced about the same time in Turkey (see below *Turkish pottery*). The best polychrome painting was done on tiles. Tabriz has been suggested as the real centre of manufacture, but although it seems likely that Tabriz was a manufacturing town in view of its tiled mosques and the fact that Tabriz potters were famous abroad (and indeed were either invited or carried off to Turkey on two occasions), no kiln sites have been found there.

One of the later kiln sites in Persia is Kerman, which was the leading pottery centre in the 17th century. Its wares are characterized by a very strong bright blue and a wavy, rather bubbly, glaze. Pseudo-Chinese marks were frequently added to the blue and white. The most usual colours on Kerman polychrome wares are blue, green, browns, and a bright red similar to Armenian bole. The quality of production declined considerably during the 18th century.

Lustre painting

Lustre painting, which had almost ceased in the 13th century, was revived during the second half of the 17th century and perhaps lasted into the 18th century. Its place of manufacture is not known. Most of the objects decorated in this manner are small bottles or spittoons, and their cramped designs are timid and fussy. The lustre is warm brown, often with a strong red tinge, and was sometimes used in conjunction with blue glaze. Another early technique revived at the same time was piercing, formerly practiced in the Seljuq era. There are a number of delicate pierced white wares covered with a colourless glaze, which were imitated in China during the reign of Ch'ien-lung. Pierced pottery and porcelain of this kind was often known in Europe as Gombroon ware, the name of the port (now Bandar 'Abbās) from whence it was shipped.

Chinese celadon was imitated, not very successfully, from the 14th century. In the 16th century other monochrome glazes were produced at Kerman and elsewhere. These and the celadon were frequently decorated with painted or incised ornament—the former a practice quite foreign to Chinese Sung dynasty wares.

During the 18th century most of the pottery produced in Persia was inferior blue-and-white. In the 19th century the standard declined still further with the adoption of the Chinese-inspired *famille rose* palette (see below *China: Ch'ing dynasty*), and only a group of wares made at Teheran between 1860 and 1890 can command any respect. Some excellent peasant pottery with a buff body and lead glaze was made in Turkistan, however.

Syrian. The potters from al-Fusṭāṭ and Raqqah may have migrated to Damascus after their potteries were destroyed by the Mongols, for lustre painting continued in Syria throughout the 13th and 14th centuries after it had ceased elsewhere in the Middle East. The lustre ranges in colour from silver to yellow and dull brown and is often used in conjunction with a blue glaze on big, heavy jars and albarellos (a jar with an incurving waist, used for dry drugs and ointments). Characteristic are gold designs arranged in panels with much use of inscriptions and heraldic devices. The body material is coarse and grayish, and the glaze sometimes has a wide crackle. Lustre painting fell into disuse in Syria about 1400 and might have died out altogether had not the secret meantime been carried from Egypt to Spain (see below *European pottery to the end of the 18th century*). The commonest type of Syrian pottery in the 14th century is a blue-and-black style similar in shape and design to the lustre ware. Rather uncertainly drawn animals appear on some of the vessels.

The earliest known Middle Eastern copies of Chinese blue-and-white were made in Syria at the end of the 14th century. Blue-and-white became commoner on both vessels and tiles in the first half of the next century. Later, the potteries seem to have fallen into disuse until the new mosque built in Damascus by the Turkish ruler Süleyman I (the Magnificent) in the mid-16th century provided a fresh impetus for the industry. The polychrome tiles of the 16th century at first have designs with a hard black outline; later, a more flowing foliate style was developed. A soft purple replaces the Armenian bole of Iznik (see below *Turkish pottery*). Vessels and tiles, gradually declining in quality, continued to be made in Damascus until the end of the 18th century.

Turkish. A branch of the Seljuq Turks occupied Anatolia from 1078 to 1300 and was succeeded by the Ottoman Turks, who first extended their lands westward, conquering Byzantium in 1453 and in the 16th century becoming masters of much of southeastern Europe and the lands lying to the east and south of the Mediterranean. The first notable pottery wares from Turkish lands were the tiles and bricks covered with coloured glazes made in Anatolia for architectural purposes in the 13th century. Mosques in particular were decorated in this way. (Persian influence in decoration suggests the presence of potters from that region.) The art of tilework apparently died out after 1300 and was not reintroduced until about 1415, when Persian craftsmen were brought from Tabriz to decorate the mosques at Bursa and Edirne. Apart from tilework, pottery appears to have received little encouragement until the late 15th century, by which time the chief centre of production was firmly established at İznik (earlier called Nicaea).

The great era of Turkish pottery

The great era of Turkish pottery (*c.* 1500–*c.* 1580) coincides with the expansion of Ottoman power. Decoration was at first influenced by 15th-century Ming blue-and-white porcelain. The earlier designs were probably taken at second hand from Persian sources, since a distinctly Persian flavour is usually evident. This is indicated by the intricacy of the designs and their arrangement in bands, and by the shapes of some of the vessels, which suggest the influence of metalwork. At one time the wares in this style, which lasted until about 1525, were thought to come from Kütahya in central Anatolia and are still sometimes known by that name.

At this and later periods the body of Iznik pottery was soft and sandy. It was made from grayish-white clay covered with a thin slip that was usually white, although occasionally red or blue was used as a ground on later wares. Decoration was carried out in underglaze colours under a transparent siliceous glaze. The commonest shapes are flat dishes, but jugs, dishes with a high foot, and bowls are also found. Cylindrical vessels with small rectangular handles set halfway down are flower vases, not tankards, as one might think. A rare form is a pottery version of a mosque lamp.

During the next period (*c.* 1525–50), some wares of which

have been erroneously attributed to Damascus, Iznik pottery was at its finest. Ming blue-and-white was now copied directly; for example, the central motif of grapes on a dish in the Victoria and Albert Museum, London, is an almost exact imitation of a well-known mid-15th century Chinese motif. On the same dish is a characteristic border pattern, which was called the Ammonite scroll border because it was thought to resemble the coiled shell of the fossil ammonite but which is certainly a debased version of the Ming Rock of Ages pattern. This scroll border appears often; a slightly later and even more debased version, which incorporates large S-shaped scrolls, is sometimes known as the dollar pattern.

The palette was gradually expanded to include turquoise, sage green, olive green, purple, and black. Most of the blue and turquoise specimens are painted with flowers. The Chinese flora motifs were almost entirely replaced by tulips, poppies, carnations, roses, and hyacinths in the form of fairly symmetrical sprays springing from a single point. The earliest flowers are often rather more stylized than the later, perhaps because the representation of living things was prohibited by Qur'ānic (Koranic) tradition. Even on comparatively late examples, floral designs are sometimes stylized to the point of abstraction, suggesting that decorators might have suited their patterns to the religious susceptibilities of their customers. An effective abstract pattern is formed from a series of overlapping scales that are usually carefully drawn (Figure 122). The

Scale pattern

same ground was later employed in Italy on maiolica and at the Berlin porcelain factory and may have indirectly inspired the series of wares with scale grounds made at Worcester, England.

After about 1550 Iznik pottery enters its third stage. The most notable technical innovation is the use of Armenian bole (sealing-wax red), a thick pigment that stands out in slight relief from the surface of the vessel.

The other great change is that tiles, which had previously been made in small numbers, became all important and remained so until the early 17th century. They were used to provide lavish decoration for the new mosques built at Constantinople by Süleyman I. Once again potters were brought from Tabriz to begin the work. Much use is made of copper green and the new red, the colours very brilliant on the glossy white ground. The tiles, usually square, make up flowing repeating patterns or long high pictures with elaborate borders.

On pottery, symmetrical sprays of flowers continued to be used as decoration until about 1600. Paintings of animals and birds are found occasionally, probably executed by Persian workmen since their resemblance to Persian wares is strong. The rare specimens with human figures were probably painted by Greeks or Armenians for export to the West. Turkish sailing vessels sometimes appear as a decorative motif.

In the 17th century the quality of Iznik wares declined, and by 1800 manufacture had ceased. At Kütahya, pottery making had begun by 1608 and continued into the middle of the 20th century. The wares, though inferior, have some resemblance to those of Iznik with the addition of a yellow pigment.

EUROPEAN: TO THE END OF THE 18TH CENTURY

European wares made before the 19th century fall into six main categories: lead-glazed earthenware, tin-glazed earthenware, stoneware, soft porcelain, hard porcelain, and bone china.

Lead-glazed earthenware was made from medieval times onward and owes little to outside influences. The body is generally reddish buff in colour; the glazes are yellow, brown, purplish, or green. The wares are usually vigorous in form but often crudely finished. Lead-glazed wares fell out of favour when tin glaze became widely known toward the end of the 15th century, but they returned to popularity with the advent of Wedgwood's creamware shortly after the middle of the 18th century. The body of this later lead-glazed earthenware is drab white or cream, the glaze clear and transparent like glass, and the forms precise.

The first important tin-glazed wares came from Italy during the Renaissance, and these colourful examples of the painter's art exerted a profound influence on later work elsewhere. Manufacture spread rapidly, first to France, then to Germany, Holland, England, and Scandinavia. Under the name of maiolica, faience, or delft, it enjoyed immense popularity until the advent of Wedgwood's creamware, after which the fashion for tin-glazed ware declined rapidly.

Stoneware is first commonly seen in Germany during the 16th century; its manufacture was developed in England during the 18th century, culminating in the unglazed ornamental jaspers and basaltes of Wedgwood.

Two other types of ware, less common than those already discussed, are slipware and lustreware. Slip was applied both as a covering over an earthenware body and in the form of decoration, for example on the sgraffito wares of Italy (which owe a good deal to similar wares from Byzantium) and the dotted and trailed slips of 17th- and 18th-century England. Lustre pigments were used in Spain, where they are the principal decoration on the magnificent series of wares referred to as Hispano-Moresque; in Italy, where they supplement other modes of decoration; and much later, in England—although in the last case they are no longer artistically important.

Porcelain and bone china

The manufacture of soft porcelain was essayed in 16th-century Italy under the patronage of Francesco de' Medici, grand duke of Tuscany. Similar attempts were made elsewhere in Italy about the same time, and manufacture is supposed to have been continued at Pisa and at Candiana, near Padua (Padova). The first production of soft porcelain on a considerable scale did not take place, however, until toward the end of the 17th century in France.

In Saxony about 1675 Ehrenfried Walter von Tschirnhaus started experiments to make porcelain from clay mixed with fusible rock. Almost certainly he had made hard porcelain by the end of the century, but manufacture did not become a practical commercial proposition until the year of his death, in 1708. Experiments were continued by his assistant, an alchemist named Johann Friedrich Böttger, who is sometimes credited with von Tschirnhaus' discovery. The factory was established at Meissen about 1710, and the first porcelain sales of any consequence took place at the Leipzig Fair in 1713.

Later, at the end of the 18th century, Josiah Spode the Second added bone ash to the hard porcelain formula to make bone china.

Byzantium. In AD 330 Byzantium became the imperial

capital of the Roman Empire and was renamed Constantinople. The term Byzantine, however, is applied to the period that ended in 1453, when Constantinople was captured by the Ottoman Turks (and renamed Istanbul).

Since it was not a Christian custom to bury pottery with the dead, few wares survive, and chronology is difficult. Most of the surviving wares fall into two classes: one is a red-bodied type, sometimes with stamped relief decoration under a clear glaze; the other, a sgraffito type with human figures, animals, birds, monograms, foliate designs, the Greek cross, and the like, engraved through a white slip and covered with yellow and green glazes. The latter is the commonest type after the 12th century. Both styles were fairly widespread and have been recovered in fragmentary form from excavations at Istanbul, and in Greece, Cyprus, and the Crimea.

Spain. The earthenware of Spain falls into two classes: lustreware and painted tin glazed ware.

Lustreware. The lustre technique spread to Moorish Spain by way of Egypt, but it is impossible to say exactly when it arrived.

Hispano-Moresque pottery

The body of Hispano-Moresque pottery is usually of fairly coarse clay, which has burned to a pinkish buff, covered with a tin glaze containing lead in varying proportions. The lustre, added overglaze, varies in colour from golden to a pale straw, and a coppery lustre almost invariably indicates at least a 17th century date. Many dishes were additionally painted in blue and, less often, with manganese.

Most surviving wares of the early period are dishes of various shapes. Less common are albarellos, waisted drug jars based on a Middle Eastern form (Figure 123). Vases based on the old Iberian Amphora but with two massive wing handles (the Alhambra type) are very rare. The decoration on wares of this early period is predominantly Moorish. Fine specimens of this kind are unlikely to be later than 1525. Subsequently, Spanish artists repeated the Moorish designs, but these often degenerate in their hands; and Arabic and the Kufic script, frequently used by Moorish potters, becomes meaningless. The early designs are, for the most part, plant forms and arabesques, both the vine leaf and the bryony leaf being used. A little later there are magnificently drawn animals in heraldic form, principally lions and eagles. Still later there are deer and antelope, which may owe something to Persian sources.

By courtesy of the trustees of the British Museum

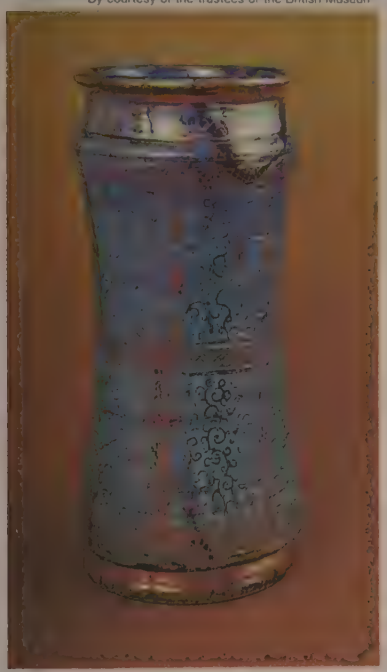

Figure 123: Hispano-Moresque albarello painted with lustre on a blue ground, Valencia, *c.* 1460. In the British Museum. Height 27.6 cm.

Dishes with coats of arms of noble families surrounded by vine- and bryony-leaf ornament are unusually fine. Many of them were made in Valencia and the neighbouring village of Manises for Italian families. A feature of many of the dishes is the lustre decoration on the reverse. Although often no more than a series of concentric circles, occasionally there are superb eagles and other animals found on dishes from Valencia that are even finer than the obverse designs.

In the 17th century much lustred pottery was made for the cheaper markets and for export to England. The painting is executed in a lustre pigment of deep coppery hue. While this ware is not important in comparison with the early wares, it is often decorative.

Other tin-glazed ware. Although the influence of Valencian lustre pottery on later Italian maiolica is obvious, the wares of Paterna, near Valencia, were hardly less influential in the 14th century. They were decorated in green and manganese, often with motifs taken from Moorish sources; this combination of colours is to be seen in early Italian pottery from Orvieto and elsewhere.

Much tin-glazed pottery of excellent quality was made at Talavera de la Reina, in New Castile, during the 17th and 18th centuries. The palette is characteristic of much Spanish tin-glazed ware; green and manganese play a distinctive part, frequently combined with touches of orange-red and gray. The *istoriato* style of Urbino (see below *Italy*) was copied here, and the Italian painter and engraver Antonio Tempesta (1555–1630) provided a source of inspiration for some of the painting. Alcora, in Valencia, made much faience of excellent quality during the 18th century.

Kinds of tilework

Tilework was particularly common in Spain from the earliest period; according to one proverb, only a really poor man had "a house without tiles." At first tilework was made with a typically Persian technique by which thin slabs of tin-glazed pottery were sawn into pieces and embedded in a kind of mortar (tile mosaic). The *cuerda seca* method of making tiles followed about 1500: outlines were drawn on the surface in manganese mixed with a greasy substance that prevented the coloured glazes used from mingling. Tiles made by the *cuenca* technique had deeply impressed patterns the compartments thus formed being filled with coloured glazes. Tiles were also decorated with lustre pigments.

Porcelain. The early porcelain made at Buen Retiro, near Madrid, in the 1760s, had been justly compared to that of Saint-Cloud. The quality of the ware was good, and some skillful figure modelling was done by Giuseppe Gricci, who had previously worked at Capodimonte (see below *Italy*).

Italy. The pottery of Italy is extremely important not only in itself but for its subsequent influence in other European countries. Indeed, its influence may have spread even farther afield: a few specimens of Ming porcelain have motifs that may have been inspired by it.

There are two well-defined classes of Italian earthenware: maiolica, or tin-glazed ware, and pottery decorated in the sgraffito technique.

Maiolica. Tin-glazing was introduced in the 13th century from the Middle East through the Muslim civilization in southern Spain, wares being shipped from there to Italy by Majorcan traders. The term maiolica was at first applied to this Hispano-Moresque lustreware, but in the 16th century it came to denote all tin-glazed ware.

Italian maiolica is principally noteworthy for its painted decoration, which excelled in technical competence anything produced in Europe since classical times. The painting was executed in several colours on the dry but unfired tin glaze. Great skill was needed, since the surface absorbed the colour as blotting paper absorbs ink, and erasures were therefore impossible. The best wares were given a final coating of clear lead glaze called *coperta*. The range of colours was comparatively limited: cobalt blue, copper green, manganese purple, antimony yellow, and iron red formed the basic palette, while white was provided by the tin-glaze material. When white was used for painting, it was applied onto a bluish-white glaze (*bianco sopra bianco*, or "white on white"), or on a light-blue (*berettino*), or dark-blue ground.

Lustre pigments

Lustre pigments were introduced from Spain. The lustre of Italian wares is often the golden-yellow colour derived from silver, and sometimes it is ruby, suggesting the use of gold. The silver lustre often developed a nacreous effect known as mother-of-pearl (*madre perle*).

The forms of maiolica are few and fairly simple. Generally, they were dictated by the need for a surface on which the painter could exercise his skill; thus, dishes form the greater part of surviving wares. It is doubtful whether most maiolica was ever intended for general use. Dishes were displayed on sideboards and buffets more often than they were placed on the table. Gaily coloured drug jars were a fashionable decoration for pharmacies and include the albarello shape, copied from Spain, for dry drugs, and a spouted jar for wet drugs. Ewers (pitchers) with a trefoil (leafshaped) spout, derived from the Greek oenochoe, were made, as well as the massive jars representative of Florentine work of the 15th century.

The earliest maiolica, beginning in the 13th century, is decorated in green and manganese purple in imitation of the Spanish Paterna ware. Much work of this kind was done at Orvieto, in Umbria, where the characteristic form was a jug with a disproportionately large pouring lip. Orvieto ware has almost become a generic term for anything in this style, although similar vessels were made at Florence, Siena, and elsewhere. It was current in the 14th century and continued in the 15th century, when other colours were added to the palette. The decorative motifs—masks, animals, and foliage—are Gothic, with some traces of Eastern influence.

From Florence came a series of wares painted in a dark, inky, impasto (or very thick) blue. These, too, have Gothic ornament, particularly oak leaves, which came into use sometime before 1450. Heraldic animals also appear on some specimens. This kind of decoration was obviously inspired by Spanish pottery, and a few examples are hardly more than copies. Soon after 1500, Florentine production was concentrated in the castle of Caffagiolo, in Tuscany, and came under the patronage of the Medici family, whose arms appear frequently. A notable addition to the palette here was a bright red pigment, a most difficult colour to attain and one not often used.

Istoriato style

Gothic ornament was gradually displaced by classical motifs, such as grotesques, trophies, and the like, which, early in the 16th century, themselves gave way to the *istoriato* style. This style, no doubt inspired by the achievements of contemporary painting, imitates the easel picture closely. Its realism, including the use of perspective, is quite unlike any previous ceramic decoration. The subjects were often classical, but biblical subjects, some taken from the woodcuts of Bernard Salomon (*c.* 1506–61), are frequently represented. Maiolica was often called Raffaelle ware, a tribute to the influence of the painter Raphael (1483–1520), although he, in fact, never made any designs for pottery. In particular the maiolica painters copied his *grotteschi* (grotesques), motifs adapted from those rediscovered in the grottoes of the Golden House of Nero soon after 1500 and so-called in consequence. They are usually fantastic combinations of human, animal, and plant forms. The works of Albrecht Dürer and Andrea Mantegna were also borrowed, often through engravings made by Jacopo Ripanda (Jacopa da Bologna and Marcantonio Raimondi); some examples are almost exact copies, others are freer interpretations. The paintings sometimes occupy the centre of the dish with a border of formal ornament surrounding them, but in many instances, notably those from Urbino, they cover the entire surface. It is often impossible to regard the pottery body as anything more than a support for the painting, its pictorial or narrative subject having been executed with little or no consideration for the nature of the object it decorated. Although pottery decoration is rarely successful unless it is designed to enhance, or at least not to detract from, the shape of the body, an exception must be made for some of these colourful wares: at their best they are highly ornamental.

The *istoriato* style (Figure 124) probably developed at Faenza (Emilia) in about 1500. One of the earliest and most important centres of production, it had been manufacturing maiolica since before 1450. Almost as early are some examples from Caffagiolo. Castel Durante adopted the same style, and it is particularly associated with the name of Nicola Pellipario (died *c.* 1542), the greatest of the maiolica painters. He also painted grotesques similar to those of Deruta, in Umbria, which are rather more stylized than the grotesques introduced later in the 16th century at Urbino that are humourous and full of movement. The former are often used as a surround to an interior medallion in the *istoriato* style. Urbino was probably the largest centre for the manufacture of maiolica at the time. The industry there was under the patronage of the Della Rovere family, whose name, meaning "oak tree," led to the adoption of the oak-leaf motif in wreathed form.

The Deruta factory

Among the early factories, that of Deruta (wich may have been under the patronage of Cesare Borgia) is of considerable importance. Maiolica has been made there from medieval times, and manufacture continues in the mid-20th century. Deruta potters about 1500 were the first to use lustre pigment, which was of a pale-yellow tone,

Figure 124: "Death of the Virgin," maiolica plaque painted in the *istoriato* style by an unknown Italian artist often referred to as the Master of the Death of the Virgin, Faenza, Italy, *c.* 1510. The composition is taken from Martin Schongauer's engraving of the same subject. In the British Museum. Diameter 26.7 cm.

and they also adopted the Spanish practice of painting designs on the reverse of dishes. They also often covered only the obverse with tin glaze and applied a lead glaze to the reverse—again, a typically Spanish practice. The best work was done before 1540.

The use of lustre pigments at Gubbio, in Umbria, probably started soon after it began at Deruta. The quality of the work was such that maiolica was sent from Castel Durante, Faenza, and even from Deruta itself for this additional embellishment. An interesting series of dishes is that painted with the portraits of young women, often with the addition of a terse and appreciative comment such as "*Bella,*" which were made at Deruta, and also apparently at Gubbio.

Maiolica was manufactured in Venice between the 16th and 18th centuries. As might be expected in an important seaport with worldwide trade, its maiolica often shows Eastern influence. The designs of Iznik were sometimes copied (as they were, in fact, on other Italian wares of the period), and imitations of Chinese porcelain of the Ming period gave rise to a style known as *alla porcellana* ("in the manner of porcelain").

Of the later potteries, that of Castelli, near Naples, did excellent work from the 16th century onward, although its later wares tend to become pedestrian. *Istoriato* painting was revived there in the 17th century in a palette paler in tone than that of early work in this style. Much maiolica survives from Savona, in Liguria, a good deal of which is painted in blue in Oriental styles.

Although hardly to be classified as pottery, sculptured reliefs were made by Luca della Robbia (died 1482) in terra cotta and covered with maiolica glazes. He was followed by his nephew, Andrea, and the latter's sons. Giorgio Vasari's suggestion that Luca invented the maiolica glaze is erroneous.

Sgraffito wares. Sgraffito wares are comparatively rare. The technique was derived from Byzantine sources by way of Cyprus which was under Venetian rule from 1472 to 1570. Manufacture was confined to northern Italy, the largest centre being at Bologna. The body of the sgraffito ware was covered with a slip of contrasting colour, the decoration then being scratched through to the body beneath and the whole covered with a lead glaze, which has a yellowish tone. Often the incised designs were first embellished with underglaze colours (blue, green, purple, brown, and yellow) that tended to run during firing. This technique died out finally at the end of the 18th century, but some important work of the kind was done in the late 15th and 16th centuries.

Porcelain. There are only about 50 surviving pieces of the soft-paste porcelain made in Florence at the time of the Medicis, and little is known of its actual production. The earliest definite date for manufacture is 1581. Painting is nearly always in blue with manganese outlines. Most decorative motifs are derived from China, Persia, or Turkey, and the forms usually copy those of Urbino maiolica.

No hard porcelain was made in Italy until Francesco and Giuseppe Vezzi's factory was established in Venice in 1720. It made fine hard porcelain the body of which has a slightly smoky colour. The style is Baroque, and the palette is notable for a brownish red. Another factory, that of Geminiano Cozzi, started in 1764, was the one where most Venetian porcelain was made. Cozzi worked in the Meissen and Sèvres styles and produced some good figures.

Ginori and Capodimonte

The porcelain factory at Doccia, near Florence, was founded by Marchese Carlo Ginori in 1735. Coffeepots in the Baroque style, sometimes painted with coats of arms, are characteristic of the early period. Equally fine figures were made during the 18th century. Porcelain with figure subjects in low relief was made only at Doccia, although it has been repeatedly and erroneously attributed to the soft-porcelain factory established in the royal palace of Capodimonte by Charles III of Naples in 1743. As well as extremely well painted service ware, Capodimonte is renowned for its figures. The factory was transferred to Buen Retiro, near Madrid, in 1759, when Charles became king of Spain (see above *Spain*).

France and Belgium. The medieval pottery of France is difficult to date and classify with accuracy, but lead glaze was in common use by the 13th century at the latest. Proficient sgraffito decoration was done at Beauvaisis (Oise) and at La Chapelle-aux-Pots (Charente-Inferieure).

Palissy rustic ware

Lead-glazed wares of the 16th century. Bernard Palissy began to experiment with coloured glazes about 1539 and, after much difficulty, succeeded in producing his rustic wares in 1548. For the most part these are large dishes made with wavy centres intended to represent a stream, with realistically modelled lizards, snakes, and insects such as dragonflies grouped thereon. They are decorated on the obverse with blue, green, manganese purple, and brown glazes of excellent quality, while the back is covered with a glaze mottled in brown, blue, and purple. Palissy later turned his attention to classical and biblical subjects, which he molded in relief. After his death in 1589, work in his style was continued at the Avon pottery, near Fontainebleau.

Almost contemporary with Palissy's rustic ware is a type of pottery made in the style of the metalwork of the period. It was made at Saint-Porchaire and is sometimes called, erroneously, *Henri Deux* ware, or *faience d'Oiron.* The body is ivory white and covered with a thin glaze. Before firing, designs were impressed into the clay with metal stamps like those used by bookbinders, and the impressions were then filled with slips of contrasting colours. This technique resembles the *mishima* technique of decoration in Korea (see below *Korea*).

Faience, or tin-glazed ware. The technique and the designs of Italian maiolica influenced the development, in the early 16th century, of French faience. There were Italian potters at Lyon in 1512, and, by the end of the 16th century, painting in the manner of Urbino was well established there. Faience was also made at Rouen, probably as early as 1526, and at Nevers toward the end of the 16th century.

A new factory, established at Rouen about 1656 by Edme Poterat, introduced a decoration of *lambrequins,* ornament with a jagged or scalloped outline based on drapery, scrollwork, lacework ornament, and the like. *Lambrequins* were extremely popular and were copied at other porcelain and faience factories. The faience of Nevers, too, is extremely important and shows the Baroque style at its best. In the second half of the 17th century the porcelain of both China and Japan became increasingly well known in Europe, and many designs were borrowed from Chinese sources by potters at Nevers and elsewhere.

The factory of Moustiers in the Basses-Alpes was founded by Pierre Clérissy in 1679. During the early period frequent use was made of the engravings of Antonio Tempesta (1555–1630) as well as biblical scenes. Later came a series of dishes decorated with designs after Jean I Bérain (1637–1711), whose work greatly influenced French decorative art at the time. These designs usually include grotesques, baldacchini (canopies), vases of flowers, and the like, linked together by strapwork in a typically Baroque manner.

In 1709, when Louis XIV and his court melted down their silver to help pay for the War of the Spanish Succession, the nobility looked for a less expensive medium to replace it. In consequence, faience gained in popularity and importance. A great deal was manufactured in the region of Marseilles, the factory of the Veuve Perrin being particularly noted for overglaze painting in the Rococo style. Perhaps the most influential factory was that of Strasbourg, in Alsace (which had officially become part of France in 1697), founded by C.F. Hannong in 1709. The wares—painted in blue, in other faience colours, and in overglaze colours—were much copied elsewhere. Overglaze colours were introduced about 1740, their first recorded use in France. (For the first use in Europe, see below *Germany and Austria.*) Brilliant *indianische Blumen* (flower motifs that were really Japanese in origin but that were thought to be Indian because the decorated porcelain was imported by the East India companies) were painted in a palette that included a carmine similar to the Chinese overglaze rose ("purple of Cassius"). A characteristic copper green was also used. *Deutsche Blumen* ("German flowers") were introduced, perhaps by A.F. von Löwenfinck, about 1750, and inspired similar painting elsewhere. Figures by J.W. Lanz, who also worked in porcelain here and at Frankenthal, are to be seen. Much work was done in the fashionable Rococo style, including objects, such as clock cases and wall cisterns, and tureens in the form of fruit and vegetables. Both faience and porcelain in a variety of decorative forms were used for the banqueting table. Such table decoration, which in the 17th century had been supplied by confectioners who worked in sugar, had become very fashionable in Europe.

Faience and porcelain as table decoration

The wares of Niderviller, in Lorraine, were much influenced by those of Strasbourg. The later figures were probably modelled by the sculptor Charles Gabriel Sauvage, called Lemire (1741–1827), and some were sometimes taken from models by Paul-Louis Cyfflé (1724–1806). At Lunéville, not far away, Cyfflé worked in a pleasant but sentimental vein and used a semiporcelain biscuit body known as *terre-de-Lorraine,* which was intended to resemble the biscuit porcelain of Sèvres. The work of both Sauvage and Cyfflé is extremely skillful.

Faience was made at Tournai (now in Belgium) and at Brussels during the 17th century. Their styles were mainly derivative, but Brussels made some excellent tureens in forms such as poultry, vegetables, and fruits during the Rococo period.

After 1800 most French pottery factories concentrated on the manufacture of *faience fine* (creamware).

Porcelain. In the second half of the 17th century much interest was taken in both faience and porcelain, although the technique of making soft-paste porcelain (*pâté tendre*) had yet to be mastered, and the secret of hard-

paste porcelain manufacture was not discovered until the 18th century.

A factory at Saint-Cloud, founded by Pierre Chicaneau in the 1670s, made faience and a soft-paste porcelain that were yellowish in tone and heavily potted. Much use was made of molded decoration, which included sprigs of prunus blossom copied from the *blanc de Chine* of Tehua (see below *China: Ming dynasty*). Particularly common was a molded pattern of overlapping scales. Most examples are small, but there are some large jardinières (flowerpot holders) that are extremely handsome. The early painted wares were decorated in underglaze blue with typically Baroque patterns, including the *lambrequins* introduced at Rouen (Figure 125). Motifs derived from the designs of

Jean Bérain are also to be seen. Polychrome specimens, some of which were decorated in the style of Kakiemon, (see below *Japan: Edo period*), date from about 1730.

At Chantilly, the first soft-paste porcelain was decorated almost entirely in the Kakiemon style, and the body was invariably covered with a tin-glaze. The Japanese period ended about 1740. For some years thereafter simple Meissen styles were copied, in particular the German flowers. In 1753 an edict in support of the newly established factory at Vincennes forbade all other factories to manufacture porcelain or to decorate faience in polychrome; much Chantilly porcelain of the later period, therefore, is creamy white, decorated only with slight flower sprigs in blue underglaze. A transparent glaze was introduced in 1751 and replaced the very unusual practice of covering porcelain with a tin-glaze.

A factory at the Rue de Charonne, in Paris, was started by François Barbin in 1735 and removed to Mennecy in 1748. The early productions were in the manner of Saint-Cloud and Rouen. Later, some excellent flower painting was done, and figure modelling was excellent in quality. Small porcelain boxes from Mennecy, often in the form of animals, are much sought in the 20th century.

Vincennes and Sèvres

The most important of the French factories was established at Vincennes about 1738 and removed to a new building at Sèvres in 1756. Louis XV was a large shareholder in the original company and the factory eventually passed to the crown in 1759. It became state property in 1793, and has so remained.

The factory did not succeed in its attempts to make a practicable soft-paste porcelain until 1745. Much of the work at Vincennes consisted of naturalistic flowers with bronze stalks and leaves, sometimes in vases elaborately mounted in gilt bronze by the court goldsmith, Claude Thomas Duplessis, and others. Meissen was also copied for a short period, but the factory soon evolved its own style, which remained partly dependent on the use of high quality gilt-bronze mounts. A few glazed and painted figures were made, but these gave place in 1751 to figures of biscuit porcelain. In 1757 the sculptor Étienne-Maurice Falconet was appointed to take charge of modelling, a position he retained until 1766. Designs by the painter François Boucher were frequently used by Falconet and others; Boucher's influence is particularly strong during the lifetime of Louis XV's mistress, Mme de Pompadour, who took much interest in the factory. Later, some excellent work in this medium was done by the sculptors Augustin Pajou and Louis-Simon Boizot.

Both at Vincennes and Sèvres much use was made of coloured grounds in conjunction with white panels, which were used for decorative painting of the highest quality (Figure 126). These panels were surrounded by rich and elaborate raised gilding, which was engraved and chased (tooled). The most usual ground colours were a dark underglaze blue (*gros bleu*) and a brighter, overglaze (*bleu de Roi*); also used were turquoise blue, yellow, green, and *rose Pompadour* (often miscalled *rose du Barry* in England).

The porcelain of Sèvres was made to harmonize with the exotic and luxurious style of interior decoration that characterized French court circles. The soft-paste body was of superb quality; and, because the extremely fusible glaze partly remelted in the enamelling kiln, the colours sank into the glaze in a way hardly seen elsewhere.

Hard porcelain of Sèvres

The factory at Sèvres prosecuted the search for the ingredients of hard porcelain with vigour. They were eventually found, after a prolonged search, at Saint-Yrieix-la-Perche, near Limoges, in 1769. The new body was first manufactured soon after 1770, although for a number of years it was only used for biscuit figures. Later, it was employed for dishes and vases decorated in a severe but luxurious classical style. In 1800 the manufacture of soft porcelain was discontinued altogether.

A large number of smaller factories making hard porcelain sprang up, chiefly in and around Paris, in the second half of the 18th century. Some were patronized by members of the royal family, including Louis XVI's wife, Marie Antoinette. A number of provincial factories were also engaged in the same manufacture.

The Tournai factory, in Belgium, which began to make porcelain in 1751, enjoyed the patronage of the empress of Austria, Maria Theresa. Here, and in the associated factory at Saint-Amand-les-Eaux, the work of Sèvres was imitated on a considerable scale.

Germany and Austria. While Germany is principally noted for its superb porcelain, the stoneware of the Rhineland is no less noteworthy. A great deal of faience was also made, though this was less important.

The earliest distinctive type of ware made in markedly Germanic style (*c.* 1350) was the *Hafnergeschirr* ("stove maker vessel"). Originally the term referred to tiles, molded in relief and usually covered with a green glaze, which were built up into the large and elaborate stoves needed to make mid-European winters tolerable. Jugs and other vessels made by these stove makers, however, came to be called Hafner ware by extension when their manufacture began about the mid-16th century. The work of Paul Preuning of Nürnberg is an example of this kind of ware. He decorated his pottery with coloured glazes kept apart by threads of clay (the cloisonné technique). In Silesian Hafner ware, on the other hand, the design is cut out with a knife, the incisions preventing the coloured glazes from mingling. The earliest German stove tiles are lead glazed. Tin glazes came into use about 1500.

Hafner ware

After these beginnings, German pottery developed in two distinct classes: stoneware and tin-glazed earthenware.

Stoneware. The stoneware (*Steinzeug*) came mainly from the Rhineland and, in particular from Cologne, Westerwald, Siegburg, and Raeren (the latter now in Belgium). Manufacture probably began in Cologne about 1540. The body of the stoneware is extremely hard and varies from almost white (Siegburg) to bluish gray (Westerwald); a brown glaze over a drab body is also to be seen (Raeren). The surface is glazed with salt—no more than a smear glaze, pitted slightly, like orange peel. A smooth, though still very thin, glaze was achieved by mixing the salt with red lead. Particularly popular at Cologne in the late 16th century was the "bearded-man jug" (*Bartmannkrug*), a round-bellied jug with the mask of a bearded man applied in relief to the neck. This type was sometimes called a "Bellarmine" in England; the mask was thought to be a satire on the hated Cardinal Robert Bellarmine (Bellarmino), but there is no authority for this assumption. In England, where they were imported in large quantities, they were also known as graybeards. The term tigerware was also used for the mottled brown glaze over a grayish body.

Some of the earliest German stoneware is notable for its remarkably fine relief decoration in the Gothic style. Oak-leaf and vine-leaf motifs were common, as were coats of arms on medallions. The applied relief and stamped decoration was, at times, most elaborate, and the thin glaze lent it additional sharpness and clarity. Reliefs of biblical subjects appear on tall, tapering tankards (*Schnellen*), which were provided with pewter or silver mounts. The *Doppelfrieskrüge* were jugs with two molded friezes (usually portraying classical subjects) around the middle.

Gerald Reitlinger, London, photograph, Wilfred Walter

Figure 127: Gray stoneware jug decorated with cobalt and salt glaze, from the Westerwald region, Germany, early 17th century. English silver mounts are dated 1652. Height 24.1 cm.

They and the tankards were made in Raeren brownware by Jan Emens, surnamed Mennicken, in the last quarter of the 16th century. Emens also worked in the gray body that was used at Raeren at the turn of the century, employing blue pigment to enhance the decoration (Figure 127). At a later date, blue and manganese pigments were used together, and this practice continued throughout the 17th century. Figures were sometimes set in a frame reminiscent of Gothic architectural arcades, and inscriptions of one kind or another are fairly frequent.

The style of the stonewares gradually fell into line with the prevailing Baroque style, particularly toward the end of the 17th century. At Kreussen, in Bavaria, a grayish-red stoneware was covered with a brown glaze, and the molded decoration was often crudely picked out with opaque overglaze colours that had a tin-glazed base. The earliest dated specimen is 1622, which was the first time overglaze colours had been used on pottery in Europe. The technique, learned from Bohemian glass enamellers, was to have some influence in France as well as in Germany.

German stoneware was popular abroad; during the 17th century Sieburg even exported to Japan.

An extremely important type of stoneware was first made shortly before 1710 at a factory at Meissen that was under the patronage of Augustus the Strong, elector of Saxony and king of Poland. It was discovered by E.W. von Tschirnhaus (1651–1708) and J.F. Böttger (1682–1719) during their researches into the secret of porcelain manufacture. It usually varies from red to dark brown and is the hardest substance of its kind known. An almost black variety was termed *Eisenporzellan* ("iron porcelain"), and a black glaze was devised by Böttger to cover specimens of defective colour. Decoration is usually effected by means of applied reliefs, although the black-glazed specimens were sometimes decorated with lacquer colours, as well as with gold and silver. Silvering was not uncommon and was also practiced in other German centres during the early part of the 18th century on both stoneware and porcelain.

Meissen stoneware

A particular feature of Meissen stoneware is the incised decoration done by lapidaries on the engraving wheel. Many specimens were engraved with coats of arms, and grinding into facets (the *Muscheln* pattern) was also practiced. The same methods were used to give a plain surface a high polish. Metal mounts, common Rhenish stoneware, also were sometimes accompanied by insetting precious and semiprecious stones.

Because of the vogue for porcelain, stoneware manufacture declined and was finally abandoned about 1730.

Tin-glazed ware. Faience factories were so numerous that it is only possible to mention the most important of them. Perhaps the earliest tin-glazed wares other than stove tiles are the jugs in the form of owls (with detachable heads to be used as cups) that came from Brixen (Bressanone), in the Tirol. Their shape and style no doubt inspired the later owl and bear jugs made in England during the 18th century. These owl jugs (*Eulenkrüge*) were, at first, used as prizes in archery contests and were sometimes repeated in Rhenish stoneware.

The first manufacture of faience on a considerable scale took place at Nürnberg, and some dishes in the Italian style still survive. Much more is known, however, of the productions of Kreussen, which is chiefly of interest for its blue-and-white faience jugs. The outline of flowers painted in blue is almost cross-sectional in style and terminates in a small spiral—hence the name spiral family.

A factory of Hanau, near Frankfurt am Main, was started in 1661 and remained in operation until 1806. Many of the early wares were decorated with Chinese motifs. A type of jug with a long narrow neck, the *Enghalskrug*, was made in Hanau. Some have a globular body (sometimes copied in China and Japan in blue painted porcelain); others, a spirally fluted body and a twisted handle. Pewter or, less often, silver covers were common. The painting includes coats of arms, landscapes, and biblical subjects. Groups of dots amid strewn flowers (*Streublumen*) are characteristic. Realistically painted German flowers appear shortly before mid-18th century. Most painting is in blue, manganese, and the other less often used faience colours. Overglaze colours do not seem to have been used.

A factory in Frankfurt am Main itself was founded in 1666. Imitations of Chinese motifs as well as biblical subjects were very popular. The blue is brilliant, and the surface usually suggests the use of a transparent overglaze. Narrownecked jugs were commonly made and are sometimes difficult to distinguish from those of Hanau. This centre closed about 1740. At Nürnberg a later factory was established about 1712, continuing until about 1840. Most of the subjects used at Frankfurt and Hanau were repeated at Nürnberg, as well as designs based on the the Rococo engravings of J.E. Nilson (1721–88), which were also popular at many of the porcelain factories. The Rococo style, which spread from France to Germany about the second quarter of the 18th century, is reflected both in the forms and the decoration.

Wares of Bayreuth

The wares of Bayreuth are particularly interesting. Early products were painted with a misty blue, but overglaze colours were speedily adopted. "Leaf and strapwork" (*Laub-und-Bandelwerk*) was a much used type of motif, and excellent work was done by A.F. von Löwenfinck (who is known particularly for his work on porcelain) and Joseph Philipp Danhofer. Perhaps the finest 18th-century faience was made by the factory at Höchst, near Mainz, which also manufactured porcelain. Decoration was usually in overglaze colours, and landscapes, figure subjects, German flowers, and chinoiseries (European delineations of the Chinese scene with a strong element of fantasy) are of a much higher quality than elsewhere. Faience thus decorated with colours applied over the glaze, as on porcelain, was termed *Fayence-Porcellaine* during the 18th century.

An important aspect of both faience and porcelain decoration in Germany is the work of the studio painters, or *Hausmaler,* who brought undecorated faience and porcelain from the factories and painted it at home, firing the decoration in small muffle kilns. For this reason, their work was done in overglaze pigments. At first they mostly used the *Schwarzlot* technique—decoration in a black, linear style that was nearly always based on line engravings. Faience thus decorated dates from about 1660 and is the work of Johann Schaper (died 1670), who had been a Nürnberg glass painter, J.L. Faber, and others. Polychrome enamel decoration was developed by another glass painter, Abraham Helmhack (1654–1724), who mastered the technique as early as 1690, many years before it was adopted by the factories. The more important studio painters are Johann Aufenwerth and Bartholomäus Seuter of Augsburg, J.F. Metszch of Bayreuth, the Bohemians Daniel and Ignaz Preussler, and Ignaz Bottengruber of Breslau. The work of the latter is particularly esteemed.

Toward the end of the 18th century a number of German factories, including some already making faience, made lead-glazed earthenware (*Steingut*) in imitation of Wedgwood, while a factory at Königsberg (now Kaliningrad) imitated Wedgwood's black basaltes body.

Porcelain. The earliest hard porcelain, produced by the factory at Meissen, is smoky in tone, but some improvements were made in 1715 and others in the following decade. Many early specimens were painted with a limited range of overglaze colours of good quality, including a pale violet lustre derived from gold that remained in use until about 1730. In 1720 a painter from Vienna, Johann Gregor Höroldt, was appointed chief painter (*Obermaler*) to the factory; he was responsible for introducing a new and much more brilliant palette, as well as some ground colours (*Fond-Porzellan*). The earliest ground colour to be noted is a coffee brown termed *Kapuzinerbraun,* which was invented by the kilnmaster Samuel Stölzel. The use of blue underglaze proved difficult, and little work of the kind was done. Overglaze painting, on the other hand, was of fine quality and includes topographical subjects, figure subjects based either on harlequin, pierrot, and other characters of the Italian comedy or on the style of the painter Jean-Antoine Watteau and his followers, and flowers in the Oriental style (called *indianische Blumen*) as well as native flowers (*deutsche Blumen*) taken from books of botanical illustrations. A series of harbour scenes from engravings of Italian ports were mostly executed by C.F. Herold (cousin to the *Obermaler*) and J.G. Heintze. Perhaps the most important early wares are the chinoiseries, which appear in great variety. The first work of the kind, much of it painted by the *Hausmaler* Bartholomäus Seuter, is in gold silhouette followed by polychrome painting after designs by the *Obermaler.* The figures are painted in three-quarter length. *Indianische Blumen* motifs were used, and Arita decorations, particularly those of Kakiemon (see below *Japan: Edo period*), were closely copied.

Figure modelling

Little figure modelling was done until about 1727, when the sculptor Johann Gottlob Kirchner was appointed *Modellmeister* and asked to make some colossal figures of animals for the Japanische Palais, the building that housed Augustus the Strong's porcelain collection. Because the medium was unsuited to work of this kind, most of the surviving examples are spectacular and magnificent failures. After the death of Augustus the Strong in 1733 large-scale modelling was practically discontinued, and the new *Modellmeister,* Johann Joachim Kändler, turned his attention to small figures suitable for decorating the dining table.

Assisted by other modellers, Kändler soon made the figures of Meissen fashionable throughout Europe. The first important Rococo work in porcelain appears in Saxony after 1737 when Kändler started to make the Swan service—perhaps the best known of all porcelain services. It is decorated with such motifs as swans, nereides, and tritons. Rococo Meissen was widely sought.

Meissen was the most influential European factory until the beginning of the Seven Years' War in 1756, when it was taken by the Prussians. From then until 1763 it was operated by nominees of Frederick the Great, who virtually looted the factory. By the end of the war, leadership had passed to Sèvres, and the work of Meissen for the next 50 years is much less important than formerly. The transitional Louis XVI style of *c.* 1763–74 is typified by the figure modelling of Michel Victor Acier, who came to the factory to share the position of *Modellmeister* with Kändler in 1764. From 1774 to 1814 the Neoclassical style was increasingly used, and the designs of Sèvres and of Wedgwood (Wedgwoodarbeit) were copied.

Few marks have been so consistently abused as that of the crossed swords of Meissen. Since the 18th century, it has been added to all kinds of unlikely specimens.

The other German factories of the period were, for the most part, established with the aid of runaway workmen from Meissen and Vienna, where Claudius Innocentius du Paquier had started a factory in 1719 with the aid of two men who were themselves from Meissen. Early Vienna hard-porcelain wares are highly prized. Much use was made of leaf and strapwork patterns, and excellent work was done in black monochrome (*Schwarzlot*). The factory passed to the state in 1744, and its later work is competent without being distinguished. Between 1784 and 1805 it became noted for elaborate gilding and coloured grounds, with minutely detailed painting, after Angelica Kauffmann and others, in reserved white medallions.

The Vienna factory provided a number of wandering arcanists (men who possessed the *arcanum,* or "secret," of hard-porcelain manufacture), two of whom helped to establish the Höchst factory, which began manufacture about 1752. This factory is principally noted for excellent figures in the Neoclassical style by Johann Peter Melchior and for the work of Simon Feilner.

A factory in Berlin, started in 1761 and acquired by Frederick in 1763 when he relinquished his hold on Meissen, produced wares with painted decoration of high quality. The decoration made much use of mosaic patterns—detailed diapers (small repeated motifs connecting with one another or growing out of one another with continuously flowing or straight lines) painted over a coloured ground. A large service made in 1819 for presentation to the Duke of Wellington and decorated with scenes from his battles is now in Apsley House, London.

Nymphenburg figures

There is much interest in the figure modelling of Franz Anton Bustelli, who worked at Nymphenburg, a suburb of Munich. The factory, which is still in operation, was started about 1753. Bustelli became *Modellmeister* in 1754 and retained the position until his death in 1763. His magnificent series of figures based on the Italian comedy are the most important expression of Rococo in German

porcelain. The painted wares of the factory were also of fine quality.

Some excellent figures were made at Fürstenberg, where hard porcelain was first manufactured in 1753, and at Frankenthal by such notable modellers as J.W. Lanz, the cousins J.F. and K.G. Lücke, and Konrad Linck. Ludwigsburg, started in 1758, produced porcelain that was grayish in colour and more suitable for figure modelling than for service ware. The figures of artisans by an artist known as the Modeller der Volkstypen (modeller of folktypes) are original and pleasing, and the sculptor, Wilhelm Beyer, did good work in the Neoclassical style.

The Netherlands. During the 17th century, red stoneware was made by Ary de Milde of Delft and others in imitation of the wares of I-hsing (see below *China: Ming dynasty*). Creamware was manufactured at several places at the end of the 18th century. Most Dutch pottery of the period, however, is tin glazed.

Italian potters had settled in Antwerp by 1525, and surviving examples of tin-glazed ware from this period are in the Italian style. Manufacture was concentrated to a great extent in Delft soon after the beginning of the 17th century. By about 1650 the large brewing industry began to decline, and the old buildings were taken over by potters who retained such names as The Three Golden Ash-Barrels, The Four Roman Heroes, and The Double Jug for their potteries. The craftworkers of the town were organized into the Guild of St. Luke, which exercised a considerable amount of control over apprenticeships and established a school of design.

In the 17th century the Dutch East India Company, chartered in 1602, imported Chinese and Japanese wares in great quantities, and the taste for Eastern decoration rapidly ousted Italian fashions. For the greater part of the 17th century decoration was in blue, and Chinese porcelain was closely imitated. In wares of the best quality this imitation is so exact that, without a fairly close inspection, it is possible to mistake them for the originals. Western decorations—biblical and genre scenes, landscapes and seascapes—were carried out in styles similar to Dutch paintings of the period. Tilework was frequently undertaken; many individual tiles have survived, although large panels made up of many tiles are very rarely complete (Figure 128). Blue painting was followed by the use of the usual underglaze faience colours, the outline (known as *trek*) being first drawn with blue or manganese and then filled in. Before firing, the object was covered with an additional transparent lead glaze known as *kwaart*, which made the surface more brilliant. Red was a difficult colour; often when it was to be used, an unpainted space was left during the first firing, and the red was applied afterward and fired at a lower temperature. Gilding is found on the finer specimens and required a further firing. Overglaze colours were introduced by Zacharias Dextra about 1720, and the Chinese *famille rose* patterns were frequently imitated. Among the rarer and more showy examples of delft may be numbered the *Delft dorée*, on which gilding is lavish, and the *Delft noir*, which has a black ground (suggested by Chinese lacquer work) in conjunction with polychrome decoration. Work of this kind is often attributed to Adriaen Pijnacker.

Delft tiles

By courtesy of the Victoria and Albert Museum, London, photograph, A.C. Cooper Ltd

Figure 128: Tin-glazed earthenware wall tile with medallion portraits of William and Mary, Delft, "Greek 'A'," factory of Adrianus Kocks, c. 1694. William III of England commissioned these large tiles for Queen Mary's dairy at Hampton Court. In the Victoria and Albert Museum, London. Height 62 cm.

Marks on Dutch delft are extremely unreliable, for many later copies were given the earlier marks of important potteries, especially during the 19th century.

Britain. The medieval pottery of England was affected little by outside influences. Moreover, poor communications prevented the industry from concentrating in any one place; most wares, therefore, are made of local clay by local craftsmen. The potters worked alone or in extremely small groups, and their tools were few and simple. The clay used for the body ranges from buff to red, or, when fired in a reducing atmosphere, from gray to almost black. As with much Japanese pottery, little effort was made to disguise the method by which the vessel was formed, so that pronounced ridges are frequently visible. Both relief and inlaid decoration are found, especially on tiles, and brushed slip was also used to add simple patterns.

Unglazed ware was common, especially in the early period, but a soft lead glaze came into more general use later, the knowledge probably being derived from France. The early glaze varied between yellow and brown according to the iron content of the clay, although a group having a particularly rich brown glaze was made by first washing the pot with slip containing manganese. The use of copper oxide to give a rich green of variable colour dates from the 13th century. During that period, the green, buff, and brown glazes were used in conjunction. Cistercian wares, made in the monasteries before their dissolution in 1536–39, are more precisely finished. They have a dark-brown glaze over a stoneware body and are sometimes decorated with white slip or incised. By far the greatest number of surviving specimens are jugs and vessels for storing liquids; since they have almost always been excavated, a reasonably perfect specimen is a rarity.

Tin-glazed ware. Lead-glazed wares tended to die out after tin glaze reached England via the Netherlands about 1550. At first it was called gallyware, but, with the rise of the Dutch manufacturing centre at Delft, the ware came to be called delft. Its popularity was due to the fact that it could be painted in bright colours. The earliest surviving examples are the Malling jugs, so called because an early specimen of the kind was preserved in the church at West Malling, Kent. These were almost certainly made in London. The colour varies from turquoise to black; a variety with a blue ground flecked with orange was probably suggested by the tigerware from the Rhineland. The jugs usually have silver or pewter mounts. Similar mounts, often of English manufacture, are to be seen on Rhenish jugs imported into England and occasionally on Turkish jugs of about the same period.

Malling jugs

By 1628 a flourishing factory had been established at Southwark, London. Influenced by some Chinese blue-and-white porcelain of the Ming reign of Wan-li (1573–1620), some surviving specimens are decorated in blue, with birds amid floral and foliate motifs. Almost contemporary are some large dishes painted in polychrome colours. The earliest (1600), which is in the London Museum, bears the following couplet: "The rose is red the leaves are grene/God Save Elizabeth our Queene." The dish has a border of blue dashes and is a forerunner of the so-called blue-dash chargers that were popular later in the century. These were decorated with biblical scenes (Adam and Eve being a special favourite), crude portraits of the

kings of England, ships, armorial bearings, and the like. The influence of Italian maiolica and Chinese porcelain can be seen in the border designs.

Many wine bottles are extant, often with the name of the wine (Sack, Claret, etc.) painted in blue and a date. Others are more elaborately decorated, a few are in polychrome.

Toward the end of the 17th century service ware became more frequent (although tea ware was now scarce). Blue-and-white was still made in large quantities, but a polychrome palette was more in evidence, and the influence of Dutch potters is often obvious.

Chinese influence, which had been particularly strong in the early part of the 18th century, tended to persist, particularly at Bristol. The Rococo style was used to a limited extent. Later, some not very successful attempts were made to utilize The Neoclassical forms. Overglaze colours on tin-glazed wares appear after mid-century. These colours, a special pallet now called Fazackerly colours, were probably used only at Liverpool.

Fazackerly colours

The main centres of production of tin-glazed ware were in London (Southwark and Lambeth), Bristol, and Liverpool, although there were smaller potteries elsewhere. One of them—Wincanton in Somerset—made frequent use of manganese, which produces purple and purplish-black colours. The tin glaze fell into disuse about the turn of the 18th century, its place having been taken by Wedgwood's creamware. (In the mid-20th century manufacture has been successfully revived at Rye, Sussex.)

17th-century slipware. Wares decorated with dotted and trailed slip were made at Wrotham, Kent, and in London during the first half of the 17th century. Wrotham is noted principally for drinking mugs with two or more handles, known as tygs; and London for dishes with such pious exhortations as "Fast and Pray," obviously inspired by the Puritans. Manufacture was also started in Staffordshire, and many surviving examples were signed by the potter in slip. The work of Thomas Toft is particularly valued. The best work of this kind was done before the end of the 17th century, and although it may fairly be described as peasant ware, many of the earlier specimens are vigorously decorated and amusing. Manufacture continued until the end of the 18th century.

Stoneware. The popularity of Rhineland stonewares in England, as well as that of the newly imported Chinese stoneware teapots from I-hsing kilns (see below *China: Ming dynasty*), led to attempts to imitate both kinds. The first patent for making copies of porcelain and Cologne ware known to have been exercised was awarded to John Dwight (*c.* 1637–1703) of Fulham in 1671. In addition to German stoneware, he made a brown-glazed stoneware decorated with stamped ornament that was continued at Fulham after his death and has been extensively reproduced since. He probably never made any porcelain, but he mentions red china, which can only refer to imitations of the I-hsing stoneware.

The brothers John Philip and David Elers, of German origin, made red stoneware at a factory in Staffordshire. It is difficult to separate their work from that of Dwight (at Fulham), on the one hand, and that of their Staffordshire imitators, on the other. Most wares are decorated with stamped reliefs, the Chinese prunus blossom being comparatively common. The tendency to utilize patterns from silverwork, which is apparent on some examples, may be connected with the fact that the Elers had been silversmiths. The Elers' migration to Staffordshire perhaps can be regarded as the starting point for the large modern industry that has grown up in that area. Certainly from this time onward Staffordshire wares tend to lose their peasant character and to approach a factory-made precision that was to be general by the end of the 18th century.

Salt-glazed stoneware

The earlier red- and brown-glazed stonewares were replaced about 1690 by a salt-glazed stoneware that was regarded as an acceptable substitute for porcelain. It varies in colour from drab to off-white, the glaze on later specimens often having a richer, more glassy appearance due to the addition of red lead to the salt. One of the earliest varieties is decorated with reliefs stamped from pads of clay that were applied to the surface.

18th-century developments. The "scratched-blue" class of white stoneware dates from about 1730 and is decorated with incised patterns, usually touched with blue. Decoration is floral, and inscriptions and dates are fairly frequent. Its manufacture continued until about 1775.

From the 1730s molded patterns in relief were popular, the clay being pressed into molds of metal, wood, or fired clay. The introduction of plaster of paris molds around 1745 gave much greater scope and led to the development of intricate shapes in the finer varieties of white stoneware. The patterns greatly increased in sharpness and elaborate piercing is to be seen.

Transfer printing was first used about 1755, possibly at Liverpool, which produced wares of all kinds, including tiles, using this decorative technique.

The earliest use of overglaze colours belongs to the same period—previously, white wares had been sent to Holland for decoration. The Englishman who first mastered the technique was William Duesbury. Established as a decorator in London by 1751, he concentrated on painting porcelain, but he also seems to have overglaze-painted stoneware from Staffordshire. Some extant brilliantly painted figures are probably from his studio. A little earlier than Duesbury's overglaze-painted figures are the uncoloured pew groups, which consist of two or three figures seated on a high-backed settle or pew, modelled in a primitive and amusing fashion. A rich blue overglaze ground, often called Littler's blue after William Littler, who is thought to have invented it, was much used on the salt-glazed stoneware, as well as the porcelain, made at Longton Hall, a factory that operated in Staffordshire from about 1750 to 1760 and that was also associated with Sittler.

John Astbury is particularly associated with a type of brown-glazed ware decorated with stamped pads of white clay. Some of the earliest Staffordshire figures in brown and white clay covered with a lead glaze have been attributed to Astbury.

Thomas Whieldon (1719–95) of Fenton Low, Staffordshire, manufactured agateware—that is, ware made by combining differently coloured clays or by combing together different colours of slip. In the former method the clays were usually laid in slabs, one on the other, and beaten out to form a homogeneous mass in which the colours were inextricably mingled. Agatewares seem to have been made in Staffordshire between 1725 and 1750, the earlier specimens being salt glazed, while the later ones were covered with a colourless lead glaze. Whieldon

Agateware

is most famous for his use of coloured glazes that were mingled to give a clouded or tortoiseshell effect and were used on an earthenware body, sometimes over molded decoration. A few naïvely modelled figures with this type of glaze are attributed to him. From 1754 to 1759 he was in partnership with Josiah Wedgwood, who developed the fine green and yellow glazes to decorate molded wares in the form of pineapples, cauliflowers, and the like.

Coloured glazes were also used by Ralph Wood I (1715–72) of Burslem, Staffordshire, for decorating an excellently modelled series of figures in a creamware (lead-glazed earthenware) body, the finest, perhaps, a mounted Hudibras (Figure 129) in the Victoria and Albert Museum. Many of these figures are attributed to the modeller Jean Voyez, who was much influenced by the work of Paul-Louis Cyfflé at Lunéville (see above *France and Belgium*). Ralph Wood I is also noted for the typical English Toby jug (first made soon after 1700), which is a beer jug in the form of a man, usually seated and holding a pipe and a mug, the hat (where present) forming a detachable lid. Very popular, it continued in production for many years. Enoch Wood, another member of the family, joined Ralph Wood II in partnership as Enoch Wood & Co., which lasted until 1790. They made most of the wares current in Staffordshire at the time, as well as some excellent figures decorated with overglaze colours.

Wedgwood

Josiah Wedgwood (1730–95), the most famous of all the Staffordshire potters and the most important exponent of Neoclassicism in the field of pottery, is celebrated chiefly for his fine jasper and black basaltes stonewares, but his creamware was undoubtedly the more influential in the 18th century. It was well finished and clean in appearance, with simple decoration in good taste, often in the popular Neoclassical style. His wares appealed particularly to the rising bourgeois class, both in England and abroad, and porcelain and faience factories suffered severely from competition with him. Surviving factories switched to the manufacture of creamware (*faience fine* or *faience anglaise*), and the use of tin glaze almost died out.

Wedgwood secured the patronage of Queen Charlotte (wife of King George III) for his creamware in 1765 and renamed it Queen's ware. Much of it was transfer printed by John Sadler and Guy Green at Liverpool. Evidence of its popularity and importance is provided by the enormous service of 952 pieces made for Catherine the Great's palace of La Grenouillière, in St. Petersburg.

The basaltes ware, also called black porcelain or Egyptian ware, was a type of stoneware introduced about 1768. Like the jasper that followed, it was used almost entirely for ornamental work—vases, ewers, candlesticks, plaques, medallions, and tea and coffee ware. Some of it was painted in what Wedgwood called encaustic enamel in imitation of Greek red- and black-figure vases, but most of the decoration was either molded and applied or incised by turning on a lathe.

Jasperware

Jasper, introduced about 1775, is a fine-grained white unglazed stoneware, slightly translucent when thinly potted or fired above the normal temperature. Undoubtedly it was inspired by the biscuit porcelain of Sèvres. Its name derives from the fact that it resembles the natural stone in hardness. At first the body was stained blue (with applied decoration in white). Other colours, such as sage green, lilac, black, and yellow, followed speedily. Like basaltes, jasper was used mainly for ornamental wares, but perhaps the most interesting products are the portrait medallions of contemporary notables. Vases do not appear to have been made until after 1780 (Figure 130). In 1790 Wedgwood produced the first copies of the Portland vase, a magnificent Roman cameo glass vase of dark blue glass decorated with white figures, at that time owned by the Duke of Portland but now in the British Museum. The vase was reproduced in later years, particularly in Victorian times both by Wedgwood in jasper and by Northwood in glass. Wedgwood's jasperwares were imitated in biscuit porcelain at Sèvres, and Meissen produced a glazed version called *Wedgwoodarbeiten*. Less influential was the red stoneware (*rosso antico*), which sometimes had an enamelled decoration of classical subjects, and caneware, a buff stoneware.

Lustre pigments introduced into England toward the end of the 18th century were used in a manner quite different from the earlier styles of other countries (see above *Spain* and *Islāmic*). To simulate silverwork, wares were completely covered with platinum lustre, which remains unchanged in colour after firing (silver itself yields a pale straw colour); the amount of metal used was extremely small. Such wares were known as poor man's silver. Wares were also painted or stencilled with lustre patterns. The most valuable type commercially were the resist lustres, which have a lustred background and the pattern reserved in white. They were made by painting or stencilling the pattern on the glaze with shellac, which resisted the subsequent application of the metallic pigment. Silver lustre was rarely used, but gold lustre, which gives variable colours from pink to purple, was fairly common. (Copper, the colour of which remains more or less unchanged in its lustre form, was used throughout the 19th century for common wares.)

Poor man's silver

Porcelain. A factory for porcelain manufacture, using a soft-paste body similar to that of Saint-Cloud, was established in Chelsea, London, about 1743 by Charles Gouyn and Nicolas Sprimont, the latter a silversmith. The rare surviving specimens include jugs molded in the form of goats and further decorated with an applied bee, obviously based on a silver prototype that no longer exists. (Extant examples of the latter are 19th-century forgeries.) These goat and bee jugs are often marked with an incised triangle, which was then the mark in use. About 1750 a new body was adopted, together with the familiar mark of an anchor, which was raised on a small medallion until about 1752, painted in red until about 1756, and executed in gold thereafter. The work of the Chelsea factory was extensively influenced by Meissen until about 1756, the styles of Sèvres superseding it in the gold-anchor period. Wares marked with either the raised or the red anchor are the most highly valued; the painting of these is excellent in quality. Some of the best wares were painted by an Irish miniaturist, Jeffrey Hamet O'Neal. The gold-anchor-marked wares are noted for rich gilding and some fine coloured grounds that, on occasion, rivalled those of Sèvres (Figure 131). The figures in the later Rococo style are generally inferior to those of the earlier red-anchor period. Some Chelsea porcelain from 1760 onward was painted in the studio of James Giles of Clerkenwell. The factory was bought by William Duesbury of Derby (see below) in 1770

Artists' marks determine value

Figure 131: "The Music Lesson," enamelled soft-paste porcelain, English, Chelsea, gold anchor period, *c.* 1765. In the Metropolitan Museum of Art, New York. Height 38.1 cm.

and entered a phase known as the Chelsea-Derby period. The Neoclassical style was introduced together with the figure in biscuit porcelain made fashionable by Sèvres. It closed finally in 1784.

A group of figures, the best known examples of which are those portraying a girl in a swing, were made in the 1750s—possibly at Chelsea but more probably at a short-lived factory staffed by workmen who had seceded from Chelsea. A class of figures characterized by an apparent retraction of the glaze from the base—dry-edged figures—are attributed to a factory established at Derby about 1750. This enterprise apparently petered out and another factory in Derby was started in 1756 by Duesbury (who was later to buy the Chelsea factory). It advertised itself as the second Dresden and is noted toward the end of the century for the excellence of its painting by Zachariah Boreman, William Billingsley, and others.

Longton Hall in Staffordshire made figures and a good deal of service ware molded in the form of leaves. A rich blue ground (Littler's blue) was used on porcelain and salt-glazed wares alike. Its wares are rare and much sought.

The Bow factory (London) was started as early as 1744 with the aid of clay brought from Virginia by the American settler Andrew (André) Duché, who had discovered the secret of manufacture quite independently some years before (see below *Colonial America*). An amusing and primitive class of Bow figures was executed by an anonymous artist known as the Muses Modeller, because the most typical figures portray the Muses. Generally speaking, Bow wares are unsophisticated, and the factory obviously catered to prosperous tradesmen, a market ignored by Chelsea. An important technical innovation took place at Bow in 1750, when calcined bones were added to the porcelain body. This was the first major departure from the French soft-porcelain formula, which was fundamentally a mixture of clay and ground glass. Bone ash was added to soft porcelain by Chelsea about 1755, by Lowestoft (which mainly copied Bow styles) in 1758, and by Duesbury to Derby porcelain in 1770, when he purchased the Chelsea factory.

Development of English bone china

About 1800 at his factory at Stoke-upon-Trent, Staffordshire, Josiah Spode the Second added calcined bones to the hard-porcelain formula to produce the standard English bone-china body (see below *19th century*).

Another variation on the original soft-porcelain body was introduced at a factory in Bristol started by Benjamin Lund about 1748. Clay was mixed with a fusible rock called steatite (hydrous magnesium silicate), the principle being similar to that used in the manufacture of hard porcelain. This factory was transfered to Worcester in 1752 and still manufactures fine porcelain. In the 18th century, scale grounds, which consisted of patterns of overlapping scales in various colours, were particularly popular. Transfers taken from engraved plates were also extensively used for decoration. After 1783 wares show a progressive decline in taste. A second factory was established at Worcester by Robert Chamberlain in 1786 (see below *19th century*).

William Cookworthy discovered the secret of hard porcelain independently after many years of experiment. In 1768 he opened a factory at Plymouth (which was transferred to Bristol in 1770) that made figures in the style of Bow and Longton Hall. Richard Champion acquired the patent for hard porcelain in 1772 and manufactured tableware Neoclassical in style and excellent in quality. The patent was bought by a syndicate that established a factory at New Hall, Staffordshire, in 1782 and made a humble variety of wares for about 40 years.

Scandinavia. The faience industry spread to Scandinavia mainly because of migratory workmen from Germany. A number of factories in Denmark, Norway, and Sweden during the 18th century made faience and creamware in the English manner. A distinctive Scandinavian production was that of bowls, made in the shape of a mitre, for a kind of punch called bishop. The most important factories are those of Rörstrand and Marieberg (Koja) in Sweden. A typical Rococo concept to come from Marieberg is a vase standing at the top of a winding flight of steps. Called a terrace vase it is often decorated with a rabbit or some other animal.

In 1774 a factory at Copenhagen directed by Louis Fournier, a modeller from Vincennes and Chantilly, began the manufacture of true porcelain. The factory was acquired in 1779 by King Christian VII of Denmark and Norway. In 1789 the factory started work on an enormous service, originally intended for Catherine the Great, each piece of which was painted with a detailed picture of a Danish flower. This service, the "Flora Danica," is now in Rosenborg Palace, Copenhagen. Numerous skillfully made figures were also produced. The factory continues to produce fine porcelain.

Service for Catherine the Great

Switzerland and Russia. A factory started near Zürich in 1763 and directed by Adam Spengler made both faience and porcelain and, after 1790, creamware. Delicate figures, some modelled by J.V. Sonnenschein from Ludwigsburg, and good-quality service ware were produced.

The factory of St. Petersburg was established about 1745. Later production was on a fairly large scale, and the work of Sèvres and Meissen was freely copied. Some good original work was also done, and well-modelled figures of Russian peasants were made toward the end of the century. Even better figures were made at a factory in Moscow founded about 1765 by an Englishman named Francis Gardner. Many factories at Moscow and elsewhere in Russia were established during the 19th century.

Colonial America. There is little detailed information about the pottery made by the early European settlers in North America. Most of it was manufactured locally for local needs and from the clays that were nearest to hand. Since most of these contained iron in varying quantities, the pottery body burned to colours between buff and red. Until kilns capable of reaching a high temperature were constructed, manufacture was limited to earthenware. Lead glazes were commonly used. Slips, both as a wash and as trailed decoration, were employed, and sgraffito decoration is known. Most of this pottery was made for practical rather than decorative purposes. A few potteries were established in the 17th century in Virginia, Massachusetts, and New Jersey; and in eastern Pennsylvania, German settlers started work as early as 1735 making slip-painted and sgraffito earthenware in their own traditions.

Perhaps the most important development in colonial America took place in Savannah, Georgia, where Andrew Duché started a pottery about 1730. He interested himself in the manufacture of porcelain and discovered the china clay and feldspathic rock necessary to its manufacture. By

1741 he appears to have made a successful true porcelain but failed to gain adequate financial assistance to develop it. He therefore travelled to London, arriving in 1744, and tried to sell the secret to the founders of the Bow factory in London. Their interest is certain, since the patent specification subsequently filed specifically mentions *unaker*, said to be the Cherokee name for china clay. Duché returned to Virginia by way of Plymouth and there spoke with William Cookworthy, later to be the first manufacturer of true porcelain in England. It is still not known to what extent Duché actually manufactured porcelain; but since the *Bristol Journal* for November 24, 1764, refers to the import of some specimens of porcelain said to have been made in Georgia, there is little doubt that the first porcelain to be made in an English-speaking country came from North America. The Cherokee clay was shipped to England from time to time during the 18th century. Wedgwood imported several tons of it to use in the development of the jasper body.

Hard porcelain in America

By 1765 potteries were being established on a sufficient scale to warrant an attempt to recruit workmen from Staffordshire. Wedgwood wrote at the time: "They had a agent amongst us hiring a number of our hands for establishment of new Pottworks in South Carolina."

The manufacture of tin-glazed ware began in Mexico soon after the Spanish Conquest in the first half of the 16th century. Spanish styles predominated, especially that of Talavera, but Chinese influence occurs in the 18th century. The wares became a kind of inspired folk pottery in the 19th century.

19TH CENTURY

There is a fundamental difference between work done before the Industrial Revolution, the effect of which began to be felt in the pottery industry before 1800, and that done subsequently. A student of the older wares, particularly those of the East, may find much of the later work difficult to accept because of its machine finish. When an object is made by hand it is never exactly the same as any other object, nor are the processes by which it has been formed and decorated disguised. Consider, for example, a Sung dynasty pot or a specimen of Japanese tea ceremony ware, whose imperfections of finish by factory standards are an integral part of their beauty and character, or the glaze of a *Kuan* vase, which would lose its individuality if it possessed the smooth finish of a factory-made specimen. The technical precision of the 19th century, which made its products indistinguishable from one another, and the careful concealment of the means by which the end had been achieved, were both unprecedented and deleterious. Style and craftsmanship degenerated steadily in the factories. The situation was aggravated by the Great Exhibition of 1851, which encouraged manufacturers throughout Europe to vie with each other in producing wares displaying virtuosity unhampered by questions of taste; for example, from as far afield as St. Petersburg, theretofore outside the mainstream of European development, came some particularly colossal and hideous vases in a debased Neoclassical style—which were described by a contemporary writer as "second to few of the productions of Dresden and Sèvres for beauty of outline and perfection of finish."

The degeneration of taste

Those who bought these wares—as well as those who produced them—contributed to the degeneration of taste. Before the advent of mass communications in the 20th century, new fashions originated in the wealthiest stratum of society (which was usually also the most cultivated) and filtered downward. As a result of the political and economic effects of the Seven Years' War (1756–63), combined with the beginning of the Industrial Revolution, the European bourgeoisie prospered, and their wealth enabled them to become patrons and arbiters of taste. Primarily interested in the arts as a means of display or as status symbols, they demanded an excess of intricate and expensive ornament. In East Asia the same process of degeneration began at the same time, at least partly as a result of the large number of export orders received. This pernicious influence was kept at bay for awhile by the emperor Ch'ien-lung, who stigmatized the English as cultural barbarians, but became more pronounced in the 19th century. Similar tendencies may be seen in Japanese pottery after 1853, when many factories worked almost entirely in styles demanded by their customers in the West.

Britain. *Porcelain.* The Neoclassical style, which had been popular during the middle years of the 18th century, gradually lost its earlier simplicity. In France, the rise of Napoleon brought in its train the ostentatious Empire style (copied, for the most part, from the decorative art of imperial Rome), which had much influence in England during the Regency period (1811–20). It is noticeable on the porcelain vases made at such factories as Worcester, Derby, and Rockingham. They were often decorated with well-painted topographical subjects that were no longer confined by frames but ran around the vase as a continuous landscape. Flower painting was often of excellent quality and was much influenced by the work of William Billingsley, a flower painter who worked at Derby toward the end of the 18th century.

At Worcester a factory established by Robert Chamberlain in 1786 produced porcelain decorated in a debased Japanese style. Because of their gaudy colour—iron red and underglaze blue coupled with lavish gilding—some Japan patterns are called thunder-and-lightning patterns. Similar Japan patterns were being employed at Derby and at an older Worcester factory, although much of the work of the latter was more restrained. Some of the best painting at the old factory was executed by Thomas Baxter, who used marine shells as a subject.

It has been said, unfairly, that Josiah Wedgwood, by developing the factory system, was largely responsible for the degradation of the pottery art; Wedgwood wares have usually been in good taste even if they have not always been particularly adventurous. A far more malign influence was that of John Rose of Coalport (Salop). Rose admired the work of Sèvres and imitated it, buying or borrowing specimens to copy and using such ground colours as the *rose Pompadour*. He was one of the first English exponents of the revived Rococo style, which appeared about 1825, and made much porcelain encrusted with applied flowers. His work has been erroneously regarded as a close copy of old Sèvres. Coalport flower painting, however, is very fine in quality and much in the style of Billingsley, who actually worked at the factory for some years.

Spode and Minton

Josiah Spode II, who with his father invented the standard English bone china about 1800, at first made good use of it. Some of his later wares, however, became increasingly pretentious copies of French styles, with highly coloured grounds, lavish gilding, and an excess of applied ornament. In about 1813 William T. Copeland became a partner in the firm, and in 1847 his son, William T. Copeland, Jr., took sole charge of it. In 1970 the company name became Spode, Ltd.

The firm of Minton's was founded at Stoke-upon-Trent in 1793 by Thomas Minton, a Caughley engraver said to have devised for Spode the Broseley Blue Dragon and Willow patterns that are still in use. Like Coalport, the factory was much occupied in copying the work of Sèvres. From 1848 to 1895 they employed a Frenchman, Joseph-François-Léon Arnoux, as art director, and under his tutelage French artists were brought to England; for example, the sculptor Albert Carrier-Belleuse and also Marc-Louis Solon, who was responsible for introducing *pâte-sur-pâte* decoration into England (see below *The European continent*).

The Derby tradition of fine painting was carried into the 19th century, during which time the flower designs became somewhat overblown, although landscapes remained on a high level. The sets of so-called Campaña vases (more properly Campagna), distantly derived from Italianate copies of the Greek krater, were often decorated with landscapes by the brothers Robert and John Brewer and others. The Brewers were pupils of the topographical painter Paul Sandby.

About 1840 Parian ware, an imitation of Sèvres biscuit porcelain, was introduced by Copeland & Garrett (formerly Spode), and a great many figures, some of them extremely large, were made in this medium. Most of them are either sentimental subjects or quasierotic nudes, which were popular subjects of Victorian art. Parian ware had

some success in America, where it was manufactured by Norton and Fenton.

Stoneware and earthenware. Production of earthenware and stoneware for the cheaper market continued on an ever-increasing scale. Lustre decoration, which had been revived in the preceding century, was used more frequently than before. A type of stoneware obviously inspired by Wedgwood's jasperware was made at Castleford, Yorkshire. Ironstone china, a type of opaque stoneware sometimes called opaque porcelain, was introduced early in the 19th century. Pseudo-Chinese and Japan patterns were frequently used to decorate it.

Ironstone china

By 1830 new underglaze colours had been pressed into service for transfer printing. These new colours were particularly used by Ridgway & Co. of Hanley, Staffordshire. Transfer-printed earthenware in blue, which became increasingly popular after 1810, was soon being produced in enormous quantities. It was much used by Spode, who often employed American subjects for wares exported to the United States. Polychrome transfer printing, essayed tentatively at Liverpool during the 1760s, was also mastered.

Earthenware figures were made in large quantities in Staffordshire and elsewhere, the best associated with Enoch Wood. They were intended as chimney ornaments, and the subjects range from bullbaiting to sentimental shepherdesses. Many of them are copied more or less directly from Derby porcelain figures, and they are a sad but accurate reflection of the times during which they were made.

The Great Exhibition of 1851 completed the degeneration started by the revival of the Rococo style. Technical progress allowed the manufacturers ever-increasing elaborations with which they bludgeoned the few remaining sensibilities of their customers. Past styles were indiscriminately and ignorantly copied. Minton's, for example, made an earthenware decorated with coloured glazes that they miscalled maiolica. It was used not only for decorative wares but for domestic articles—such as umbrella stands—and for architectural purposes.

The Paris exhibitions of 1867 and 1878 brought Japanese pottery and porcelain once more to the attention of European manufacturers, but it was not the superb porcelain of Arita that had had so much influence in the previous century. This time the Japanese exported cream-coloured earthenware with a closely crackled surface and lavish painting of poor quality, judging that it would appeal to Western taste. It became extremely popular under the name of Satsuma and was copied avidly at Worcester and elsewhere (see below *Japan: 19th and 20th centuries*).

By 1860 a few people had become profoundly disturbed by the level to which popular taste had sunk. Among them was the English poet and designer William Morris, who founded a firm of interior decorators and manufacturers in 1861. One of his pupils, William de Morgan, started a pottery at Fulham (London) in 1888 that made dishes and tiles inspired by Persian, Hispano-Moresque, and Italian wares. De Morgan used brilliant blues and greens and a coppery red lustre. His designs are a great improvement on those of the factories, although they, too, are derivative.

After about 1860 Doultons of Lambeth (London) copied 18th-century brown stoneware, making small figures and repeating earlier designs. The incised decoration by Hannah Barlow is both pleasant and competent. From a Fulham pottery owned by the Martin brothers came grotesque and often amusing stoneware vases that were sometimes decorated with coloured slips.

Meissen and Sèvres in the 19th century

The European continent. In the 19th century Meissen and Sèvres continued to be the two principal factories and leaders of fashion, although at both places, as elsewhere, artistic standards declined considerably.

In the first half of the 19th century Meissen adopted the revived Rococo style, and a large export trade with England was renewed. This was the period of the sentimental Dresden shepherdess, formerly much admired in England and the United States. Later productions include large and ornate candelabra, overdecorated mirror frames, clock cases, and the like, as well as vases and tureens based on the old Rococo models.

From about 1870, styles altered somewhat and are afterward referred to as those of *die Neuzeit* ("the New Period"). Some of the figures and groups illustrating contemporary subjects throw an amusing sidelight on manners and customs of the time.

At Sèvres, as a result of Napoleon's campaign in Egypt and the newly aroused interest in that country, the Empire style of the first decades of the 19th century incorporated many Egyptian motifs, which were somewhat incongruously translated into porcelain. Also produced were many porcelain plaques with minutely detailed overglaze painting in imitation of easel pictures.

Technical improvements include the introduction, about 1855, of *pâte-sur-pâte,* a process later popular in England, particularly at Minton's. The design was painted in white slip onto a surface of coloured, lightly fired clay. After each coat of slip dried, another was superimposed upon it, until the desired degree of relief had been attained. Finally, it was scraped, smoothed, and incised by metal tools, and the whole object was glazed and fired.

The sculptor Auguste Rodin was employed at Sèvres for a short time but does not seem to have left any enduring marks of his presence. Artistically speaking, Sèvres porcelain has not been very distinguished since the 18th century.

Royal Copenhagen

The Royal Porcelain works at Copenhagen has made a great deal of porcelain with simple patterns in underglaze blue derived from Chinese sources by way of Meissen. Molded fluted shapes are characteristic. Production of the well-known biscuit figures after the sculptor Bertel Thorvaldsen (1768–1844) began in 1867. The factory later introduced a slightly amber-coloured biscuit that was used for figure modelling. Painting on a grayish-toned crackled glaze led to experiments with celadons since, technically, the two have much in common. Other glazes inspired by early Chinese work followed. The firm of Bing and Gröndahl was established in 1853 and has done excellent and imaginative work.

The United States. Although Andrew Duché had succeeded in making porcelain as early as 1741, the first man to produce porcelain in any quantity was William Ellis Tucker of Philadelphia. At first he was a decorator of whiteware, but he started to manufacture both creamware and bone china about 1826. Judge Joseph Hemphill became a partner in 1832, and workmen were imported from Europe. Copies of Sèvres porcelain and other European wares were made about this time in a fine white porcelain body. The first factory at Bennington, Vermont, founded by Capt. John Norton in 1793, made domestic wares, including salt-glazed stoneware. The factory was removed to Bennington Village by his son, Judge Luman Norton, in 1831, and creamware and a brown-glazed ware were produced. In 1839 the factory became Norton and Fenton, and about 1845 the manufacture of Parian ware began. This unglazed near-white porcelain named after Parian marble had been made first in England by Copeland & Garrett (see above *Britain*). John Harrison of Copeland's was hired by Norton and Fenton and brought with him a number of molds. An ironstone china called graniteware or white granite was also made.

Rockingham and yellow-glazed ware

The East Liverpool, Ohio, industry was established in 1838 by James Bennett, an English potter. The first products made there were Rockingham and yellow-glazed ware. In the decade following the Civil War, William Bloor, Isaac W. Knowles, and others introduced the production of whiteware. By the last decade of the 19th century, production had grown until it was the largest pottery-producing area in the world.

At about the same time, Zanesville, Ohio, was also developing as a pottery centre. First production was salt-glazed and slip-decorated stoneware. At a later date much artware was produced in Zanesville plants operated by Samuel Weller, J.B. Owens, George Young, and others. This artware established the basis for a sizable modern interest in collecting. Another important centre during the 19th century was at Trenton, New Jersey, where the first factory was established in 1852. Connected with it was William Bloor, who had some responsibility for putting the industry on a successful footing in East Liverpool. Trenton, like East Liverpool, produced fine, skillfully decorated whiteware.

A close study of the technical side of manufacture was

Study of pottery manufacture at universities

not undertaken until Edward Orton, Jr., succeeded in getting support for the establishment of a department of ceramics at Ohio State University in Columbus in 1894. The New York State College of Ceramics at Alfred, New York, was started soon afterward, with Charles F. Binns as its director. Binns was a member of an English family connected with the manufacture of porcelain at Worcester and Derby during the 19th century and had himself held a supervisory position at Worcester. Similar departments were added to other universities soon afterward, and in 1898 Orton took the lead in forming the American Ceramic Society. In this way knowledge was put on a more scientific basis, and the trained potters who soon became available to the industry were responsible for many technical improvements. Nevertheless, the artistic direction of the factories did not reach a high standard.

Toward the end of the century it became fashionable for American women to study the art of painting on European pottery, and the Cincinnati Art Pottery Company was founded in 1879 to promote sound pottery design. As a result of its work, the Rookwood Pottery was established in 1880 by Maria Longworth Storer. Rookwood wares show a distinct Japanese influence and have excellent red and yellowish-brown glazes (Figure 132).

20TH CENTURY

Pottery factories. At the beginning of the 20th century the Wedgwood factory, whose work has always remained at a high level, extended its already considerable business in the United States, and a service of nearly 1,300 pieces was supplied to the White House during the presidency of Theodore Roosevelt (1901–09). In 1940 the factory began to move to its present site at Barlaston, Staffordshire, after which the historic site at Etruria, Staffordshire, was progressively abandoned.

Designs of Dorothy Doughty

The designs of Dorothy Doughty for the Worcester Royal Porcelain Company, in England, and those of Edward Marshall Boehm, at Trenton, New Jersey, established a new development in decorative porcelain. Characteristic of this kind of work are the American birds of Dorothy Doughty issued in limited editions by the Worcester Company. They are especially remarkable for technical advances in preparing the article for firing, which allow the material to be treated with much greater freedom than hitherto. Porcelain becomes very soft when it reaches the point of vitrification, but, using an elaborate series of props to support free-floating parts, the Worcester technicians succeeded in firing designs that would have been completely impossible earlier. Associated with these models are exact reproductions of natural flowers that also excel in complexity and verisimilitude anything made in the past.

In the early part of the 20th century, Bernard Moore experimented with Chinese glazes (see below *China: Ch'ing dynasty*). He produced some successful flambé and *sang-de-boeuf* glazes on a stoneware body at his small factory in Stoke-upon-Trent. He worked in association with William Burton of Pilkington pottery in Manchester, which made experimental decorative ware of all kinds.

After World War I, figure modelling worthy of the old Meissen tradition was done by Paul Scheurich, Max Esser, Paul Börner, and others. The early red stoneware was also revived. This renaissance was halted temporarily by World War II, but production was resumed by 1950. The wares exported from the German Democratic Republic into western Europe were excellent in quality.

A factory that has preserved its traditional reputation for fine porcelain is Nymphenburg, at Munich, now the Staatliche Porzellan-Manufaktur Nymphenburg. At the beginning of the 20th century it began to use a wider range of underglaze colours with the aid of colour chemists from Sèvres and, about the same time, reissued some of the old figures and services of Bustelli and Auliczek (appropriately marked). Attention was soon turned to services of fine quality in the modern idiom, and excellent figures by Resl Lechner and others were produced. Lechner succeeded in adapting the 18th-century styles to 20th-century purposes in a manner that is an object lesson to those manufacturers who insist, even today, on adding the scrolls and flourishes of the Rococo.

Such factories as Rörstrand and Gustavsberg in Sweden and Arabia Oy in Finland have achieved a growing reputation for excellent design in the modern idiom (Figure 133). The emphasis on form in present-day pottery is to a great extent due to the import of Chinese wares of the Sung dynasty (see below) during the 1920s.

The pottery of the United States bears comparison with that of any other country, and standards are constantly improving. Technically, the United States is perhaps ahead of much of the rest of the world. The growing appreciation of good pottery design has led the national government, as well as state and local governments, to sponsor pottery making as an art. There is also a pottery experimental station in the Tennessee Valley.

Government-sponsored pottery making

The artist-potter. The artist-potter has had an important influence on modern design from the time that Bernard Leach (1887–1979) established the Leach Pottery in St. Ives, Cornwall, in 1920. Leach spent many of his early years in the Far East and learned the art of making *raku* and stoneware in Japan (see below *Japan: Azuchi-Momoyama period*). He began working at a time when

interest in early Chinese wares had greatly increased, and much of his work is obviously influenced by the work of Tz'u-chou (see below *China: Sung dynasty*), as well as that of Japan. It is, nevertheless, strongly individual. One of Leach's pupils, Michael Cardew, has done good work in stoneware, which he often decorated with vigorous patterns drawn with a pleasing economy of outline (Figure 134). William Staite Murray, at one time the head of

the ceramic department of the Royal College of Art, has made some important and interesting stoneware and has influenced many younger potters. Excellent work has been done by continental potters working in England, among them Lucie Rie from Vienna and Hans Coper from Germany. Amusing figures have come from Marion Morris, who was trained in Budapest.

The artist-potters on the Continent tend to be less conservative than their English counterparts, and many new and interesting developments have occurred. Abstraction is particularly favourable to development, since the potter understood its principles long before the 20th-century painters and sculptors came to it. By the 1970s many art schools included pottery making in their curriculum, and students were increasing in numbers.

Somewhat outside the mainstream of pottery tradition, and a markedly individual production related to their work in other media, is the pottery of such well-known artists as Pierre-Auguste Renoir, Paul Gauguin, Joan Miró, Henri Matisse, Ernst Barlach, and Pablo Picasso. A good many of these wares are unique, although some have been repeated by factory production methods.

East Asian and Southeast Asian pottery

CHINA

Nowhere in the world has pottery assumed such importance as in China, and the influence of Chinese porcelain on later European pottery has been profound.

It is difficult to give much practical assistance on the question of Chinese marks. Most of the Chinese marks give the name of the dynasty and that of the emperor; however, many of them have been used so inconsequentially that, unless the period can also be assigned with reasonable certainty by other means, it is better to disregard them. The dating of Chinese pottery is further complicated by the fact that there were traditional and persisting types that overlapped; quite often, therefore, dynastic labels cannot be regarded as anything more than an indication of the affinities of the particular object under discussion.

Chinese symbolic decoration

Chinese decoration is usually symbolic and often exploits the double meaning of certain words; for instance, the Chinese word for bat, *fu,* also means "happiness." Five bats represent the Five Blessings—longevity, wealth, serenity, virtue, and an easy death. Longevity is symbolized by such things as the stork, the pine, and the tortoise, the *ling chih* fungus, and the bamboo, all reputed to enjoy long life. The character *shou,* which also denotes longevity, is used in a variety of ornamental forms. Together, the peach and the bat represent *fu-shou,* long life and happiness. The "Buddha's hand" citron, a fruit with fingerlike appendages, is a symbol of wealth, and each month and season is represented by a flower or plant. The *pa kua,* consisting of eight sets of three lines, broken and unbroken in different combinations, represent natural forces. They are often seen in conjunction with the Yin-Yang symbol, which represents the female-male principle, and which has been well described by the pottery scholar R.L. Hobson as resembling "two tadpoles interlocked." The dragon generally is a mild and beneficent creature. It is a symbol of the emperor, just as the phoenix-like creature (*feng-huang*) symbolizes the empress.

There are three principal religious systems in China: Confucianism, Taoism, and Buddhism. Taoist figures, in particular, appear frequently on porcelain as decoration. The most important, Lao-tzu, has a large and protuberant forehead. He is usually accompanied by the "eight immortals" (*pa hsien*), and these are sometimes modelled as sets of figures. The eight horses of the emperor Mu Wang (Chou dynasty) are also frequently represented. The Buddhist goddess Kuan-yin and the 18 lohan, disciples of Buddha, were also modelled. The "eight Buddhist emblems" appear fairly frequently, as do the "eight precious things" and a collection of instruments and implements used in the arts and known as the "hundred antiques." The "lions of Buddha" (often miscalled dogs) are frequently represented, as is the kylin (properly *ch'i-lin*), which is a composite animal, not unlike a unicorn, that has a fierce appearance but gentle disposition.

Most of these symbols were not used in pottery decoration before the Ming dynasty, although both the dragon and a phoenix-like creature (probably the Chinese pheasant), as well as some floral motifs, are earlier. The *lei-wen,* however, which resembles the Greek key fret (an ornament consisting of small, straight bars intersecting one another in right angles) and is sometimes used on the later ceramic wares, appears on bronzes as early as the Shang and Chou dynasties, where it is called the cloud-and-thunder fret. The *t'ao-t'ieh,* which is a grotesque mask of uncertain origin, also appears on early bronzes and on later pottery and porcelain. Decorations based on Chinese literary sources are usually extremely difficult to trace to their origin.

Earliest Chinese pottery

The earliest Chinese pottery is of the Neolithic period and has been discovered in the provinces of Honan and Kansu. Perhaps the best known of these wares is a series of large urns of red polished pottery with geometric decoration found in the Pan-shan cemetery and at Mach'ang, both in Kansu Province. These were made by hand, the latest specimens with perhaps some assistance from a slow wheel, and are at least as early as 2000 BC.

The only known complete specimen of a fine white stoneware dating from *c.* 1400 BC (Freer Gallery of Art, Washington, D.C.) is decorated with chevrons (linked V-shapes) and a key-fret pattern, the shoulder motifs being reminiscent of those seen on contemporary bronze vessels. This ware is much better in quality than most other surviving pottery of the Shang period (18th to 12th century BC) or of the following Chou dynasty (1111–255 BC). Much Chou pottery is decorated with rudimentary incised ornament, some of which resembles the impress of coarse textiles referred to as mat markings. The shapes used for these pieces were often inspired by bronze vessels.

The development of glazing in China may have started with the application of glass paste to some of the later Chou wares. Stoneware vessels of about the 3rd century BC have a glaze that is little more than a smear but one that has obviously been deliberately applied. This type persisted for several centuries.

The first pottery to survive in appreciable quantities belongs to the Han dynasty (206 BC–AD 220); most of it has been excavated from graves. Perhaps the commonest form is the *hu*, a baluster-shaped vase copied from bronze vessels of the same name and sometimes decorated with relief ornament in friezes taken directly from a bronze original. The hill jar, which has a cover molded to represent the Taoist "Isles of the Blest," is another fairly frequent form, and many models of servants, domestic animals, buildings, wellheads, dovecots, and the like also have been discovered in graves. Some of this pottery is unglazed or decorated with cold (*i.e.*, unfired) pigments, but much of it is covered with a glaze that varies from copper green to yellowish brown; often the colours have become iridescent from long burial. The body is usually a dark red and approaches stoneware in hardness.

Han glaze is more glasslike than that of the Chou period and is of an excellent quality. It contains lead and was frequently coloured green with copper oxide.

Celadon glazes

Yüeh *yao* ("Yüeh ware") was first made at Yüeh-chou, Chekiang Province, during the Han dynasty, although all surviving specimens are later, most belonging to the Six Dynasties (AD 222–589). They have a stoneware body and an olive or brownish-green glaze and belong to the family of celadons, a term that looms large in any discussion of early Chinese wares. It is applied to glazes ranging from the olive of Yüeh to the deep green of later varieties. These colours were the result of a wash of slip containing a high proportion of iron that was put over the body before glazing. The iron interacted with the glaze during firing and coloured it.

T'ang dynasty (AD 618–907). Chinese pottery reaches an important stage in its development during the T'ang dynasty.

Nearly everything that has survived has been excavated from tombs, many of them found accidentally by railway engineers and latterly by more systematic excavations. Excavations at Sāmarrā' on the Tigris, a luxurious residence built by the caliph al-Muʿtaṣim (son of Hārūn ar-Rashīd) in AD 836 and abandoned in 873, have uncovered many fragments of T'ang wares of all kinds. Perhaps the most important finds from a historical viewpoint are the fragments of what is undoubtedly porcelain. An Islāmic record of travels in the Far East, written in 851, records "vessels of clay as transparent as glass." There can be little doubt, therefore, that translucent porcelain was made in the T'ang period, although it was not until the Yüan dynasty (1206–1368) that it began to resemble the type with which the West is most familiar.

Early porcelain

Perhaps the most important single development was the use of coloured glazes—as monochromes or splashed and dappled. The T'ang wares commonest in Western collections are those with either monochrome or dappled glazes covering a highly absorbent, buff, earthenware body. The dappled glazes were usually applied with a sponge, and they include blue, dark blue, green, yellow, orange, straw, and brown colours. These glazes normally exhibit a fine crackle and often fall short of the base in an uneven wavy line, the unglazed surface area varying from about one-third to two-thirds of the vessel.

Dappled glazes are also found on the magnificent series of tomb figures with which this period is particularly associated (Figure 135). Similar figures were made in unglazed earthenware and were sometimes decorated with cold pigment. Although the unglazed specimen or those covered only with the straw-coloured glaze are occasionally modelled superbly, many are crude and apparently made for the tombs of the less affluent and influential. Most of the glazed figures are much better in quality and occasionally reach a large size; figures of the Bactrian camel, for instance, are particularly impressive, some being nearly three feet high. The Bactrian pony, introduced into China about 138 BC, is to be found in many spirited poses. This fashion for tomb figures fell into disuse at the beginning of the Sung dynasty (AD 960–1279) but was revived for a short while during the Ming period (1368–1644), when T'ang influence is noticeable.

Marbled wares are seen occasionally. The effect was achieved either by combing slips of contrasting colours (*i.e.*, mingling the slips after they had been put on the pot, by means of a comb) or by mingling differently coloured clays. Another type of T'ang ware (probably from Honan) had a stoneware body with a dark-brown glaze streaked by pale blue. Most vessels stand on a flat base; although later T'ang wares sometimes were given a foot ring, for the most part this can be regarded as evidence in favour of a Sung dating.

Sung dynasty (AD 960–1279). The wares of the Sung dynasty are particularly noted for brilliant feldspathic glazes over a stoneware body and their emphasis on simplicity of form. Decoration is infrequent but may be incised, molded, impressed, or carved; a certain amount of painted decoration was done at Tz'u-chou in Chihli

(now called Hopeh) Province (see below). The esteem accorded to the Sung wares accounts for the relatively large number that have survived. The principal varieties are Ju, *kuan,* Ko, Ting, Lung-ch'üan, Chün, Chien, Tz'u-chou, and *ying-ch'ing.*

Ju ware has a buff stoneware body and is covered with a dense greenish-blue glaze that sometimes has a fine crackle. It was made in Honan at an Imperial factory that apparently had a life of about 20 years, starting in 1107.

Kuan ("official") is another Imperial ware that is also exceedingly scarce. It was probably first made in the north, the kilns being reestablished at Hangchow in Chekiang Province about 1127, when the court fled southward to escape the Chin Tatar invaders. The body is of stoneware washed with brown slip. The glaze varies from pale green to lavender blue, with a wide-meshed crackle emphasized by the application of brown pigment. Chinese references to "a brown mouth and an iron foot" can be identified with the colour of the rim and the foot ring.

Ko ware is closely related to *kuan* ware. It has a dark stoneware body and a grayish-white glaze with a well-marked crackle, which was induced deliberately for its decorative effect.

Ting wares are white. Some exhibit an orange translucency (Figure 136), while the coarser varieties are opaque. The finest examples are called "white" (*pai*) Ting. On the exterior of bowls and similar vessels the glaze of white Ting is apt to collect in drops, called teardrops. Many articles, particularly bowls, were fired mouth downward, leaving an unglazed rim that was afterward bound with a band of copper or silver. (Bands appear occasionally on other Sung wares, notably *ying-ch'ing,* and were sometimes used to conceal damage rather than an unglazed rim.) Coarser varieties are known as "flour" (*fen*) Ting and "earthen" (*t'u*) Ting, and there are also a few examples of black Ting. As in the case of *kuan* ware, the kilns are said to have been removed southward in 1127, but it has so far proved impossible to differentiate between the northern and southern varieties. Other white wares made elsewhere during the period include those of Tz'u-chou and a variety covered with a white slip over a grayish body from Chü-lu Hsien (both in present Hopeh Province).

Lung-ch'üan

The celadons of Lung-ch'üan are, perhaps, the most common of the classic Sung wares (Figure 137). The town is in the province of Chekiang, near the capital of the southern Sung emperors at Hangchow. The kilns probably date back to the 10th century. The glaze, of superb quality, is a transparent green in colour. It is thick and viscous, usually with a well-marked crackle. (The glaze on early specimens is less transparent and is denser.) The body is gray to grayish white, best seen at the rim, where the glaze tends to be thin. By far the most frequent surviving examples of Lung-ch'üan celadon are large dishes, for which there was a thriving export trade, due in part to the superstition that a celadon dish would break or change colour if poisoned food were put into it. Bowls and large vases, both of which are scarce, were also made with this glaze. Decoration is usually incised, but molded decoration is also found. On some pots the molding was left unglazed, so that it burned to a dark reddish brown—an effective contrast to the colour of the glaze. The more finely potted wares are the scarcest and often the oldest. The heavier varieties were intended to withstand the rigours of transport to overseas markets, and probably most of them belong to the Yüan dynasty (1206–1368), when the export trade was considerably extended.

By courtesy of the Victoria and Albert Museum, London

Figure 137: Lung-ch'üan celadon ware wine jar and cover, with light bluish-green glaze, Sung dynasty, 12th century. In the Victoria and Albert Museum, London. Height 25.4 cm.

Chün ware comes from the K'ai-feng district of Honan Province. The body is a grayish-white, hard-fired stoneware covered with a thick, dense, lavender-blue glaze often suffused with crimson purple. This is the first example of a reduced copper, or flambé, glaze. Conical bowls are especially numerous, and dishes are not unusual, but the finer specimens are usually flowerpots, sometimes said to have been made for Imperial use. Characteristic are barely perceptible channels or tracks caused by the parting of the viscous glaze; these are called earthworm tracks by the Chinese. The kilns probably continued to produce this ware until the 16th century, and it is difficult to separate some of the later productions from the earlier.

Chien ware is called after the original place of manufacture, Chien-an, in Fukien Province. Manufacture was later moved to nearby Chien-yang, probably during the Yüan period. The glaze is very dark brown, approaching black, over a dark stoneware body, and it usually stops short of the base in a thick treacly roll.

There are many variations in the colour of the glaze. Streaks in lighter brown are referred to by the Chinese as hare's fur. Silvery spots on the glaze are called oil spots. The most usual surviving form is the teabowl; these were much esteemed by the Japanese under the name of *temmoku* and were used in the tea ceremony (see below *Japan: Kamakura and Muromachi periods*).

Tz'u-chou ware

The kilns of Tz'u-chou, formerly in Honan, are now in Hopeh Province. The earliest surviving examples are referable to the T'ang dynasty. In the Sung period, vases, wine jars, and pillows (which are more comfortable than they appear) were the most usual products. The body is usually a hard-fired, grayish-white stoneware that was first covered with a wash of white slip and then with a transparent glaze. For the first time painted decoration appears under the glaze, perhaps as a result of influence from the Middle East (see above *Islāmic: Mesopotamia and Persia: 11th to 15th century*). Decoration is nearly always in brown or black; the motifs are usually floral and display a singular freedom of line that is very attractive. (The inclusion of human and animal figures suggests a Yüan or a Ming dating, at the least.) The slip covering was sometimes carved away, leaving a pattern in contrasting colour, a technique also used in conjunction with a dark brown glaze. A hare's-fur glaze, similar to that of Chien wares, was also employed. A blue glaze with painted decoration in black beneath it was obviously inspired by contemporary Persian pottery decorated in the same way. Another innovation, perhaps derived from the same source, is the use of colours applied over the glaze. These are limited to primitive reds and greens and yellows.

An important and not uncommon ware is *ying-ch'ing* ("shadowy blue"). It was manufactured in both the south (Kiangsi) and the north (Hopeh). Moreover, it was extensively exported and has been found as far west as the ruins of al-Fusṭāṭ in Old Cairo. The body is pale buff in colour, usually translucent, and thinly potted, breaking with a sugary fracture. Most genuine examples seem to belong to the Sung and Yüan periods, but it is probable that, in the north at any rate, manufacture started late in the T'ang

dynasty and lasted well into the Ming period. Bowls of conical form are the commonest survival, and many are decorated with incised floral and foliate motifs. Lightly molded decoration occurs, as does combing of the clay. The *mei p'ing* vase is found with this glaze; it has a tall body with straight sides, high, rounded shoulders, and a short narrow neck and was intended to hold a single spray of prunus blossom. Stem cups, deep bowls, and ewers were also produced. Bowls sometimes have the rim bound with copper.

Yüan dynasty (1206–1368). The Yüan, or Mongol, dynasty is often regarded as being no more than transitional between Sung and Ming types. This is not entirely true. Undoubtedly, many Sung types were continued, just as the T'ang types were continued at the beginning of the Sung dynasty, but there are other wares that represent a new departure. The manufacturing centre of Ching-te-chen increased in importance and first manufactured the white translucent porcelain that was to have a revolutionary effect on Chinese wares. The use of painted decoration, begun during the Sung period at Tz'u-chou, also became much more widespread, and the two techniques were combined in a manner that later affected the course of porcelain manufacture throughout the world.

The *Ko ku yao lun* of 1387 refers to *shu fu* ware, a type of white porcelain. The base is unglazed. Decoration in relief, painted in slip or engraved, is to be seen on some surviving examples of porcelain. It appears to be a development of the earlier *Ting ch'ing*. Much more unusual is the appearance of a few specimens of Yüan date that are painted with reduced copper red under the glaze. As mentioned above, the potters of Chün-chou had achieved this colour, but only in the glaze.

The use of underglaze blue was introduced from the Middle East, where it had been employed at least as early as the 9th century, specimens thus decorated having been recovered at Sāmarrā' (see below *Islāmic pottery: 'Abbāsid*). The best known example of Yüan porcelain decorated in this manner, which is usually referred to as blue-and-white, is a pair of vases in the Percival David Foundation of Chinese Art in London. They bear a date equivalent to 1351. The peony scroll, carved or in applied relief, appears on some of these blue-and-white wares.

Blue-and-white ware

Ming dynasty (1368–1644). The Mongol emperor Shun Ti was defeated in a popular uprising, and the Hungwu emperor, founder of the Ming dynasty, succeeded him in 1368. When the country had recovered from these internecine struggles, pottery art took a new lease of life, though under somewhat changed conditions. The Sung wares went out of favour, and the old factories sank into obscurity, while the fame and importance of the great porcelain town of Ching-te-chen, near the P'o-yang Hu in Kiangsi Province, overshadowed all the rest. The Imperial factory there was rebuilt and reorganized to keep the court supplied with the new porcelain. The staple product of Ching-te-chen was the fine white porcelain that made "china" a household word throughout the world; and as this ware lent itself peculiarly well to painted decoration, the vogue for painted porcelain rapidly replaced the old Sung taste for monochromes.

"China" ware

The reign of the Yung-lo emperor (1402–24) is remarkable for some extremely thin-walled pieces, referred to as "bodiless" (*t'o t'ai*) ware. Engraved examples are known, and Chinese commentaries refer to specimens decorated in red.

After this early period, Ming wares generally are fairly easily recognizable. Porcelain replaced stoneware as the usual medium, and polychrome decoration became widely employed. The largest single group of Ming porcelain is that painted in blue underglaze (Figure 138). Much of the pigment used was imported from Middle Eastern sources. Supplies of this so-called Mohammedan blue (*hui-hui ch'ing*), which came from the Kashān district of Persia, were not always obtainable and were interrupted on more than one occasion. The quality of the blue-painted wares, however, remained to a great extent dependent on its use until the end of the 16th century, when methods of refining native cobalt were devised.

The wares lack much of the precision of the porcelain made during the following Ch'ing period (1644–1911/12), when a kind of factory system grew up that divided the work into a large number of repetitive operations. Little trouble was taken to smooth over imperfections of manufacture, and foot rings are often finished summarily. The glaze, too, frequently has minor defects, and articles, such as vases, are sometimes slightly distorted and carelessly finished. The shape of many examples can fairly be described as massive, in spite of the fact that most of them were made for export, and the difficulties of transporting them must have been considerable. None of these factors evinces a lack of skill, especially as the potters were quite capable of technical virtuosity when they wished to display it—some of the most thinly potted of all Chinese porcelain belongs to this period. It seems that the Ming potters disdained the attitude of mind that treated blemishes as important; occasional distortions, in fact, were regarded as lending interest to an object. The Chinese did not carry this aesthetic creed to the same lengths as the Japanese (see below *Japan*), but the difference seems to be largely one of degree. Ming wares can fairly be described as masculine, in contrast to the more feminine, more precisely finished wares of the later Ch'ing period.

Reign of the Hsüan-te emperor (1425–35). In this period the arts were particularly fostered and a high level of achievement attained. The blue painting is blackish in colour, with dark spots at intervals where thick blobs of pigment were deposited by the brush—the so-called heaped and piled effect. The motifs are floral and foliate, with the occasional use of fish and waterfowl. Sometimes vessels are bordered by a pattern of conventional rock amid waves—the Isles of Immortality—often referred to as the Rock of Ages pattern. The pattern appears frequently throughout the Ming period and later.

Heaped and piled effect

Contemporary Chinese commentaries refer to the use of underglaze copper red—often called sacrificial red for uncertain reasons. To a great extent sacrificial red was abandoned later in the dynasty in favour of overglaze iron red, although it was used again during the reign of the Ch'ing dynasty K'ang-hsi (1661–1722) and Yung-cheng (1722–35) emperors and appears in a rather primitive form from some provincial kilns. Both copper red and blue were used as monochromes and, occasionally, together; but since these pigments required a slightly different firing temperature, one or the other is usually deficient in quality.

The use of overglaze colours was rare, and the technique had by no means been fully mastered.

Reign of the Ch'eng-hua emperor (1464–87). Much

Figure 138: Flask decorated with a dragon and wave scrolls in underglaze blue, Ming dynasty, 14th century. In the Victoria and Albert Museum, London. Height 36.8 cm.

overglaze decoration can be attributed with a reasonable measure of certainty to the reign of Ch'eng-hua, the finest examples being, perhaps, the chicken cups, so-called because they are decorated with chickens. Their decoration is outlined in underglaze blue and filled in with soft overglaze colours called "contending colours" (*tou ts'ai*). Ch'eng-hua overglaze colours were thin, subdued in colour, and pictorial in effect.

The practice of enamelling directly onto unglazed, or biscuit, porcelain instead of onto a glazed and fired body is sometimes thought to have begun in this reign, though that of the Chia-ching emperor (1521–67) is the more likely. Ming specimens are, in any case, extremely rare; most belong to the reign of the K'ang-hsi emperor (1661–1722) in the Ch'ing dynasty.

Reigns of the Hung-chih and Cheng-te emperors (1487–1521). The first use of a coloured overglaze ground can be attributed to the reign of the Hung-chih emperor (1487–1505), when a yellow of variable shade first appears. In the reign of the Cheng-te emperor (1505–21) the influence of the Muslim palace eunuchs who supervised the Imperial kilns is seen in such blue-and-white motifs as the Mohammedan scroll, which is composed of somewhat formal flowers joined by S-shaped stems, with scroll-like leaves at intervals along them. Mohammedan blue was again available. The earliest versions of this theme, which seems orginally to have come from a textile pattern, are the least stiffly drawn. The linear style of painting characteristic of earlier porcelain altered to one in which outlines were filled in with flat ungraduated washes.

Muslim influence

Reign of the Chia-ching emperor (1521–67). This reign is notable for a deterioration in the quality of the porcelain body, offset by the use of rich dark blue. Wares painted overglaze, too, were executed in good colours, with well-marked outlines. A characteristic colour, the opaque iron red (*fan hung*), sometimes called tomato red, was used as a monochrome with gilt traceries over it on bowls that sometimes had interior decoration in underglaze blue. Various wares have decoration in red and green, a palette that became more familiar later. A yellow glaze is found in conjunction with incised decoration (usually a dragon) in green. Very rarely was a green or blue monochrome used.

Reigns of the Lung-ch'ing and Wan-li emperors (1567–1620). The styles of Chia-ching were, to some extent, continued in the following reigns of the Lung-ch'ing (1567–72) and Wan li (1572–1620) emperors. A palette containing underglaze blue in conjunction with green, yellow, aubergine purple, and iron red (the precursor of the later Ch'ing *famille verte* palette) was known as "Wan-li five-colour" ware (Wan-li *wu ts'ai*). The red and green Chia-ching decoration was also used, and vast quantities of blue-and-white porcelain were produced for export. The body is quite unlike that used earlier in the dynasty, being thin, hard, crisp, and resonant. It is the commonest of all Ming wares in the West. During the reign of the Wan-li emperor, much pierced work (*ling lung*) was done. Pierced objects range from small brush pots to vases with coloured glazes sometimes termed *fa hua*.

The Ming dynasty ended in 1644. The wares of the last three emperors, for the most part, followed styles already established; perhaps an exception can be made for blue-and-white, which shows a number of new departures in both form and decoration. Many of the vases are without a foot-ring and stand on a flat, unglazed base. Forms based on European wares were obviously made for export.

Provincial and export wares. Most of the wares hitherto discussed were made in the Ching-te-chen area; it remains to consider the other wares of the period. The export of celadons went on, not only to the countries west of China but also to Japan, where they were much esteemed. Most celadons attributable to the Ming period have incised under the glaze floral and foliate decoration of a kind that also appears on blue painted wares.

The fine porcelain of Te-hua in Fukien Province was first made, perhaps, in the early part of the dynasty. Most of this porcelain was left undecorated, and received the name in Europe of blanc de chine. The glaze is exceptionally thick and lustrous, and early examples are often slightly ivory in tone. Overglaze painting is infrequent; virtually all early coloured speciments, figures or vessels, have been decorated in Europe, usually in the Netherlands. Figures especially were produced at the Te-hua kilns, with the Buddhist goddess Kuan-yin being a favourite subject.

Blanc de chine porcelain

The stoneware of I-hsing in Kiangsu Province was known in the West as Buccaro, or Boccaro, ware and was copied and imitated at Meissen, at Staffordshire, and in the Netherlands by Ary de Milde and others. Its teapots were much valued in 17th century Europe, where tea was newly introduced. The wares of I-hsing are unglazed, the body varying from red to dark brown. The molding is extremely precise and was often sharpened by grinding on a lapidary's wheel. The body was sometimes polished in the same way.

Most of the Ming stoneware ridge tiles and roof finials were made at kilns near Peking. Many of them are decorated in green, yellow, turquoise, and aubergine-purple glazes, recalling the wares of the T'ang dynasty. A Ming date is exceedingly optimistic for most of them. To this group belong, it is thought, a few large figures that have sometimes been somewhat doubtfully awarded a T'ang date.

The provincial tile kilns also manufactured "three-coloured" (*san ts'ai*) wares, perhaps originally a product of the Tz'u-chou kilns. These were decorated with coloured glazes that were often kept from intermingling by threads of clay (cloisonné technique) or were used in conjunction with the pierced technique (*fa hua*). Others have engraved designs under the glazes. Most existing specimens are large vases, barrel-shaped garden seats, and the like. The best are extremely handsome and imposing, turquoise and dark-blue glazes being particularly effective.

Ch'ing dynasty (1644–1911/12). With the Ch'ing dynasty came the beginning of the immense vogue for porcelain in Europe that was to reach its height during the first half of the 18th century. Many varieties of Ch'ing ware are common in the West. Its wares differ, for the most part, from those of the Ming period in a fairly distinctive manner. Potters had their medium under almost complete control, and their products are much more precisely finished. Their finesse contrasts sharply with the struggles of potters in Europe, where porcelain manufacture did not emerge from the purely empirical stage until the 19th century. Letters written in 1712 and 1722 by a Jesuit missionary who spent some years at Ching-te-chen record that some Ch'ing pieces were handled by as many as 70 men, each contributing a small part to the total effect, and this is one of the reasons why many Ch'ing wares are found to lack the freshness and the spontaneity of Ming decoration.

Difference between Chinese and European pottery making

The Imperial kilns of Ching-te-chen were fortunate in the support they received from the palace during the reigns of the K'ang-hsi (1661–1722), Yung-chen (1722–35), and Ch'ien-lung (1735–96) emperors. The K'ang-hsi emperor, in particular, was a patron of the arts on a considerable scale.

Underglaze blue and red. The blue-painted porcelain of the Ch'ing dynasty has been somewhat neglected in the 20th century. This is probably due to the ridiculously high value placed on it during the latter years of the 19th century, when it was often called Nanking ware. Even the best, which belongs to the reign of the K'ang-hsi emperor, hardly bears comparison with the finer Ming wares, though its influence on European porcelain was far-reaching. Blue-and-white porcelain was exported to Europe in vast quantities, and many of the forms were especially made for export; the condiment ledge on plates and dishes, for instance, which first appeared in the reign of the Wan-li emperor (Ming dynasty), had been added for Western customers (the Chinese used the saucer dish). The blue-and-white of the K'ang-hsi period has an extremely white body, and the blue is exceptionally clear and pure. It is variable in shade, and the design is executed in graduated washes within lightly drawn outlines, a point of difference from Ming wares. Many of the designs of the Ming period were in use, and, of the later patterns, those illustrating literary and historical themes are probably of the highest quality.

Ginger jars decorated with prunus blossom reserved in white on an irregular blue ground, intended to represent

the cracked ice of spring and sometimes described as pulsating, were once valued highly; in the mid-20th century a more realistic attitude was taken toward them.

Underglaze copper red was also used during the 18th century. The stem cups of the Yung-cheng period with three fruit or three fish in silhouette, which imitate those of Hsüan-te, are much better known than the wares they copied. Copper red also appears in conjunction with underglaze blue, and a greenish-toned glaze is common with pieces thus decorated.

Use of powder blue

Underglaze blue was sometimes used as a monochrome ground colour. It was blown on the surface in powder form before glazing; a bamboo tube, closed with gauze at one end, was employed for the purpose. It is thus called powder blue, or, in Chinese, *ch'ui ch'ing* ("blown blue"), and is distinct from the sponged blue grounds of the Ming dynasty. It was subsequently used at several of the porcelain factories in Europe. Clair du lune (*yüeh pai*, "moon white"), a cobalt glaze of the palest blue shade, was also used.

Coloured glazes. Copper red, called oxblood (*sang-de-boeuf*) by the French, appears in monochrome form as Lang *yao*. This glaze was also known to the Chinese as "blown red" (*ch'ui hung*). It was certainly used as a monochrome in early Ming times and possibly even earlier, and is the direct ancestor of the showy *flambé* glazes (*yao pien*) (Figure 139) of the Ch'ien-lung period that are often vividly streaked with unreduced copper blue.

Another variation, no doubt at first accidental, is the glaze known in the West as "peach bloom," a pinkish red mottled with russet spots and tinged with green. The Chinese have various names for it, but perhaps the commonest is "bean red" (*chiang-tou hung*). It is used on a white body. Most objects glazed in this way are small items for the writer's table.

Monochromes of all kinds are a distinct and important section of Ch'ing wares, and many reproductions of Sung monochromes were made. The use of iron as a pigment can be seen in a revival of the celadon glaze. The Ching-te-chen celadons have, generally, a pale-green glaze over white porcelain, the foot-ring being given a wash of brown to simulate the old ware. Meanwhile, celadons of the Lung-ch'üan type were still being made. In addition to the celadon glaze, iron was used to produce colours varying between café au lait and pale yellow and also "deadleaf" brown.

Sometimes panels were reserved in white and painted in overglaze colours. Specimens thus glazed appear in the old Dutch catalogues as Batavian ware, because the wares were imported via the Dutch centre of trade and transshipment at Batavia (modern Djakarta), in Java. They are also related to "mirror black" (*wu chin*), a lustrous colour obtained by the addition of manganese, and sometimes decorated with gilding or even, as in at least one extant specimen, with both gilding and silvering. Imperial yellow, a lead glaze often used over engraved dragons and similar designs, was again employed during the 19th century.

Brilliant turquoise glazes derived from copper have been produced up to the mid-20th century, although later examples seldom have the quality of the earlier ones. The glaze is usually covered with a network of fine crackle, and in some examples there is engraved decoration under the glaze. Related glazes are the copper greens—for example, leaf green and cucumber green, the latter being speckled with a darker colour. Apple green is an overglaze colour used as a ground and applied over a crackled gray glaze. Most greens are relatively late.

Purple, or aubergine, glazes derived from manganese are seen occasionally. Brinjal bowls, decorated with engraved flowers, have an aubergine ground in conjunction with dappled green and yellow glazes. (Brinjal, in fact, means aubergine, or eggplant, which is a favourite food in parts of the East.) Bowls with engraved dragons and a combination of only two of these colours are somewhat better in quality.

Overglaze colours. Overglaze colours were sometimes used as monochromes; for example, iron red or, as it is sometimes called because it varies a little in shade, coral red. The surface is usually glossy but occasionally mat. The rose colour, discussed below, was used both as a monochrome and as a ground colour.

The wares enamelled on biscuit are a much sought after group. They are a development of the Ming *san ts'ai* wares, which were still being made during the Ch'ing period. The effect of painting directly on biscuit was to produce a soft and distinctive colouring that is extremely attractive. The outlines were first painted directly on the unglazed surface in brownish black; some of the colours were then painted within these outlines and others were washed over them; however, red or blue overglaze colours, when they appear, are usually provided with a patch of glaze underneath them. The practice seems hardly to have survived the K'ang-hsi period, except for deliberately made later copies.

Famille verte overglaze

During the reign of the K'ang-hsi emperor the wares decorated overglaze were painted in the *famille verte* palette, usually over a white glaze (Figure 140). The name *famille verte* ("green family") is derived from the distinctive green employed, but the wares are a development of the Wan-li five-colour ware, the major difference being the replacement of the earlier underglaze blue by an overglaze blue. On most genuine examples it is possible to see a distinct halo around the overglaze blue, but its absence does not condemn the piece as not genuine. The *famille noire* has the *verte* palette in conjunction with a black ground; the *famille jaune* uses the same colours, but is used in conjunction with a yellow ground. In each case the white porcelain disappears under the colours.

During the reign of the K'ang-hsi emperor (*c.* 1685) an opaque rose-coloured overglaze appears. This and its related colours were called "foreign colours" (*yang ts'ai*). It soon formed the characteristic colour of a group of wares, referred to as the *famille rose*, which was particularly developed during the reign of the Yung-cheng emperor. It more or less replaced the *verte* palette. The translucent overglaze colours of the earlier period tended to become opaque, and painting has a more feminine quality.

During the 18th century the white wares of Ching-te-chen were made mostly for the home market, though a few were exported. They included examples of the bodiless ware and the *an hua* (literally "secret language"). The latter, copied from a traditional Yung-lo (1402–24) type, has designs lightly incised or painted with white slip. The body

is white, and the whole is covered with clear glaze. The decoration can only be seen plainly if light is allowed to shine through it. Pierced work was revived in certain rare pieces inspired by jade; the use of piercing that was filled with glaze was derived from Persian Gombroon ware.

European influence and the export trade. Before the mid-18th century, some European wares had found their way to China, as witness certain copies of early Meissen porcelain. The taste of the European trader, though hardly representative of the more cultured section of Western civilization, also began to have influence.

Much decoration was done in studios in and around the port of Canton, white porcelain being sent from Ching-te-chen for the purpose. Enormous quantities of *famille rose* porcelain were painted there, including most of the "ruby-backed" dishes, which are completely covered on the reverse, except for the interior of the foot ring, with a ground of overglaze opaque rose. They often have an elaborate arrangement of minutely delineated border patterns around the central subject (usually pretty women), demonstrating the new, and later widespread, idea that the beauty of an object is directly proportional to the amount of decoration on it. This theory was to be one of the causes of the degeneration of later Chinese and Japanese wares; it was, however, by no means confined to the Orient and can be seen in most 19th-century European porcelain.

The Yung-cheng painters were the first to carry foliate decoration over on to the back of the dish, usually as a prolongation of the stem. This was repeated later during the reign of the Tao-kuang emperor (1820–50). The European tendency to draw flowers in a naturalistic manner also appears in China from the Yung-chen period onward, although the practice was not carried to the same lengths.

An attempt to imitate the European method of overglaze painting, in which colours were applied in flat washes that partly sank into soft porcelain glazes, can be seen in the "ancient moon pavilion" (*ku yüeh hsüan*) wares. These will sometimes have a European subject, for example, a Watteau shepherdess, but Chinese subjects were also used.

Oriental Lowestoft

Of the wares more directly due to European intervention perhaps the best known is Chinese export porcelain, still sometimes known as Oriental Lowestoft. The name is due to an error on the part of William Chaffers (the author of a book on pottery marks), who persisted in attributing these wares to the small English factory at Lowestoft. If this porcelain is important at all, it is as a curiosity; the artistic value is nearly always negligible. The styles are usually based on those of European pottery or metalwork or on a combination of Western and Oriental motifs in an unpleasing jumble. The designs were provided by Western traders, and coats of arms are comparatively common.

Other wares connected with the export trade are those decorated with the Mandarin patterns; these came from Cantonese studios and were introduced toward the end of the 18th century. They have figure subjects in panels that are surrounded with coloured grounds and an excess of floral and other ornament in unprepossessing combinations of colours.

Much white porcelain was sent to Canton to be decorated, but much, too, was shipped to Europe for the same purpose. Many examples were painted by German studio painters, by Dutch enamellers, and by English "outside decorators."

Europe, of course, was not the only export market open to the Chinese. Much blue-and-white was exported to the traditional markets in Persia and the Near East (Arabic inscriptions can be seen on some specimens) and elsewhere—India, Thailand, Burma, and Tibet.

Other Chinese kilns

The wares discussed so far have been principally those of Ching-te-chen. Those of Te-hua in Fukien Province, however, are also important. Figures of the Buddhist goddess Kuan-yin in particular were exported in enormous quantities, and the *an hua* and pierced decorations often came from Te-hua. Vessels, such as libation cups with applied prunus sprigs, were copied by European factories in the 18th century, notably by those at Meissen, Chelsea and Bow, and Saint-Cloud. The body is usually white, sometimes with an ivory tone, and the glaze is thick, rich, and lustrous. European forms are to be seen occasionally, and most coloured examples have been decorated in the West. The kilns of I-hsing also continued making the traditional wares.

19th and 20th centuries. The 19th century has little to offer that is new or of good quality. Snuff bottles painted with miniature designs were first made toward the end of the 18th century, but most belong to the reign of the Chia-ch'ing (1796–1820) and Tao-kuang (1820–50) emperors. Bowls with circular medallions painted in overglaze colours with yellow or rose grounds are, perhaps, among the finer wares. Also of good quality are bowls covered with an opaque ground, rose or yellow, with designs engraved into it. These were first made in the 18th century and extend to the reign of the Tao-kuang emperor.

Most of the wares of Tao-kuang are poor in quality, although some examples in the style of Yung-cheng are better. The glaze has a musliny texture similar to that seen on some early Ming wares and on Japanese porcelain from Arita. Translucent overglaze colours over underglaze blue are a Yung-cheng type that had a revival at this time. In addition, the *rose-verte* palette was commonly used.

In 1853 the Taiping Rebellion led to the destruction of the kilns at Ching-te-chen, which were not rebuilt until 1864. The reign of the T'ung-chih emperor (1861–75) is principally notable for poor copies of earlier monochromes, including the peach-bloom glaze. Nearly all wares from this time onward are slick copies of older work.

KOREA

Because Korea lies to the north of China and close to the islands of Japan, it has usually formed a cultural link

between the two countries. During the Japanese invasion of 1592, for instance, many Korean potters were taken to Japan, where they were set to work making tea ceremony wares, which had hitherto been imported, and they later helped to found the porcelain industry.

It is difficult to distinguish some Korean wares from those made in the northern provinces of China during the contemporary Han to T'ang period. The wares of the Silla period (57 BC–AD 935) include some reminiscent of those of the Chou dynasty. Specimens of stoneware obviously based on metalwork are distantly related to some of the Han bronzes. Patterns on these wares are geometric and incised into the clay before firing.

An olive-green glaze was introduced later in the Silla dynasty, probably about the 9th century. Roof tiles and finials have a brown or a green glaze and may be contemporary with the Han dynasty.

The wares of the Koryŏ dynasty (918–1392; roughly corresponding to the Chinese Sung and Yüan dynasties) exhibit a much greater diversity and fall into rather more clearly defined groups. The attribution of certain black-glazed *temmoku* types (see above *China: Sung dynasty*) is controversial, but it seems that at least some of them were made in Korea. Many celadons, too, have typical Korean lobed forms, based on the melon or the gourd. These are also to be seen in porcelain, much of which has a bluish-white glaze. Some lobed boxes, usually circular, are decorated with impressed designs and are probably always Korean.

One of the difficulties in the study of Korean pottery is that practically everything has been recovered from tombs; few actual kiln sites have been discovered. Nevertheless, one such excavation at Yuch'ŏn-ni has disclosed shards of both the celadon glaze and of white porcelain from which it seems evident that white porcelain resembling both the *ying-ch'ing* and Ting types was made (see above *China: Sung dynasty*). The earliest vessels were probably fairly close copies of Chinese styles, while the distinctive Korean style followed rather later. A crazing of the glaze and a certain amount of flaking are characteristic. A mere handful of specimens, some fragmentary, of inlaid white porcelain have survived. They are best represented by a vase in the Natural Museum of Modern Arts in the Tŏksu Palace of Seoul that has panels of black-and-white inlay beneath a celadon glaze. Decoration on much Korean porcelain of the period is either incised (foliage being a frequent motif), combed, or molded in shallow relief.

White porcelain

Korean celadons have a stoneware body covered with a glaze varying from bluish green to a putty colour; some are obviously analogous to the celadons of Yüeh-chou. Characteristic of Korean pots are the stilt or spur marks to be seen on the otherwise glazed base; these are the points on which the pots rested in the kiln. Many of the forms are lobed. Perhaps the most important divergence from the usual Chinese celadon is the presence of inlaid decoration beneath the glaze of many specimens, later examples of which are often referred to as *mishima* (Figure 141).

Mishima decoration

The designs were first incised into the clay, and the incisions were then filled with black and white slip. The inlaid patterns are diverse, but most of the subjects are floral; birds are to be seen occasionally. Isolated flowers with symmetrically radiating petals are also found, principally on boxes.

While most Korean wares of the Yi dynasty (1392–1910) are distinctly rougher than those of China in the Ming and Ch'ing periods, the decoration is often magnificent in quality. Most can be clearly distinguished from Chinese wares by their forms, which show distinct differences in almost every case. Lobed forms suggested by the melon are very characteristic, and the pear-shaped bottle differs in its proportions from that of the Chinese. The large rugged jars with high shoulders are not so precisely potted as similar jars from China, often showing a marked degree of asymmetricality. Twisted rope handles are also peculiar to Korea. Many of the ewers are obvious adaptations from metalwork.

Painting in brownish black beneath a celadon glaze, which had begun in the Koryŏ dynasty, continued in the Yi dynasty. Inlaid decoration was also executed during the early part of this period, the pattern often being engraved by stamps rather than incised freehand. Sgraffito decoration, in which patterns were incised through a grayish-white slip, is also seen occasionally.

Some excellent painted designs in an underglaze blue of variable colour but usually distinctly grayish in tone were executed on a rough porcelain body that is almost stoneware. The designs are particularly notable for great economy of brushwork and superb drawing. Their affinities are much more with Japanese pottery than with contemporary Chinese wares. A typical Japanese technique, "brush" (*hakeme*), or brushed slip, is used in conjunction with painted decoration in the early part of the dynasty, but later it is used alone. Korean influence on Japanese pottery was probably at its strongest during the ascendancy of the Japanese warrior Hideyoshi (1536–98), who invaded Korea. It is unlikely that much important work was done in Korea itself after this invasion.

JAPAN

Since Japan is a well-wooded country, wood has always been used for domestic utensils of all kinds, either in a natural state or lacquered. Until recent times, therefore, pottery and porcelain were not employed extensively for general domestic use but were reserved for such special purposes as the tea ceremony (see below). In pottery the Japanese especially admire accidental effects that resemble natural forms. Objects that appear misshapen and glazes that exhibit what would normally be regarded as serious imperfections in the West are admired by the Japanese connoisseur. The Japanese potter liked his work to reveal the impress of the hand that had made it. Marks, such as the ridges left by the fingers in a newly thrown vessel, were frequently accentuated instead of being obliterated, and marks made by tools were often left untouched.

Accidental effects

Hand modelling was practiced long after the wheel was known, and asymmetries and irregularities of form were purposely sought. Similar accidental effects were encouraged in glazing: coloured glazes were allowed to run in streaks and were irregularly applied. They were often thick, with many bubbles, and with a semifluid or treacly appearance. Crackled glazes and those deeply fissured (the latter called dragon skin or lizard skin) were deliberately

induced. Painted decoration, frequently blue, brown, or iron red, is often summary and almost calligraphic in its simplicity. The aim was to give an overall effect that resembled such natural objects as stones, in being largely uncontrived.

From the 15th century onward, the art of the potter was also affected by the elaborate tea ceremony (the *cha-no-yu*). In its original form it was probably introduced from China by Zen priests, but at the court of the shogun (military governor) Yoshimasa (1435–90), in Kyōto, it developed into a fixed ceremonial pattern. Possibly the ceremony was first exploited as a means of settling feudal disputes. It is held in a small room or pavilion, usually surrounded by a carefully designed garden. When the guests are summoned they enter a sparsely furnished room through a very low doorway. The fact that guests must crawl into the room is thought to have served the purpose of preventing them from concealing a sword under their robes.

In a recess called the toko-no-ma, a picture mounted on brocade or silk is hung, and the guests bow to this in appreciation. The tea master puts a little powdered tea in a bowl and pours on it water that has been heated over a charcoal brazier. The tea is whipped to a froth with a bamboo whisk and then passed from hand to hand. The various utensils (the teabowl, tea caddy, water container, boxes, plates, and iron tea kettle) have been carefully selected by the tea master and are often of great age. The tea drinking is followed by a discussion and appreciation of the qualities of the utensils. The bowls are valued for their heat-retaining properties and the way in which they fit the hand as well as for their appearance. Sometimes a newly acquired work of art is produced by the host for the delectation of his guests. Since the tea masters were the aesthetic arbiters, their influence on Japanese pottery was profound.

Jōmon pottery

The early history of Japan is considerably more obscure than that of China. The first Japanese pottery belongs to the Jōmon period (*c.* 2500–250 BC). It has a black body, and the decoration is usually an impressed representation of coiled rope or matting (*jōmon* means "coiled"). *Jōmon-shiki* ("pottery") is widely distributed throughout the islands, but complete specimens are very rare. It was followed by Yayoi pottery, specimens of which have been excavated throughout Japan. The body is somewhat finer in quality than Jōmon pottery and is usually red or gray. Decoration is simple, and forms will sometimes show the influence of Korean pottery of the period. It ceased to be produced about the 6th century AD.

Meanwhile, from about the 3rd to the 6th century AD, large tombs were constructed in the form of oval or circular tumuli from whose bases have been recovered the *haniwa* ("clay circle") figures of warriors, women, horses, and so forth. They are hollow, and, though vigorously modelled, they are more primitive than analogous tomb figures from China.

In the Asuka or Sueki period (AD 552–710) that followed, wares are much more sophisticated. Unlike the preceding types, they were made with a wheel, and firing took place in a rudimentary kiln at a much higher temperature than previously. Widespread manufacture continued through the Nara period (710–794) and the early part of the following Heian, or Fujiwara, period (794–1185). Some examples have a smear glaze, no doubt at first caused accidentally by wood ashes coming into contact with the surface. Three colours of glaze—green, yellowish brown, and white—were used either alone or in combination and resemble those of T'ang earthenware. Pottery of this kind has been found around Ōsaka and Kyōto. The principal pottery productions of the period were vases, dishes, bowls, and bottles of various descriptions.

The influence of Korea and of T'ang China is noticeable. Toward the end of the Heian period contacts with China were severed, and there was a corresponding decline in the art of pottery; even the traditional Sueki ware disappeared.

Kamakura and Muromachi periods (1192–1573). A revival in the Kamakura period (1192–1333) followed the visit of the potter Katō Shirōzaemon (Tōshirō) to China in 1227, where he learned the secrets of pottery making. He established himself at Seto, Owari (now Aichi Prefecture), which speedily became a large centre of manufacture. There were soon about 200 kilns in the vicinity making a variety of wares, some of which were glazed in black in imitation of the *temmoku* wares of China (see above *China: Sung dynasty*). The early wares were mainly for ritual purposes, but by the beginning of the Muromachi, or Ashikaga, period (1338–1573) teabowls, plates, jars, and saucers of domestic utility were also being made. Wares of the Kamakura period are decorated with incised designs or with impressed or applied ornament. The Muromachi wares are much plainer as the result of the growing influence of the tea ceremony, especially the *wabi* school of the cult, which concentrated on rustic simplicity. The wares of both of these periods have a feldspathic glaze, but the Muromachi glaze is more even in quality than the Kamakura, which has a tendency to run in rivulets. A transitional type has a soft-yellowish glaze or a dark-brown glaze sometimes called Seto *temmoku*.

A large number of kilns were in existence, the more important known as the "six pottery centres of ancient Japan." These were Seto; Tokoname (also in Aichi Prefecture), which may have exceeded Seto in the size of its production; Bizen (Okayama Prefecture), which has produced an excellent unglazed stoneware from the Heian period to the 20th century; Tamba (Kyōto Prefecture); Shigaraki (Shiga Prefecture); and Echizen (Fukui Prefecture). The wares of Seto, especially those made for Buddhist ceremonies, were regarded as the finest pottery of this period.

Seto–Mino wares

Azuchi-Momoyama period (1573–1600). Production had been interrupted during the civil wars of the 15th and 16th centuries. Toward the end of the 16th century the Seto kilns were removed for a time to the Gifu Prefecture of Mino Province, where they received the protection of the feudal baron (daimyo) of Toki. The Mino pottery was founded by Katō Yosabei, whose sons started other potteries in the vicinity, notably that under the aegis of the tea master Furuta Oribe Masashige. New kilns were also built elsewhere, and pottery, while retaining its importance in the tea ceremony, became much more widely used for ordinary purposes. The inspiration for most of its shapes and designs came from the Mino region. The later wares of these kilns are much less austere than those attributed to the Muromachi period, since the cult of the tea ceremony, now widespread, had lost something of its earlier simplicity. Characteristic tea ceremony wares of the early years of the 17th century are Shino, which has a thick, crackled glaze and is sometimes summarily painted in blue or brown; yellow Seto (*ki-Seto*), whose crackled yellow glaze covers a stoneware body; and, at Narumi, in the adjoining Owari region, a ware of the kind associated with Oribe (which had become a generic term for pottery influenced by the tea master of that name), which is glazed in white, straw colour, yellowish green, and pinkish red, with sometimes the addition of slight painting in brown.

Toward the end of the 16th century the tea ceremony was reformed by Sen Rikyū (1521–91), the tea master to the military dictator of Japan, Toyotomi Hideyoshi. Sen Rikyū was principally responsible for the replacement of the hitherto much admired *temmoku* bowls from China by others patterned after unsophisticated Korean wares; his influence has persisted to the 20th century. In the 1590s Hideyoshi twice invaded Korea, and as a result of these wars many Korean potters were taken to Japan, where their influence was considerable.

Raku ware

A tilemaker named Ameya, who is said to have been a Korean, introduced a type of ware that was covered with a lead glaze and fired at a comparatively low temperature. His son Tanaka Chōjirō and his family extended this technique to the tea bowl, and in about 1588 their wares were brought to the notice of Hideyoshi, who awarded them a gold seal engraved with the word *raku* ("felicity"). The *raku* (Figure 142), made in Kyōto, are among the most famous of all Japanese wares. The shape of the vessels is extremely simple: a wide straight-sided bowl set on a narrow base. At first the glaze was dark brown, but a light orange red was developed later, to be followed in the 17th century by a straw colour. Still later, green and cream and other colours were introduced. Tea-bowls attributed to the first Chōjirō are greatly valued in Japan.

Karatsu ware

The kilns of Karatsu, a district in the north of Hizen Province, may have been established by Korean potters, since the influence of Korea is perceptible in some of them. The term Karatsu ware encompasses a great variety of shapes and styles: "undecorated" (*muji*), "painted" (*e*), "speckled" (*madara*), in the Korean style (Chosen), which has a thick opaque glaze, and in the style of Seto, which has a white glaze. The earliest Karatsu ware belongs probably to the end of the 16th century, although it is sometimes awarded a still earlier date. Most surviving examples belong to the 17th century. The most valued pieces are those made for the tea ceremony. (Ge.S.)

Edo period (1603–1867). According to tradition, the first Japanese porcelain was made in the early 16th century after Shonzui Goradoyu-go brought back the secret

By courtesy of the Metropolitan Museum of Art, New York, Rogers Fund, 1918

Figure 143: Kakiemon ware decorated with iron red and coloured enamels, Hizen Province, Japan, Edo period, 17th century. In the Metropolitan Museum of Art, New York. Diameter 24.4 cm.

of its manufacture from the Chinese kilns at Ching-te-chen. Another account claims that Ri Sampei, a Korean potter who was brought to Japan by Hideyoshi, discovered porcelain clay in the Izumi Mountain near Arita (Saga Prefecture); this version is feasible since no porcelain made before the end of the 16th century has been identified.

The first Arita manufacture was decorated in blue underglaze, simple and excellent in quality. Specimens soon found their way to Europe in Dutch ships, and the Dutch were awarded a trading monopoly in 1641. Some of these early Japanese export wares are based on contemporary European metalwork and faience.

The family of Sakaida is especially connected with the Arita kilns. The first recorded member, born about 1596, worked in underglaze blue until the family learned the secret of using overglaze colours. According to tradition, it was told to them by a Chinese met by chance in the port of Nagasaki. This overglaze technique was perfected soon after the middle of the 17th century. It was continued by the family, and, since many of them were called Kakiemon, the style has become known by that name. The palette is easily recognized—iron red, bluish green, light blue, yellow, and sometimes a little gilding; many examples have a chocolate-brown rim. Octagonal and square shapes are especially frequent (Figure 143). Themes of decoration are markedly asymmetrical, with much of the white porcelain surface left untouched. This technique and style spread rapidly to other provinces, and its influence on porcelain that was manufactured in Europe during the first half of the 18th century was at least as great as that of Chinese porcelain. A later Kakiemon development in which "brocade" (*nishikide*) patterns in compartments were used (at the suggestion of Dutch traders) proves to be less pleasing. These later coloured wares from Arita became known as Imari, after the port from which they were shipped.

Kakiemon porcelain

Like 18th-century Chinese white porcelain, Japanese white wares were shipped to Europe, where they were decorated by Dutch and other European enamellers.

Of considerable importance but more rarely seen in Europe is the porcelain called Kutani. The kiln at Kutani in Kaga Province (now in Ishikawa Prefecture) operated in the latter half of the 17th century. Greatly valued, Old Kutani (*ko*-Kutani) porcelain is among the finest of the Japanese wares. The body is heavy, approaching stonewares, and the designs are executed boldly and in rich colours. Old Kutani was revived and other styles arose when kilns in the area resumed operation in the early 19th century and again in the 1860s, the latter resulting in the establishment of modern "Kutani ware" as a major export item.

The Mikawachi kilns under the protection of the prince of Hirado made porcelain principally for his use. The delicate, very white body is usually decorated in miniature style with underglaze blue. Kyōto imitated Sung celadons and the Ming green and red wares. Seto made no porcelain until about 1807; the first production was decorated in underglaze blue (*sometsuke*). Overglaze colours date from about 1835.

The manufacture of earthenware was continued during the 17th and 18th centuries, and much of it is notable for its decoration. Toward the end of the 17th century, Ninsei (Nonomura Seisuke) began work at Kyōto and was responsible for much finely enamelled decoration on a cream earthenware body covered with a finely crackled glaze. Also produced at Kyōto, the works of Kenzan, who used rich and subtly coloured slips often as a background for plant motives, and of the Dōhachi family, famous for their overglaze decoration, are much sought after in Japan.

19th and 20th centuries. Japanese productions during the 19th century, in common with those in most other parts of the world, greatly deteriorated in taste. Typical of the period is the so-called Satsuma pottery, most of which was made not at Satsuma but at Kyōto and then sent to Tokyo to be decorated especially for export. The designs are overcrowded and debased, and its popularity undoubtedly retarded an appreciation of work in the true Japanese taste among Western students and collectors.

Satsuma pottery

Like Western pottery manufacture in the mid-20th century, Japan's is largely industrialized, and most products are derivative, but the Japanese tradition of pottery making in small and private kilns continues. (Ge.S./Ed.)

THAILAND AND ANNAM

Pottery was made in the old Siamese capitals of Sukhothai and Sawankhalok. It is also thought that potteries persisted at Ayutthaya until the 18th century. Little is known of the early history of the region, and definite information on its pottery is almost nonexistent. Dating of the pottery from these regions for the most part has been by ana-

logy with related Chinese wares, which greatly influenced Siamese work.

Kilns have been excavated on the site of old Sawankhalok, about 200 miles (320 kilometres) north of Bangkok. The principal type of ware is a grayish-white stoneware covered with a translucent celadon glaze, usually grayish green in colour. The glaze is commonly crackled; this appears to be fortuitous, since little trouble was taken to achieve a precise finish. A particularly common decoration consists of roughly scored vertical flutes, with incised circles at the shoulder to accentuate the form. Decoration of a more definite kind is always incised under the glaze and is usually floral. Flowers are stylized, sometimes with combed lines on the petals. Covered bowls, dishes, ewers, and bottles with two small loop handles at the neck are the most common forms.

Another type of ware, with similar forms, has a rather treacly-brown glaze. Some well-modelled animals are found with this glaze. There are also tiles and bricks with crudely modelled figures in relief on them. They are analogous in form and technique to Chinese pottery of the Sung dynasty and are generally regarded as being contemporary with the Sung or Yüan period. Some small covered jars of a gray porcelaneous ware, summarily decorated with stylized floral and foliate patterns, appear to have been made at Sawankhalok (the date is probably equivalent to that of the early Ming period). These Martabani wares were widely exported throughout the East during this period.

Little is known of wares made in Annam, but some brownish celadons are regarded as likely to have been made there, as well as some small covered jars painted in a poor underglaze blue.

American Indian pottery

The American Indians are of Asiatic descent; their route to the New World was from Siberia into Alaska across the Bering Straits. The usually quoted period of their migration is between 40,000 and 10,000 years ago. Since they were nomadic peoples, it is unlikely that they brought the knowledge of pottery making with them. When pottery making did begin, it was fundamentally unlike any known work from the Old World, and the few remote resemblances to Oriental motifs are almost certainly fortuitous. The wheel remained unknown until the arrival of Europeans, although there is reason to think that a turntable, or slow wheel, may have been used occasionally. Most of the pottery was made by coiling, some by molding—both are techniques that could have arisen spontaneously. It is likely that most of the work was done by women rather than by the men. This is nearly always the case with primitive potters when the wheel is not used, and Pueblo Indian women still do this kind of work.

Slips were used to cover the body, and coloured slips provided the material for much of the painted freehand decoration. Glazes are rare, although examples can be found among the Pueblo Indians of New Mexico from about AD 1300 onward, on a few vessels from the Chimú area in the Andes, and occasionally in Central America. The effect of a reducing atmosphere was understood, so that gray and black pots are found as well as the red and brown ones fired in an oxidizing flame. Undecorated surfaces were often highly polished.

NORTH AMERICA

The most important North American pottery was made in the southwest—an area including Arizona, New Mexico, and also parts of Utah and Colorado. The people who inhabited the plateau land from about 100 BC are often referred to as the Anasazi, a Navaho Indian word meaning ancient people. They are the ancestors of the Pueblo, who began to emerge about AD 700. The Anasazi were nomadic hunters; although they did not at first make pottery, they did make excellent baskets. Fixed dwellings appear about AD 50, and this probably marks the beginning of pottery manufacture. The earliest pots appear to have been baskets that were smeared with clay and then dried in the sun.

Next came basket-shaped wares coiled in a gray body, used principally for cooking. They were followed by more decorative bowls and pots, with striking black and white geometric designs that seem to have been executed about AD 700. Slightly later there is another type of ware that has black decoration on a red slip. After the 12th century the earlier types began to disappear and were replaced by polychrome wares decorated with stylized birds, feathers, animals, and human figures amid the geometric patterns. The principal colours are yellow and red. A small quantity of glazed ware was made in the Zuñi area of New Mexico.

The Hohokam tribes (a Pima word meaning "those who have gone"), who lived in the desert of southern Arizona and were approximately contemporary with the Anasazi, made pottery figures for religious purposes, usually of crudely modelled naked women. Some of this pottery is a gray ware, but most of it is buff, with decoration in iron red that has a quality lacking the stiffness of the Pueblo designs.

Pottery figures for religious purposes

The Mogollon culture of New Mexico produced, during the Mimbres period of the 11th and 12th centuries, a ware remarkable for its lively black and white decoration depicting human, animal, and insect forms in a much less stylized manner than the paintings on most other wares from the southwest.

There is little pottery of importance from other parts of the United States. Primitive pots have been found on the Atlantic coast, in Georgia and Florida, on the Gulf Coast, and elsewhere, some of which are based on basketwork. Geometric decoration, usually incised, is the rule. Eskimo pottery, which is generally rather crude, bears some resemblance to early Asiatic types.

CENTRAL AMERICA

The pottery of Mexico and the rest of Central America is of considerable interest, but the wares are so diverse that it is impossible to summarize them adequately. They probably date from the 2nd millennium BC onward and were made by the Mayas, the Zapotecs, the Toltecs, and the Aztecs. Generally speaking, geometric patterns are common, and slips in black, brown, white, or red were frequently used. A curiosity of Central America (possibly adopted from South America) is a technique that resembles to some degree the batik method of dyeing textiles.

The surface of the pot was coated either with wax or gum. This was then scraped away in part to form a predetermined pattern, and the whole surface of the pot was covered with pigment. In firing, the gum burned away, leaving only the scraped parts in colour. Ornament carved in low relief after firing is to be seen occasionally and has few parallels outside the Americas. An unusual tech-

Maya, Zapotec, Toltec, and Aztec pottery

nique from the Mexican highlands consisted of covering the whole surface of the pot with a kind of thick slip, most of which was then scraped away, leaving only thin partitions. These compartments were filled with slips of a contrasting colour. The commonest shapes are bowls and wide-mouthed vases; many of these were made with legs, usually three, so that they could be set down on uneven ground. Figurines, some of which are painted, have also been found.

Between about 600 BC and AD 1000, the Mayas were making an excellent polychrome pottery in which designs in red and black were painted on a cream or orange slip. Between roughly the 4th and the 10th centuries AD, the Zapotecs, whose chief ceremonial site was Monte Albán in Oaxaca State, made striking urns in the forms of their gods. An orange-coloured pottery decorated in a great diversity of styles is associated with the Toltecs, as is a dark-coloured pottery with a glossy appearance and incised ornament (plumbate ware). Both of these types were widely distributed throughout Central America from the 11th to 14th centuries. Little is known of the Aztecs until about 1325, the date of the foundation of Tenochtitlán (Mexico City). Much of their later pottery utilizes an orange-burning clay that was painted with black curvilinear geometric motifs, in contrast to their earlier rectilinear style. During the period of Montezuma I in the 15th century, designs became more naturalistic, and birds, fish, and plant forms were freely utilized. European motifs first appear after the conquest, and such techniques as tin glazing were used from the 17th century onward.

SOUTH AMERICA

Most South American pottery was made at centres in the Andes and on the west coast, particularly in Bolivia and Peru. Pottery of lesser importance comes from Ecuador, Colombia, northwest Argentina, and northern Chile. In some places a very high degree of skill was attained, especially in the central Andes, where the earliest wares seem to date from the end of the 2nd millennium BC. Much of the pottery was made in molds. The stirrup-shaped spout on many jars is a characteristic feature. The batik type of decoration already mentioned was also used. Vessels were modelled in the shape of animal or human figures, which were also used as motifs for painted decoration. The puma god worshipped by the early peoples appears in many forms. Depictions of erotic themes also appear in South American pottery, particularly in the Mochica and Chimú cultures.

Mochica culture

The work of the Mochica culture, which flourished around the northern coast of Peru, is at its best about the 7th century AD. Jars in the form of human heads, some of which may be portraits, are remarkable both for the naturalism of the treatment and the skill of the potter. These have the stirrup spout (Figure 144). Painted decoration is often stylized although with a considerable degree of realism, and the subjects are nearly always ceremonial or religious nature.

The pottery of the Nazcas, who lived on the southern coast of Peru at much the same period, is noted for its painting. A varied palette included several shades of red and blue, yellow, orange, green, brown, black, gray, and white. The stirrup spout here becomes two spouts joined by a flat bridge. The earliest painting is on a red ground, white grounds becoming more common later. Geometric patterns are to be seen in conjunction with stylized birds, human heads, and the like. The naturalistic portrait jars of the Mochica do not appear, but there are some vessels in the form of figures modelled in a much more conventional style and similarly painted. Puma's heads occur in relief, with the body of the animal completed in brushwork. The centipede god is a motif that does not appear elsewhere.

The people of Tiahuanaco, who lived in the region around Lake Titicaca, were influenced by the Nazca wares, though painted decoration, often carried out on a red slip ground, is more limited in colour than the Nazca. The puma head was used as a motif. In general, decoration is extremely stylized with a very strong geometric flavour.

Chimú culture

The Chimú culture succeeded the Mochica in the northern area and lasted until the arrival of the Incas. The most familiar ware is in a body that varies from gray to black, although a red polished ware, sometimes painted in white slip, was also made. The influence of the Mochica tradition can be seen in the retention of the stirrup spout on some jars; others have the double spout connected by a flat bridge. The modelled wares of the Mochica culture were also revived but are of a generally inferior quality.

The Incas originally settled in Cuzco, the old capital of Peru, at the end of the 11th century. During the 15th century they established themselves over a wide area, including the territory of the Chimús. They were principally soldiers and administrators with small inclination toward luxury; and their pottery, of excellent quality particularly in the 15th century, is designed without an excess of decoration. Most Inca pottery is red polished ware. It is usually painted with geometric designs in red, white, and black, although relief decoration is also seen on black ware, especially from the Chimú region.

The commonest surviving form has been called an aryballos, although its resemblance to the Greek form is remote and fortuitous. It has a conical base, and the neck finishes in a flaring mouth. Two loop handles are set low on the body. The assumption that this vessel was made for carrying water on the back seems a little doubtful in view of its shape and the disposition of the handles. Little fine pottery was made after the arrival of the Spaniards in the 16th century. (Ge.S.)

BASKETRY

Basketry in myth

The Babylonian god Marduk "plaited a wicker hurdle on the surface of the waters. He created dust and spread it on the hurdle." Thus ancient Mesopotamian myth describes the creation of the earth using a reed mat. Many other creation myths place basketry among the first of the arts given to man. The Dogon of West Africa tell how their first ancestor received a square-bottomed basket with a round mouth like those still used there in the 20th century. This basket, upended, served him as a model on which to erect a world system with a circular base representing the sun and a square terrace representing the sky.

Like the decorative motifs of any other art form, the geometric, stylized shapes may represent natural or supernatural objects, such as the snakes and pigeon eyes of Borneo, and the kachina (deified ancestral spirit), clouds, and rainbows of the Hopi Indians of Arizona. However, the fact that these motifs are given a name does not always mean they have symbolic significance or express religious ideas.

Sometimes symbolism is associated with the basket itself. Among the Guayaki indians of eastern Paraguay, for example, it is identified with the female: the men are hunters, the women are bearers as they wander through the forest; when a woman dies, her last burden basket is ritually burned and thus dies with her.

Though it would appear that basketry might best be defined as the art or craft of making baskets, the fact is that the name is one of those the limits of which seem increasingly imprecise the more one tries to grasp it. The category basket may include receptacles made of interwoven, rather rigid material, but it may also include pliant sacks made of a mesh indistinguishable from netting—or garments or pieces of furniture made of the same materials and using the same processes as classical basketmaking. In fact, neither function nor appearance nor material nor mode of construction are of themselves sufficient to delimit the field of what common sense nevertheless recognizes as basketry.

In this section the word will be taken to mean a handmade assemblage of vegetable fibres that is relatively large and rigid, so as to make a continuous surface, usually (but not exclusively) a receptacle. The consistency of the mate-

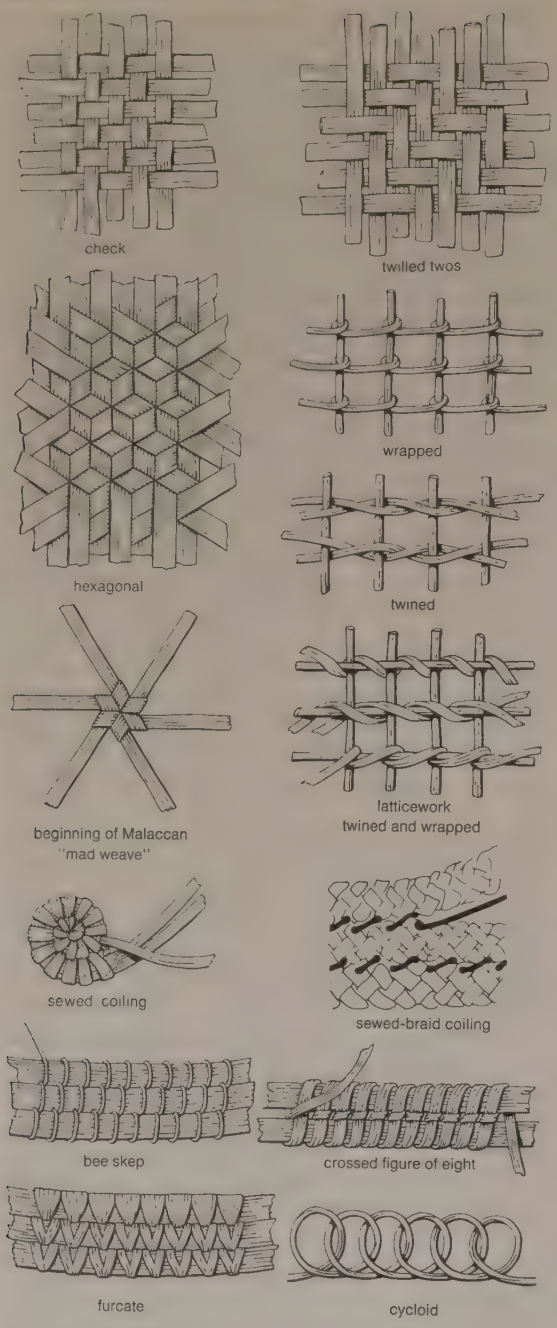

Figure 145: Varieties of plaited and coiled work used in basketry.

rials used distinguishes basketry, which is handmade, from weaving, in which the flexibility of the threads requires the use of an apparatus to put tension on the warp, the lengthwise threads. What basketry has in common with weaving is that both are means of assembling separate fibres by twisting them together in various ways.

This section deals with the construction materials and techniques of basketry as well as their symbolism, uses, and history.

Materials and techniques

There is no region in the world, except in the northernmost and southernmost parts, where people do not have at their disposal materials—such as twigs, roots, canes, and grasses—that lend themselves to the construction of baskets. The variety and quality of materials available in a particular region bears on the relative importance of basketry in a culture and on the types of basketry produced by the culture. Rainy, tropical zones, for example, have palms and large leaves that require plaiting techniques different from those required for the grass stalks that predominate in the dry, subtropical savanna regions or for the roots and stalks found in cold temperate zones. The interrelationship between materials and methods of construction might in part explain why the principal types of basketry are distributed in large areas that perhaps correspond to climatic zones as much as to cultural groups: the predominance of sewed coiling, for example, in the African savannas and in the arid zones of southern Eurasia and of North America; of spiral coiling and twining in temperate regions; and of various forms of plaiting in hot regions. There is also a connection between the materials used and the function of the basket, which determines whether rigid or soft materials—either as found in nature or specially prepared—are used. In East Asia, for example, twined basketry fashioned out of thin, narrow strips (called laths) of bamboo is effective for such objects as cages and fish traps that require solid partitions with openings at regular intervals. Soft and rigid fibres are often used together: the rigid fibres provide the shape of the object and soft ones act as a binder to hold the shape.

Aesthetic goals and choice of material

Finally, materials are chosen with a view toward achieving certain aesthetic goals; conversely, these aesthetic goals are limited by the materials available to the basket maker. The effects most commonly sought in a finished product are delicacy and regularity of the threads; a smooth, glossy surface or a dull, rough surface; and colour, whether natural or dyed. Striking effects can be achieved from the contrast between threads that are light and dark, broad and narrow, dull and shiny—contrasts that complement either the regularity or the decorative motifs obtained by the intricate work of plaiting.

Despite an appearance of almost infinite variety, the techniques of basketry can be grouped into several general types according to how the elements making up the foundation (the standards, which are analogous to the warp of cloth) are arranged and how the moving element (the thread) holds the standards by intertwining among them (Figure 145).

Coiled construction. The distinctive feature of this type of basketry is its foundation, which is made up of a single element, or standard, that is wound in a continuous spiral around itself. The coils are kept in place by the thread, the work being done stitch by stitch and coil by coil. Variations within this type are defined by the method of sewing, as well as by the nature of the coil, which largely determines the type of stitch.

Spiral coiling. The most common form is spiral coiling (Figure 146), in which the nature of the standard introduces two main subvariations: when it is solid, made up of a single whole stem, the thread must squeeze the two coils together binding each to the preceding one (giving a diagonal, or twilled, effect); with a double or triple standard the thread catches in each stitch one of the standards of

By courtesy of H. Balfet

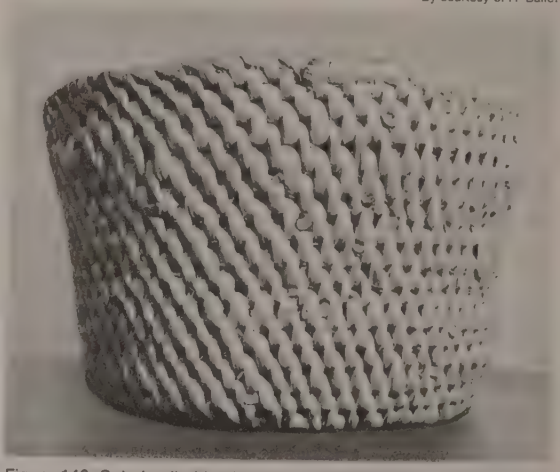

Figure 146: Spiral-coiled basket with twill effect, from Bialystok region, Poland. In the Musée de l'Homme, Paris.

the preceding coil. Many other variations of spiral coiling are possible. Distribution of this type of basketry construction extends in a band across northern Eurasia and into northwest North America; it is also found in the southern Pacific region (China and Melanesia) and, infrequently, in Africa (Rhodesia).

Sewed coiling. Sewed coiling (Figure 147) has a foundation of multiple elements—a bundle of fine fibres. Sewing is done with a needle or an awl, which binds each coil to the preceding one by piercing it through with the thread. The appearance varies according to whether the thread conceals the foundation or not (bee-skep variety) or goes through the centre of the corresponding stitch on the preceding coil (split stitch, or furcate). This sewed type of coiled ware has a very wide distribution: it is almost the exclusive form in many regions of North and West

Distribution of sewed coiling

Africa; it existed in ancient Egypt and occurs today in Arabia and throughout the Mediterranean basin as far as western Europe; it also occurs in North America, in India, and sporadically in the Asiatic Pacific. A variety of sewed coiling, made from a long braid sewed in a spiral, has been found throughout North Africa since ancient Egyptian times.

Half-hitch and knotted coiling. In half-hitch coiling, the thread forms half hitches (simple knots) holding the coils in place, the standard serving only as a support. There is a relationship between half-hitch coiling and the half-hitch net (without a foundation), the distribution of which is much more extensive. The half-hitch type of basketry appears to be limited to Australia, Tasmania, Tierra del Fuego in South America, and Pygmy territory in Africa. In knotted coiling, the thread forms knots around two successive rows of standards; many varieties can be noted in the Congo, in Indonesia, and among the Basket Makers, an ancient culture of the plateau area of southwestern United States, centred in parts of Arizona, New Mexico, Colorado, and Utah.

The half-hitch and knotted-coiling types of basketry each have a single element variety in which there is no foundation, the thread forming a spiral by itself analogous to the movement of the foundation in the usual type. An openwork variety of the single element half hitch (called cycloid coiling) comes from the Malay area; and knotted single-element basketry, from Tierra del Fuego and New Guinea.

Noncoiled construction. Compared to the coiled techniques, all other types of basketry have a certain unity of construction: the standards form a foundation that is set up when the work is begun and that predetermines the shape and dimensions of the finished article. Nevertheless, if one considers the part played by the standards and the threads, respectively, most noncoiled basketry can be divided into three main groups.

Wattle construction. A single layer of rigid, passive, parallel standards is held together by flexible threads in one of three ways, each representing a different subtype. (1) The bound, or wrapped, type, which is not very elaborate, has a widespread distribution, being used for burden baskets in the Andaman Islands in the Bay of Bengal, for poultry cages in different parts of Africa and the Near East, and for small crude baskets in Tierra del Fuego. (2) In the twined type, the threads are twisted in twos or threes, two or three strands twining around the standards and enclosing them. The twining may be close or openwork or may combine tight standards and spaced threads. Close twining mainly occurs in three zones: Central Africa, Australia, and western North America, where there are a number of variations such as twilled and braided twining and zigzag or honeycomb twining. The openwork subtype is found almost universally because it provides a perfect solution to the problem of maintaining rigid standards with even spacing for fish traps and hurdles (portable panels used for enclosing land or livestock). Using spaced threads, this subtype is also used for flexible basketry among the Ainu of northern Japan and the Kuril Islands and sporadically throughout the northern Pacific. (3) The woven type (Figure 148), sometimes termed wickerwork, is made of stiff standards interwoven with flexible threads. It is the type most commonly found in European and African basketry and is found sporadically in North and South America and in Near and Far Eastern Asia.

Lattice construction. In lattice construction a frame made of two or three layers of passive standards is bound together by wrapping the intersections with a thread. The ways of intertwining hardly vary at all and the commonest is also the simplest: the threads are wrapped in a spiral around two layers of standards. This method is widely used throughout the world in making strong, fairly rigid objects for daily use: partitions for dwellings, baskets to be carried on the back, cages, and fish traps (with a Mediterranean variety composed of three layers of standards and a knotted thread). The same method, moreover, can be adapted for decorative purposes, with threads—often of different colours—to form a variety of motifs similar to embroidery. This kind of lattice construction appears mainly among the Makah Indians of the U.S. Pacific Northwest and in Central and East Africa.

Uses of lattice construction

Matting or plaited construction. Standards and threads are indistinguishable in matting or plaited construction; they are either parallel and perpendicular to the edge (straight basketry) or oblique (diagonal basketry) (Figure 149). Such basketry is closest to textile weaving. The mate-

rials used are almost always woven, using the whole gamut of weaving techniques (check, twill, satin, and innumerable decorative combinations). Depending on the material and on the technique used, this type of construction lends itself to a wide variety of forms, in particular to the finest tiny boxes and to the most artistic large plane surfaces. It is widely distributed but seems particularly well adapted to the natural resources and to the kind of life found in intertropical areas. The regions where it is most common are different from, and complementary with, those specializing in coiled and twined ware; that is, eastern and southeastern Asia (from Japan to Malaysia and Indonesia), tropical America, and the island of Madagascar off the east coast of Africa.

One variety of matting or plaited work consists of three or four layers of elements, which are in some cases completely woven and in others form an intermediate stage between woven and lattice basketry. The intermediate type (with two layered elements, one woven) is known as hexagonal openwork and is the technique most common in openwork basketry using flat elements. It has a very wide distribution: from Europe to Japan, southern Asia, Central Africa, and the tropical Americas. A closely woven fabric in three layers, forming a six-pointed star design, is found on a small scale in Indonesia and Malaysia.

Decorative devices. Clearly, a variety of decorative possibilities arise from the actual work of constructing basketry. These, combined with the possible contrasts of colour and texture, would seem to provide extensive decorative possibilities. Each particular type of basketry, however, imposes certain limitations, which may lead to convergent effects: hexagonal openwork, for example, forms the same pattern the world over, just as twilled weaving forms the same chevrons (vertical or horizontal). Each type, also, allows a certain range of freedom in the decoration within the basic restrictions imposed by the rigidity of the interlaced threads, which tends to impose geometric designs or at least to geometrize the motifs. In general, the two main types of basketry—plaited and coiled—lend themselves to two different kinds of decoration. Coiled basketry lends itself to radiating designs, generally star- or flower-shaped compositions or whirling designs sweeping from the centre to the outer edge. Plaited basketry, whether diagonal or straight, lends itself to over-all compositions of horizontal stripes and, in the detail, to intertwined shapes that result from the way two series of threads, usually in contrasting colours, appear alternately on the surface of the basket.

Typical coiled and plaited basketry decorations

Other art forms have been influenced ornamentally by basketry's plaited shapes and characteristic motifs. Because of their intrinsic decorative value—and not because the medium dictates it—these shapes and motifs have been reproduced in such materials as wood, metal, and clay. Some notable examples are the interlacing decorations carved on wood in the Central African Congo; basketry motifs engraved into metalwork and set off with inlayed silver by Frankish artisans in the Merovingian period (6th to 8th century); and osier patterns (molded basketwork designs) developed in 18th-century Europe to decorate porcelain.

Uses

Household basketry objects consist primarily of receptacles for preparing and serving food and vary widely in dimension, shape, and watertightness. Baskets are used the world over for serving dry food, such as fruit and bread, and they are also used as plates and bowls. Sometimes—if made waterproof by a special coating or by particularly close plaiting—they are used as containers for liquids. Such receptacles are found in various parts of Europe and Africa (Chad, Rwanda, Ethiopia) and among several groups of North American Indians. By dropping hot stones into the liquid, the Hupa Indians of northwestern California even boil water or food in baskets.

Waterproofing

Openwork, which is permeable and can be made with mesh of various sizes, is used for such utensils as sieves, strainers, and filters. Such basketry objects are used in the most primitive cultures as well as in the most modern (the tea strainers used in Japan, for example). The flexibility of work done on the diagonal is put to particularly ingenious use by the Africans in beer making and, above all, by Amazonian Indians in extracting the toxic juices from manioc pulp (a long basketwork cylinder is pulled down at the bottom by ballasting and, as it gets longer, compresses the pulp with which it had previously been filled).

Finally, basketry plays an important part as storage containers. For personal possessions, there are baskets, boxes, and cases of all kinds—nested boxes from Madagascar, for example, which are made in a graduated series so that they fit snugly one within another, or caskets with multiple compartments from Indonesia. For provisions, there

are baskets in various sizes that can be hung up out of the reach of predators, and there are baskets so large that they are used as granaries. In The Sudan in Africa, as in southern Europe, these are usually raised off the ground on a platform and sheltered by a large roof or stored in the house, particularly in Mediterranean regions; for preserving cereals they are sometimes caulked with clay.

Some of these granaries are not far from being houses. Basketry used in house construction, however, usually consists of separately made elements that are later assembled; partitions of varying degrees of rigidity used as walls or to fence in an enclosure; roofs made of great basketry cones (in Chad, for example); and, above all, mats, which have numerous uses in the actual construction as well as in the equipping of a house. Probably the oldest evidence of basketry is the mud impressions of woven mats that covered the floors of houses in the Neolithic (*c.* 7000 BC) village of Jarmo in northern Iraq. Mats were used in ancient Egypt to cover floors and walls and were also rolled up and unrolled in front of doorways, as is shown by stone replicas decorating the doorways of tombs dating from the Old Kingdom, *c.* 2686–2160 BC. It is known from paintings that they were made of palm leaves and were decorated with polychrome (multicoloured) stripes, much like the mats found in Africa and the Near East.

Woven mats

Two notable examples of modern mats are the pliant ones, made of pandanus leaves, found in southern Asia and Oceania and the tatami, which provide the unit of measurement of the surface area of Japanese dwellings. Just as basketry has been used for making containers and mats, so from ancient times to modern it has been used for making such pieces of furniture as cradles, beds, tables, and various kinds of seats and cabinets.

In addition to the use of basketry for skirts and loincloths (particularly common in Oceania), supple diagonal plaiting has even been used to make dresses (Madagascar). Plaited raincoats exist throughout eastern Asia as well as Portugal. Basketry most frequently is used for shoes (particularly sandals, some of which come close to covering the foot and are plaited in various materials), and, of course, for hats—the conical hat particularly common in eastern Asia, for example, and the skullcaps and brimmed hats found in Africa, the Americas, and much of Europe.

To protect head and body against weapons, thick, strong basketry has been used in the form of helmets (Africa, the Assam region in India, and Hawaii); armour (for example, armour of coconut palm fibre for protection against weapons made of sharks' teeth by the Micronesia inhabitants of the Gilbert Islands); and shields, for which basketry is eminently suitable because of its lightness. In addition to clothes themselves, there are numerous basketry accessories: small purses, combs, headdresses, necklaces, bracelets, and anklets. In West Africa there are even chains made of fine links and pendants plaited in a beautiful, bright yellow straw in imitation of gold jewelry. Many objects are plaited just for decoration or amusement such as ornaments like those used for Christmas trees or for harvest festivals and scale models and little animal or human figurines that sometimes serve as children's toys.

There is often no very clear distinction between accessories and ritual ornaments, as in the ephemeral headdresses made for initiation rites by the young Masa people in the Cameroon; dance accessories; ornaments for masks, such as the leaf masks that the Bobo of Upper Volta make with materials from the bush.

More clearly ritual in nature are the palms (woven into elaborate geometric shapes and liturgical symbols) carried in processions on Palm Sunday by Christians in various Mediterranean regions; some, like those from Elche in Spain, are over six feet (nearly two metres) high and take days to make. In Bali an infinite variety of plaiting techniques are involved in the preparation of ritual offerings, which is a permanent occupation for the women, a hundred of whom may work for a month or two preparing for certain great festivals.

Baskets as snares

Baskets are used throughout the world as snares and fish traps, which allow the catch to enter but not to leave. They are often used in conjunction with a corral (on land) or a weir (an enclosure set in the water), which are themselves made either of pliable nets or panels of basketry. In Africa as well as in eastern Asia a basketry object is used for fishing in shallow water; open at top and bottom, this object is deposited sharply on the bottom of shallow rivers or ponds, and, when a fish is trapped, it is retrieved by putting a hand in through the opening at the top.

Basketry is also used in harvesting foodstuffs; for example, in the form of winnowing trays (from whose French name, *van*, the French word for basketry, *vannerie*, is derived). One basket, found in the Sahel region south of the Sahara, is swung among wild grasses and in knocking against the stalks collects the grain.

Baskets are used as transport receptacles; they are made easier to carry by the addition of handles or straps depending on whether the basket is carried by hand, on a yoke, or on the back. The two-handled palm-leaf basket, common in North Africa and the Middle East, existed in ancient Mesopotamia; in Europe and eastern Asia, the one-handled basket, which comes in a variety of shapes, sizes, and types of plaiting, is common; in Africa, however, where burdens are generally carried on the head, there is no difference between baskets used for transporting goods and those used for storing.

Burden baskets are large, deep baskets in which heavy loads can be carried on the back; they are provided either with a headband that goes across the forehead (especially American Indian, southern Asia), or with two straps that go over the shoulders (especially in Southeast Asia and Indonesia). There are three fairly spectacular types of small basketry craft found in regions as far apart as Peru, Ireland, and Mesopotamia: the balsa (boats) of Lake Titicaca, made of reeds and sometimes fitted out with a sail also made of matting; the British coracle, the basketry framework of which is covered with a skin sewn onto the edge; and the gufa of the Tigris, which is round like the coracle and made of plaited reeds caulked with bitumen.

Origins and centres of development

Something about the prehistoric origins of basketry can be assumed from archaeological evidence. The evidence that does exist from Neolithic times onward has been preserved because of conditions of extreme dryness (Egypt, Peru, southern Spain) or extreme humidity (peat bogs in northern Europe, lake dwellings in Switzerland); because it had been buried in volcanic ash (Oregon); or because, like the mats at Jarmo, it left impressions in the mud or on a pottery base that had originally been molded onto a basketry foundation. More recently, when written and pictorial documentation is available, an activity as humble and banal as basketry is not systematically described but appears only by chance in narratives, inventories, or pictures in which basketry objects figure as accessories.

On the evidence available, researchers have concluded that the salient characteristics of basketry are the same today as they were before the 3rd millenium BC. Then, as now, there was a wide variety of types (and a wide distribution of most types): coiled basketry either spiral or sewed, including furcate and sewed braid (mainly in Europe and the Near East as far as the Indus valley); wattlework with twined threads (America, Europe, Egypt) and with woven threads (Jarmo, Peru, Egypt); and plaited construction with twilled weaving (Palestine, Europe).

To list the centres of production would almost be to list all human cultural groups. Some regions, however, stand out for the emphasis their inhabitants place on basketry or for the excellence of workmanship there.

American Indian basketry. In western North America the art of basketry has attained one of its highest peaks of perfection and has occupied a preeminent place in the equipment of all the groups who practice it. North American Indians are particularly noted for their twined and coiled work. The Chilkat and the Tlingit of the Pacific Northwest are known for the extreme delicacy of their twined basketry; the California Indians, for the excellence of their work with both types; and the Apache and the Hopi and other Pueblo Indians of the southwestern interior of the United States, for coiled basketry remarkable for its bold decoration and delicate technique.

Figure 150: Basketry mask, from the Sepik region of New Guinea. In the Musée de l'Homme, Paris.

By courtesy of the Musee de l'Homme, Paris

Central and South American basketry is similar in materials and plaiting processes. The notable difference lies in the finishes used, and in this the Guyana Indians of northeastern South America excel, using a technique of fine plaiting with a twill pattern.

Plaiting processes in Oceania

Oceanic basketry. Various plaiting processes have been highly developed in Oceania, not merely for making utilitarian articles but also for ceremonial items and items designed to enhance prestige, such as finely twined cloaks in New Zealand, statues in Polynesia, masks in New Guinea (Figure 150), and decorated shields in the Solomon Islands. In Oceania, as in southern Asia, there is a vegetal civilization, in which basketry predominates over such arts as metalwork and pottery. Particular mention should be made of the Senoi of the Malay Peninsula and of the Australian Aborigines, whose meagre equipment includes delicate basketry done by the women. The Senoi use various plaiting techniques, and the Australians use tight twining.

African basketry. Africa presents an almost infinite variety of basket types and uses. In such regions as Chad and Cameroon, basketry is in evidence everywhere—edging the roads, roofing the houses, decorating the people, and providing the greater part of domestic equipment. The delicate twill plaited baskets of the Congo region are notable for their clever patterning. In the central and eastern Sudanese zone the rich decorative effect of the sewed, coiled baskets is derived from the interplay of colours. People living in the lake area of the Great Rift Valley produce elegant coiled and twined basketry of restrained decoration and careful finishing.

East Asian basketry. People of the temperate zones of East Asia produce a variety of work. Bamboo occupies a particularly important place both in functional basketry equipment and in aesthetic objects (Japanese flower baskets, for example). The production of decorative objects is one feature that distinguishes East Asian basketry from the primarily utilitarian basketry of the Near East and Africa. Southeast Asia, together with Madagascar, are among the places known for their fine decorative plaiting techniques.

European basketry. In Europe almost the whole range of basketry techniques is used, chiefly in making utilitarian objects (receptacles for domestic and carrying purposes and household furniture) but also in making objects primarily for decorative use.

Modern basketry. Even in the modern industrial world, there seems to be a future for basketry. Because of its flexibility, lightness, permeability, and solidity, it will probably remain unsurpassed for some utilitarian ends; such articles, however, because they are entirely handmade, will gradually become luxury items. As a folk art, on the other hand, basketry needs no investment of money: the essential requirements remain a simple awl, nimble fingers, and patience. (He.Ba.)

METALWORK

Man's first materials were stone, wood, bone, and earth. It was not until he had reached a later stage of evolution that he was able to extract and work with metals. This section deals with the objects that man has fashioned from copper, bronze and brass, gold and silver, iron, and lead: vessels, utensils, ceremonial and ritualistic objects, decorative objects, architectural ornamentation, personal ornament, sculpture, and weapons. It treats the processes and techniques and the stylistic characteristics and historical developments of metalworking.

General processes and techniques

Many of the technical processes in use today are essentially the same as those employed in ancient times. The early metalworker was familiar, for example, with hammering, embossing, chasing, inlaying, gilding, wiredrawing, and the application of niello, enamel, and gems.

Hammering and casting. All decorative metalwork was originally executed with the hammer. The several parts of each article were hammered out separately and then were put together by means of rivets, or they were pinned on a solid core (for soldering had not yet been invented). In addition, plates of hammered copper could be shaped into statues, the separate pieces being joined together with copper rivets. A life-size Egyptian statue of the pharaoh Pepi I in the Egyptian museum, Cairo, is an outstanding example of such work.

Lost-wax process

After about 2500 BC, the two standard methods of fabricating metal—hammering and casting—were developed side by side. The lost-wax, or cire perdue (casting with a wax mold), process was being employed in Egypt by about 2500 BC, the Egyptians probably having learned the technique from Sumerian craftsmen (see SCULPTURE, ART OF). Long after the method of casting statues in molds with cores had superseded the primitive and tedious rivetting process, the hammer continued as the main instrument for producing art works in precious metals. Everything attributable to Assyrian, Etruscan, and Greek goldsmiths was wrought by the hammer and the punch.

Embossing, or repoussé. Embossing (or repoussé) is the art of raising ornament in relief from the reverse side. The design is first drawn on the surface of the metal and the motifs outlined with a tracer, which transfers the essential parts of the drawing to the back of the plate. The plate is then embedded face down in an asphalt block and the portions to be raised are hammered down into the yielding asphalt. Next the plate is removed and re-embedded with the face uppermost. The hammering is continued, this time forcing the background of the design into the asphalt. By a series of these processes of hammering and re-embedding, followed finally by chasing, the metal attains its finished appearance. There are three essential types of tools—for tracing, for bossing, and for chasing—as well as a specialized tool, a snarling iron or spring bar, which is used to reach otherwise inaccessible areas. Ornament in relief is also produced by mechanical means. A thin, pliable sheet of metal may be pressed into molds, between dies, or over stamps. All of these methods have been known from antiquity.

Chasing. Chasing is accomplished with hammer and punches on the face of the metal. These punches are so shaped that they are capable of producing any effect—either in intaglio (incising beneath the surface of the metal) or in relief—that the metalworker may require. The design is traced on the surface, and the relief may be

obtained by beating down the adjacent areas to form the background. Such chased relief work sometimes simulates embossed work, but in the latter process the design is bossed up from the back. The detailed finish of embossed work is accomplished by chasing; the term is applied also to the touching up and finishing of cast work with hand-held punches.

Engraving. To engrave is to cut or incise a line. Engraving is always done with a cutting tool, generally by pressure from the hand. It detaches material in cutting. When pressure is applied with a hammer, the process is called carving.

Damascening and niello

Inlaying. The system of ornamentation known as damascening is Oriental in origin and was much practiced by the early goldsmiths of Damascus; hence the name. It is the art of encrusting gold wire (sometimes silver or copper) on the surface of iron, steel, or bronze. The surface upon which the pattern is to be traced is finely undercut with a sharp instrument. The gold thread is forced into the minute furrows of the cut surface by hammering and is securely held.

Niello is the process of inlaying engraved ornamental designs with niello, a silver sulfide or mixture of sulfides. The first authors to write on the preparation of niello and its application to silver were Eraclius and Theophilus, in or about the 12th century, and Benvenuto Cellini, during the 16th. According to each of these authors, niello is made by fusing together silver, copper, and lead and then mixing the molten alloy with sulfur. The black product (a mixture of the sulfides of silver, copper, and lead) is powdered; and after the engraved metal, usually silver, has been moistened with a flux (a substance used to promote fusion), some of the powder is spread on it and the metal strongly heated; the niello melts and runs into the engraved channels. The excess niello is removed by scraping until the filled channels are visible, and finally the surface is polished.

Champlevé and cloisonné

Enamelling. There are two methods of applying enamel to metal: champlevé, in which hollows made in the metal are filled with enamel; and cloisonné, in which strips of metal are applied to the metal surface, forming cells, which are then filled with enamel. (For a detailed discussion, see the section *Enamelwork* below.) (S.V.G.)

Gilding. Gilding is the art of decorating wood, metal, plaster, glass, or other objects with a covering or design of gold in leaf or powder form. The term also embraces the similar application of silver, palladium, aluminum, and copper alloys.

The earliest of historical peoples had masterly gilders, as evidenced by overlays of thin gold leaf on royal mummy cases and furniture of ancient Egypt. From early times, the Chinese ornamented wood, pottery, and textiles with beautiful designs in gold. The Greeks not only gilded wood, masonry, and marble sculpture but also fire-gilded metal by applying a gold amalgam to it and driving off the mercury with heat, leaving a coating of gold on the metal surface. From the Greeks, the Romans acquired the art that made their temples and palaces resplendent with brilliant gilding. Extant examples of ancient gilding reveal that the gold was applied to a ground prepared with chalk or marble dust and an animal size or glue.

Beating mint gold into leaves as thin as $1/280{,}000$ inch (0.00001 centimetre) is done largely by hand, though machines are utilized to some extent. After being cut to a standard $3\frac{7}{8}$ inches (9.84 centimetres) square, the leaves are packed between the tissue-paper leaves of small books, ready for the gilder's use.

The many substances to which the gilder can apply his art and the novel and beautiful effects he can produce may require special modifications and applications of his methods and materials. Certain basic procedures, however, are pertinent to all types of gilding. For example, the ground to be gilded must be carefully prepared by priming. Flat paints, lacquers, or sealing glues are used, according to the nature of the ground material. Metals subject to corrosion may be primed (and protected) by red lead or iron oxide paints. With pencil or chalk the gilder lays out his design on the ground after the ground has been prepared and is thoroughly dry. Patterns may also be laid down by forcing, or pouncing, powdered chalk or dry pigment through paper containing perforations made with pricking wheels mounted on swivels; the swivel arrangement permits the attainment of the most intricate of designs.

To create an adhesive surface to which the gold will be securely held, the area to be gilded is sized. The type of size used depends on the kind of surface to be gilded and on whether it is desirable for the size to dry quickly or slowly. When the size has dried enough so that it just adheres to the fingertips, it is ready to receive and retain the gold leaf or powder.

Application of gold leaf

Gold leaf may be rolled onto the sized surface from the tissue book. Generally, however, the gilder holds the book firmly in his left hand with the tissue folded back to expose as much leaf as is needed and detaches that amount with a pointed tool, such as a sharpened skewer. He then picks up the leaf segment with his gilder's tip, a brush of camel's hair set in a thin cardboard holder, and carefully transfers it to its place in his design. The leaf is held to the tip by static electricity, which the gilder generates by brushing the tip gently over his hair. For some gilding operations the gilder uses a cushion to hold his pieces of leaf. This is a rectangular piece of wood, about 9 by 6 inches (23 by 15 centimetres) in size, which is padded with flannel and covered with dressed calfskin; a parchment shield around one end protects the delicate leaf from disturbance by drafts of air. When the gilding is completed, the leaf-covered area should be pounced with a wad of soft cotton of surgical grade. Rubbing with cotton burnishes the gold to a high lustre. Application of a gilder's burnisher—that is, a highly polished agate stone set in a handle—also imparts a fine, high finish to the metal. Loose bits of gold, or skewings, may be removed from the finished work with a camel's hair brush.

Leaf gold may be powdered by being rubbed through a fine-mesh sieve. Powdered gold is so costly, however, that bronze powders have been substituted almost universally for the precious metal. When gold leaf is employed in the gilding of domes and the roofs of buildings, it is used in ribbon form. For finishing processes, such as burnishing and polishing, see SCULPTURE, THE ART OF. (E.L.Y.)

Western metalwork

COPPER

Copper alloys

The first nonprecious metal to be used by man was copper. But in the 4th millennium BC, Eastern craftsmen discovered that copper alloys using tin or zinc were both more durable and easier to work with, with the result that from then on the use of unalloyed copper declined sharply. Artists and craftsmen working in the West also discovered this, which is why pure copper work was relatively rare.

Pure copper is a reddish colour and has a metallic glow. When it is exposed to damp, it becomes coated with green basic copper carbonate (incorrectly known as verdigris). This patina is a drawback if copper is to be used for functional objects, for the oxide is poisonous to man. This means that utensils that come into contact with food must be lined with tin.

As copper is a relatively soft metal, it is sensitive to such influences as stress and impact. But unlike bronze it is malleable and can be hammered and chased in much the same way as silver. The surface of copper can be successfully gilded, and its reddish colouring makes the gilding seem even brighter. Because of these properties, copper was sometimes able to compete somewhat with silver.

Pure copper is not particularly good for casting, as it can easily become blistered when the gases escape. The surface of sheet copper can be engraved, however, and this technique was often used for decorating purely ornamental objects. In copperplate etching, engraving became the basis of printing. Enamel is often applied to copper, using both the champlevé and cloisonné techniques. Sheet copper was also used as a base for painted enamel. (H.-U.H.)

Antiquity. *Mesopotamia.* In the museum at Baghdad, in the British Museum, and in the University of Pennsylvania at Philadelphia are finely executed objects in beaten copper from the royal graves at Ur (modern Tall

Copper relief at al-'Ubaid

al-Muqayyar) in ancient Sumer. Outstanding is a copper relief that decorated the front of the temple at al-'Ubaid. This remarkable decoration represents an eagle with a lion's head, holding two stags by their tails. The stags' antlers—also made of wrought copper—were developed in high relief and were soldered into their sockets with lead. This relief illustrates the high level of art and technical skill attained by the Sumerians in the days of the 1st dynasty of Ur (*c.* 2650–2500 BC). In the Metropolitan Museum of Art, New York City, is a Sumerian bull's head of copper, probably an ornamental feature on a lyre, which is contemporary with the Ur finds.

The malleability of unalloyed copper, which renders it too soft for weapons, is peculiarly valuable in the formation of vessels of every variety of form; and it has been put to this use in almost every age. Copper domestic vessels were regularly made in Sumer during the 4th millennium BC and in Egypt a little later.

Egypt. From whatever source Egypt may have obtained its metalworking processes, Egyptian work at a remote period possesses an excellence that, in some respects, has never been surpassed. Throughout Egyptian history, the same smiths who worked in the precious metals worked also in copper and bronze.

Nearly every fashionable Egyptian, man or woman, possessed a hand mirror of polished copper, bronze, or silver. Copper pitchers and basins for hand washing at meals were placed in the tombs. An unusual example in the Metropolitan Museum of Art is plated with antimony to imitate silver, which was very rare in the Old Kingdom (*c.* 2686–*c.* 2160 BC). The basins and the bodies of the ewers were hammered from single sheets of copper. The spouts of the ewers were cast in molds and attached to the bodies by means of copper rivets or were simply inserted in place and crimped to the bodies by cold hammering.

(S.V.G.)

Middle Ages. *Europe.* The first well-designed copper objects to survive in the West date from about the middle of the Carolingian period, the 8th century AD. Who made them is not known, but one can assume that in the early Middle Ages they were mainly the work of monks. Indeed, the earliest copper and copper-gilt pieces are exclusively liturgical implements.

Decrees issued by the church synods held in the 8th and 9th centuries invariably expressly prohibited the use of copper and bronze for consecrated chalices, but in fact a few copper-gilt chalices like the "Tassilo Chalice" (Kremsmünster Abbey, Austria) have survived (Figure 151). The care and artistry with which they were worked and their rich engraved and niello decoration show that they were valued as highly as altar vessels made of precious metals.

Copper-gilt religious objects

From the 12th century onward, but particularly in the 13th and 14th centuries, copper-gilt chalices were relatively common, especially in Italy, where they were virtually mass-produced. Reliquaries, portable altars, shrines, and processional crosses dating from the Ottonian and Romanesque periods are also very frequently made of gilded copper and are generally decorated with enamel, niello work, or engraving or set with precious stones. One group of copper-gilt reliquaries, dating from the 12th century and after, takes the form of the head, or head and shoulders, of a saint. Others are in the shape of various parts of the body, such as an arm or a foot. These were also made in silver and in cast bronze. Ciboria (covered vessels for holding the wafers of the Eucharist), monstrances (receptacles for the Host), incense vessels, and other liturgical implements were also made in copper gilt, as well as in bronze and silver. Some of these copper-gilt implements were made as late as the Baroque period. (H.-U.H.)

Islām. The most magnificent example of Muslim enamel work in existence is a copper plate in the Tiroler Landes museum Ferdinandeum at Innsbruck, Austria, decorated in polychrome enamel, with figure subjects, birds and animals within medallions separated by palm trees and dancers (first half of the 12th century). The Mesopotamian, or Mosul, style, which flourished from the early part of the 13th century, is characterized by a predominant use of figures of men and animals and by the lavish use of silver inlay. The most famous example of figured Mosul work in Europe is the so-called Baptistery of St. Louis in the Louvre. This splendid bowl, which belongs in style to the Mosul work of the 13th century, measures five feet (150 centimetres) in circumference and is covered with figures richly inlaid with silver, so that little of the copper is visible. It is signed by the artist. (S.V.G.)

Renaissance to modern. In the second half of the 16th century, copper gilt began to be used less and less often for liturgical implements because silver had become cheaper and was therefore preferred.

In the late 16th century, Italian smiths used copper for water beakers and water jugs, decorating the surfaces with chased ornaments, whereas the rest of Europe used brass.

High-quality copper objects dating from the 17th and 18th centuries were sometimes designed and worked in the same way as the silver of the period. Most were probably trial pieces made for the guild rank of journeyman or master by silversmiths who were too poor to supply objects in precious metal. Some may have been used as workshop models or given to clients as specimen pieces.

Another type of copper vessel, known as a "Herrengrund cup," is purely ornamental and resembles the showpieces made in the 16th and 17th centuries. These mugs are made of copper that was extracted by a process known as cementation, in which water containing copper forms a deposit on iron. Production was limited to three places in the county of Sohl in Hungary. In those days the process seemed mysterious to many people; many of the inscriptions on "Herrengrund cups" refer to this mystery. The design of the beakers is modelled closely on that of silver vessels produced in southern Germany, Bohemia, and Silesia. The best examples are chased, engraved, or gilded or, more rarely, enamelled or set with precious stones. Many of them are decorated with mining scenes peopled with little figures. Most were made in the 17th century; a decline set in in the 18th century, though individual pieces continued to be made until the Empire period.

In the 17th and 18th centuries, copper enjoyed a period of relative prosperity in middle class households on the continent of Europe. For example, copper bread bins lined with tin were used; they were often richly decorated with chased motifs or brass fittings. There were also sumptuous wine coolers, cake and pudding molds, bowls, buckets, jugs, jars, screw-top flasks, sausage pans, and many other items, all polished until they shone and thus used as kitchen decorations as well as utility items.

In 18th-century Holland, jugs for tea and coffee were made in copper with a dark-brown patina and with various parts, such as the handle and the knob, in brass gilt. The sides were chased with interlaced foliage and other Rococo decorative motifs.

Sheffield plate

Copper was also the main metal used for Sheffield plate, which has a silvered surface. In 1742 Thomas Bolsover invented a method of fusing copper and silver together so that the result was highly durable, and he produced this type of silver-plated ware on a large scale. Although 18th-century England was a relatively wealthy society and solid silver utensils of all kinds were used fairly widely, the middle classes, who were not all that well off, liked to buy these implements that looked like silver yet cost only a third of the price. The makers of Sheffield plate therefore adopted the designs used for English silverware at that date, and their work was often as courtly and elegant as that of the silversmiths (Figure 152).

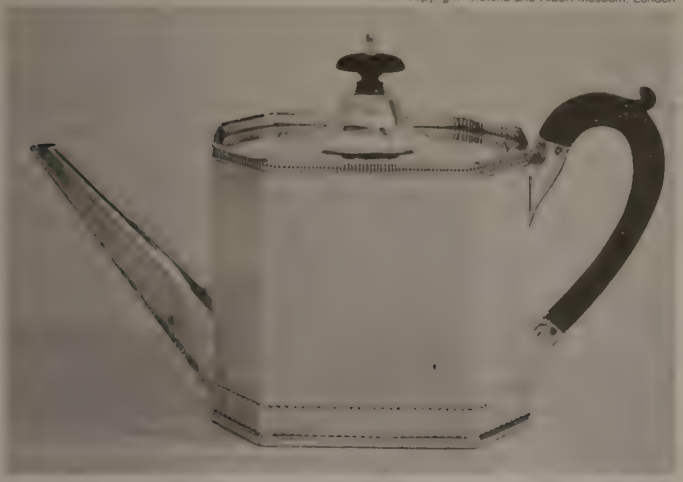

Figure 152: Sheffield plate teapot, English, late 18th century. In the Victoria and Albert Museum, London. Height 16.5 cm.

Copper ware was no longer important in the 19th century, though it was occasionally used for pieces designed to follow earlier styles or for copies of historical pieces. The method now used was electroplating, which is a purely technical process and has nothing to do with craftsmanship.

Toward the end of the 19th century, attempts were made to create a new and individual style for copper; and there were occasional signs that its inherent properties were understood and used to full effect. But there was no renaissance in the true sense of the word.

BRONZE AND BRASS

Bronze is an alloy of copper and tin. In the period of classical antiquity it had a low tin content, generally containing less than 10 percent, because tin was less common and therefore difficult to obtain. Like bronze, brass is an alloy, this time of copper plus zinc.

It is often very difficult to distinguish between bronze and brass merely by their appearance. The colour of the different alloys ranges over various shades from gold to a reddish tinge, to silvery, greenish, and yellowish shades, according to the proportions of the basic constituents. The patina on both alloys ranges from dark brown to a dark greenish tinge, particularly in the earliest pieces. Since it is often difficult to differentiate between bronze and brass with the naked eye and since metalworkers and metal casters of previous centuries did not make an express distinction between them, they will be considered together here. From a very early date bronze was used mainly for casting. Because it is so brittle, it has only rarely been hammered or chased; brass or copper were preferred for such work because they are more malleable. Down to the Middle Ages, bronze was cast by the cire perdue, or lost-wax, method. By this process, the mold can be used only once. This method of casting is the most exclusive, not only because it is the most expensive but also because it produces the finest work from the aesthetic point of view. Later, the casting process used models made up of a number of different pieces that could be taken apart and therefore re-used. These were generally made of wood and could be pressed down into a sand mold so that the shape of the object being cast emerged as a hollow. The hollow was then filled with molten bronze, which was poured in through casting ducts. When the resulting piece had been removed from the sand mold, the surface was smoothed over and the casting seams removed. The wooden model could then be used again to make as many copies as were required, which meant that economical production was possible. Brass was cast by the same methods but over and above this a process of hammering and chasing was used to fashion sheet brass. Brass platters were often decorated with relief work ornament, which was embossed from the reverse side by means of a type of die. The brass worker could also create an ornamental frieze made up of small motifs by using a series of punches made of iron. The surface of bronze or brass objects was also occasionally decorated with engraving.

Bronze casting

(H.-U.H.)

Antiquity. *Mesopotamia.* In the Metropolitan Museum of Art is the bronze sword of King Adad-nirari I, a unique example from the palace of one of the early kings of the period (14th–13th century BC) during which Assyria first began to play a prominent part in Mesopotamian history. A magnificent example of Assyrian bronze embossed work is to be seen in the gates of Shalmaneser III (858–824 BC), erected to commemorate that king's campaigns. The gates were made of wood; and the bronze bands, embossed with a wealth of figures in relief, are only about 1/16 inch (1.6 millimetres) thick. The bands were obviously intended for decoration, not to strengthen the gates against attack.

Iran. The Persian bronze industry was also influenced by Mesopotamia. Luristan, near the western border of Persia (Iran), is the source of many bronzes that have been dated from 1500 to 500 BC and include chariot or harness fittings, rein rings, elaborate horse bits, and various decorative rings, as well as weapons, personal ornaments, different types of cult objects, and a number of household vessels. Many of these objects show a decided originality in the development of the animal style (Figure 153).

Figure 153: Cast bronze finial from Luristan, 9th–8th century BC. In the Denver Art Museum, Colorado. Height 16 cm.

Egypt. The bronzes that have survived are mainly votive statues placed in the temples from the Saite to the Ptolemaic period (305–30 BC), and amuletic bronzes that were buried with the dead. In its simplest form the decoration consisted of lines, representing details of clothing, ornaments, and the like, cut in the bronze with engraving tools, sometimes also combined with gilding. A fine example of inlay work of the 22nd dynasty (945–*c.* 730 BC) is a bronze menat damascened with gold wire (Metropolitan Museum of Art).

Crete. A sword, found in the palace of Mallia and dated

to the Middle Minoan period (2000–1600 BC), is an example of the extraordinary skill of the Cretan metalworker in casting bronze. The hilt of the sword is of gold-plated ivory and crystal. A dagger blade found in the Lasithi plain, dating about 1800 BC (Metropolitan Museum of Art), is the earliest known predecessor of ornamented dagger blades from Mycenae. It is engraved with two spirited scenes: a fight between two bulls and a man spearing a boar. Somewhat later (*c.* 1400 BC) are a series of splendid blades from mainland Greece, which must be attributed to Cretan craftsmen, with ornament in relief, incised, or inlaid with varicoloured metals, gold, silver, and niello. The most elaborate inlays—pictures of men hunting lions and of cats hunting birds—are on daggers from the shaft graves of Mycenae, Nilotic scenes showing Egyptian influence. The bronze was oxidized to a blackish-brown tint; the gold inlays were hammered in and polished and the details then engraved on them. The gold was in two colours, a deeper red being obtained by an admixture of copper; and there was a sparing use of neillo.

Dagger blades

Greece. The Greeks, who learned much about metalwork from the Egyptians, excelled in hammering, casting, embossing, chasing, engraving, soldering, and metal intaglio. Among the ancients, the great emphasis of technology was on aesthetic expression, not on practical utilization. Greek coin dies rank with the finest work of this kind that the world has ever seen. Pottery and bronze hammer-and-cast work were important crafts of ancient Greece. Vases of terra-cotta were often designed to resemble those of bronze, and both kinds were widely used in antiquity. Unlike terra-cotta, which is breakable but otherwise practically indestructible, bronze is subject to corrosion; and a surviving Greek bronze vase in good condition is therefore something of a rarity. The body of the vase, which was hammered out of a sheet of malleable bronze, was usually left plain; the handles, feet, and overhanging lip, which were cast, were decorated. The applied elements were rivetted or soldered.

It was in the time of Lysippus, the distinguished sculptor who flourished about 330 BC, that the fine Greek beaten work for decoration of armour, vases, and objects of domestic use reached its perfection. It was executed by a hammer worked from behind, the outlines being afterward emphasized by chisel or punch; or metal plate was beaten into a mold formed by carving the subject in intaglio upon a resisting material. The embossed shoulder straps of a cuirass, called the "Bronzes of Siris" (4th century BC; British Museum, London), are in exceedingly high relief and are beaten into form with wonderful skill with the hammer. The relief depicts the combat between the Greeks and the Amazons.

Statuettes and monumental sculpture

Greek bronze statuettes—originally dedicatory offerings in shrines, ornamental figures on utensils, or decorative works of art—have survived in large numbers. They were usually cast solid, rarely hollow. Sometimes even large statuettes were cast solid. (The advantage of solid casting is that the mold can be used repeatedly, whereas in the hollow-casting process the mold is destroyed.) Greek bronzes were originally golden and bright, and they were often decorated with silver or niello for colour contrast. Bronze statuary hardly existed before the introduction of hollow casting, about the middle of the 6th century BC, after which bronze became the most important medium of monumental sculpture; its strength and lightness admitted poses that could not be reproduced in stone.

Etruria. The Etruscans used bronze for cast and beaten work; and although few large works remain, the museums of Europe display a marvellous variety of admirably formed small bronzes. A masterpiece of bronze Etruscan sculpture is the "Chimera" (a mythological beast with a goat's body, a lion's head, and a serpent's tail) from Arezzo, a 5th-century BC ex-voto from a sacred building, found in 1553 and partly restored by Benvenuto Cellini (Museo Archeologico di Firenze). Etruscan bronze workers produced, often for export, votive statuettes, vessels, furniture, helmets, swords, lamps, candelabra, mirrors, and even chariots. An Etruscan chariot of *c.* 600 BC in the Metropolitan Museum of Art has a body and wheels of wood, sheathing of bronze, and tires of iron, the high front embossed with archaic figures of considerable grace. The Etruscans inlaid bronze with silver and gold in a manner that proves that their skill in this mode of enrichment equalled that of the Greeks and Romans. Many delicately engraved bronze objects were made in the Latin town of Praeneste (modern Palestrina), which possessed a highly developed bronze-working industry. From Praeneste came a remarkable cylindrical container of the late 4th century BC, now in the Villa Giulia, Rome; its richly engraved surface provides a good example of the perfection of ancient drawing.

Rome. Etruscan cities, like those of Greece, were crowded with bronze statues of gods and heroes; and Rome derived its best adornment from the pillage of Etruria and then of Greece. Distinctly Roman work is hard to trace, as the conquered Greeks worked for their masters, and the Romans copied wholesale from the Greeks. Temple statues were nearly always of bronze, but after about 190 BC the metal was chiefly used for architectural decorations and portraiture. The bronze doors of the Pantheon and of the Temple of Romulus in the Roman Forum still occupy their original positions. Two bronze doors in the Lateran Baptistery are supposed to have been brought from the Baths of Caracalla by Pope Hilarius in the 5th century. Also in the Lateran church are four fine gilt-bronze fluted Corinthian columns.

Roman architectural bronze

Much Roman small work was exceedingly fine, though it is generally conceded that Roman productions are less aesthetically attractive than those of the Greeks. Pompeii and Herculaneum were essentially Greek towns, and the many beautiful bronzes in the Museo e Gallerie Nazionali di Capodimonte, Naples, collected from the ruins of private houses there, are of Greek workmanship. These included statuettes, mirrors, and all kinds of bronze work useful in a house. Many of these pieces were originally attached to pieces of furniture.

During the closing years of the republic, brass, produced by what came later to be known as the calamine (zinc-carbonate) method, became an important material for the first time. Its various uses included parade armour, as may be seen in a Roman embossed brass helmet in the Castle Museum, Norwich, England.

Teutonic tribes. The Teutonic tribes who conquered and divided the Roman Empire were little versed in the monumental arts and unskilled in figure representation; but in metalworking, in the making of weapons and other utilitarian objects, and in the delicate ornament of the goldsmith's art they excelled. They were among the earliest in Western Europe to develop the use of enamel decoration on bronze in the champlevé technique.

Middle Ages: Byzantine Empire. Syria, Egypt, and Anatolia were first the teachers and then the rivals of Constantinople (Istanbul). The fusion of antique and Eastern elements resulted in the Byzantine style, the great period of which dates from the 9th to the end of the 12th century. The extensive use of embossed work, with filigree, cabochon gems, and small plaques of enamel, may be seen in both the East and the West during the early Middle Ages. The most conspicuous examples of large Byzantine metalwork are bronze church doors inlaid with silver. Many objects are still preserved in various European treasuries, which were enriched by the spoils of the sack of Constantinople in 1204. Venice, in the Treasury of St. Mark's, has an unrivalled series of Byzantine chalices, bookbindings, and other treasures of metalwork; but it is in Kiev, Moscow, and Leningrad that broadly representative series of all the categories of Byzantine artistic production may be found.

The art of bronze casting had been preserved in the Byzantine Empire. The first bronze doors to be made after the art had died out in Rome were those for Hagia Sophia at Constantinople, which bear the date 838; the panels, with monograms and other ornament damascened in silver, are framed in borders cast in relief and enriched with bosses and scrolls, the whole in an admirable style. Two sets of doors in St. Mark's, Venice, of Greek workmanship and considerable but uncertain antiquity, are supposed by some to have been removed from St. Mark's at Alexandria. Next in date among surviving doors of

Bronze doors of Hagia Sophia

Byzantine workmanship is a series ordered by the Pantaleone family (about 1066–87) and destined for cities in southern Italy—Amalfi, Trani, Salerno, Canosa di Puglia, and Monte Sant'Angelo. (S.V.G.)

Middle Ages: Islām. Animals in the Sāsānian style—lions, dragons, sphinxes, peacocks, doves, cocks, and the like—were cast in bronze in three dimensions and served, like their ceramic counterparts, as basins, braziers, and so on. They were particularly sought after in the later Abbāsid, Fātimid, and Seljuq periods, and from Egypt they became prototypes of similar European forms. It was the Seljuqs, apparently, who introduced a round bronze mirror, the reverse of which shows in low relief two sphinxes face to face, surrounded by a twined pattern, or two friezes with the astrological symbols of the seven chief heavenly bodies (Sun, Moon, and the five nearest planets) and the 12 signs of the zodiac, surrounded by a band of script; this goes back ultimately to Chinese origins.

Early vessels, such as mugs, were ornamented with animals in low relief, but engraving quickly supplanted this. Under the later Seljuqs (particularly the Artuqid atabegs of Mosul) and the Mamlūks, engraving became almost the only form of decoration, but only to serve as a basis for the yet richer technique of inlaying, or damascening: small silver plates and wires, themselves delicately engraved, were hammered into the ribs and surfaces, which were hollowed out and undercut at the edges.

Engraving and inlaying

In place of this, in an Artuqid bowl in the provincial museum at Innsbruck the spaces are filled in with cellular enamel. This was a method of evading the prohibition of precious metals, just as gold lustre was in pottery. The ornament consisted of friezes and medallions in lattice work and arabesque work, the interstices being filled with figures of warriors, hunters, musicians, animals, and astrological symbols. These were superseded later by Mamlūk coats of arms and inscriptions. In the 15th century the technique was imported from Syria to Venice, where productions of the same kind, *alla damaschina* or *all'azzimina*, were made right into the 16th century by Islāmic masters and were in great demand. In the East the process is still common, but both technically and artistically it has decayed.

In the 15th century there was a renaissance of pure metal engraving, but the design—inscriptions and arabesques in the Tīmūrid and Ṣafavid styles—was not cut into the material but left free in the manner of a relief, the background being etched in black. Decoration was applied to bowls, basins, mugs, vases, mortars, braziers, warming pans, candlesticks, smoking utensils, inkstands, jewel cases, Qur'ān holders, and mosque lamps. These are generally in the simplest possible forms—spherical, cylindrical, prismatic; the subjects include motifs of vegetation and animal life, the former mainly in the necks and feet of vessels, the latter for handles and ears, feet, and sometimes small spouts. (H.Go.)

Revival of the art of bronze casting

Europe from the Middle Ages. After several centuries of artistic decline, the art of bronze casting was revived in *c.* 800 by Charlemagne, who had monumental bronze portals made for the Palatine Chapel in his residence in Aachen, with bronze grilles placed inside it. The artists, who probably came from Lombardy, followed the styles of classical antiquity.

For many centuries the Christian Church remained the bronze caster's chief patron. Like the stonemasons, who also were heavily patronized by the church, they joined together to form associations, or foundries. These casting foundries hired themselves out to the large ecclesiastical building sites. They cast bells—almost every church had at least one bell—and monumental doors decorated with relief work; for instance, doors for Mainz (*c.* 1000) and Hildesheim (1015) cathedrals, for the cathedrals at Gneissen and Augsburg (11th century), and for St. Zeno Maggiore in Verona (12th century). They also made large fonts, the most famous being the one made by Renier de Huy in 1107–18 for the church of Notre Dame aux Fonts in Liège (now in the church of St. Barthélemy in Liège). The Dinant workshops, which formed the main centre for bronze casting in the Meuse district in the Middle Ages, specialized in what are known as "eagle lecterns." These are book stands with ornamental pedestals, with the panel supporting the enormous missals taking the form of the outspread wings of an eagle, a griffin, or a pelican. The earliest documented eagle lectern was made in 965, but the earliest example to have survived dates from 1372. It was made by Jean Joses of Dinant for the Church of Our Lady at Tongeren (Tongres), near Liège.

Records show that from the 11th to the 15th century there were more than 50 monumental seven-branched candlesticks (menorah) in various churches in Germany, England, France, Bohemia, and Italy, though only a few of these have survived. Documents relating to the Carolingian period speak of monumental bronze crucifixes and statues of the Virgin and of the saints, though the earliest surviving statues date from the 11th century; the crucifix in the abbey church at Werden, for example, dates from *c.* 1060 and was probably cast in a foundry in Lower Saxony.

Among the most outstanding examples of figurative bronze sculpture dating from the Romanesque period are a group of reliquaries designed in the shape of heads or heads and shoulders or occasionally arms, hands, or feet, according to the type of relics they contain. They were made in Lower Saxony or in France.

A few large chandeliers have survived from the 11th and 12th centuries, representing a sort of halfway stage between sculpture and functional objects. A far larger number are known to have existed from documents and contemporary accounts, but these have disappeared over the centuries. Examples from Germany, the southern half of the Low Countries, and France have survived or are documented. Romanesque chandeliers are always designed in the form of a crown. Candleholders, with architectonic structures and figures placed in between them, project from the crown.

Besides the monumental bronzes that have survived from the 8th to the 12th century, there are also a number of smaller pieces, such as processional crosses, altar crucifixes, chests, reliquaries, and similar articles. Another group of liturgical objects consists of candlesticks used to adorn altars. Their design often shows a wealth of invention, and they are decorated in the most sumptuous fashion. There was yet another group of candlesticks, which were secular in nature, that embodied the ideal of chivalry. They are cast in the shape of human figures: an armed warrior on horseback bearing a candleholder with a spike on which the candle is placed; a kneeling page in court dress holding a candle socket in his outstretched hands; or Samson perched on the lion's back, brandishing a candleholder. These candlestick figures are rare and precious examples of courtly life in the Romanesque period in Germany, France, England, and Scandinavia. Even at that time they were thought of as rare, deluxe articles within the reach of only a few privileged people.

Candlesticks

Figure 154: Bronze aquamanile in the shape of a lion, German, 13th century. In the Metropolitan Museum of Art, New York. Height 26.7 cm.

Toward the end of the Romanesque period a simpler type of candlestick appeared, mainly intended for religious purposes, though they were found in private homes as well. They are circular, with a round base, a slender column-like shaft, and a large grease pan with a spike for the candle. This design exercised a strong influence throughout the Gothic period and right down to the Baroque period, though it varied considerably over the years according to the styles then prevailing.

Aquamaniles and basins

Some of the finest bronze articles of the High Middle Ages were modelled on Oriental pieces brought back from the Holy Land by the crusaders. They are known as aquamaniles, a type of ewer used for pouring water for washing one's hands. Made by bronze casters in France, Germany, England, and Scandinavia, they are usually in the shape of lions—symbols of valour, pride, physical strength, and power (Figure 154). Also common are those shaped like knights in armour, with a wealth of courtly detail that was obviously popular. A few aquamaniles are in the shape of winged dragons, doves, cockerels, centaurs, or sirens; but such designs are rare. Christian themes, too, played a part, some examples depicting Samson overcoming the lion with his knee planted on its back. The golden age of these vessels was the 12th, 13th, and 14th centuries. The end of the age of chivalry also saw a decline in such work, for the emergent bourgeoisie found other ways of marking the ceremony of hand washing.

Basins were also needed for washing one's hands; they are often mentioned in medieval documents, where they are referred to as *bacina, pelves,* or *pelvicula.* The majority of these bowls—which date from the 12th and 13th centuries—have been found in the cultural area that extends from the Baltic down to the Lower Rhine district and across to England. Because this area was once dominated by the Hanseatic League (a commercial association of free towns), the basins are known as Hanseatic bowls. They are round, some being more convex than others; and the inside is engraved with scenes from classical mythology, with themes from the Old and New Testaments and the legends of the saints, or with allegorical figures personifying the virtues and the vices, the liberal arts, the seasons, and so on. Hanseatic bowls were probably made in the bronze-casting centres where candlesticks and aquamaniles (and indeed all medieval cast bronze) were made: in the Meuse district and Lorraine, in Lower Saxony and the Harz Mountains, and also in England. The decoration on these bowls may have been added elsewhere.

Alinari—Art Resource

Anderson—Alinari from Art Resource

In the Romanesque period and later, in the Gothic period, the churches and their patrons were still the bronze caster's main clients, ordering both functional objects and decorative pieces. Bronze fonts were relatively common in the 14th and 15th centuries, particularly in churches in northern Germany. Another common item, which was made mainly in England and in the Netherlands, was a large brass tombstone decorated with engraving. Other objects included door fittings, candlesticks, candelabra, chandeliers, pulpits, and sculptured tombs portraying the deceased.

Italy. Until the 12th century in Italy the art of bronze casting had been virtually neglected since the period of classical antiquity, when it had been a flourishing industry. A few churches in Italy have bronze doors inlaid with Byzantine niello work made by Byzantine craftsmen in the 11th and 12th centuries. The same technique was used by Bohemond I of Antioch for a bronze door at Canosa (1111) and by Oderisius of Benevento when casting a pair of doors for Troia Cathedral in 1119 and 1127. In the

Byzantine influence in Italy

second half of the 12th century, however, Barisano da Trani made relief door panels for churches in Astrano, in Ravello (a town near Amalfi), and in Monreale. Bronze relief doors were also made in the 12th century for S. Paolo fuori le mura in Rome and for churches in northern Italy (S. Zeno Maggiore in Verona; St. Mark's in Venice) and Tuscany (Pisa and Monreale, by Bonanno of Pisa) and in the 13th century for the Baptistery in Florence, by Andrea Pisano.

Lorenzo Ghiberti's doors for the Baptistery in Florence, made in 1403–24 and 1425–52 (Figure 155), marked the beginning of a golden age of bronze casting in Florence that lasted throughout the Renaissance and right down to the Baroque era. Whereas bronze sculpture had been relatively rare before the 15th century, many Italian artists of the Renaissance now designed cast bronze statues, statuettes, reliefs, and various objects in the shape of human figures. Among the sculptors who worked in full-scale bronzes were Lorenzo Ghiberti, Donatello (Figure 156), Andrea del Verrocchio, Antonio Pollaiuolo, and Lucca della Robbia. Besides large-scale cast-bronze work there were also small figures, statuettes, busts, plaques, and functional objects such as candelabra, mortars, candlesticks, and inkwells. Dating from the middle of the 15th century onward, they are characterized by rich figural and ornamental design. Their style influenced work produced in northern Europe, particularly in the 16th century.

In the first half of the 16th century, bronze casting declined somewhat in Italy, though it found a new lease on life in the middle of the century and, indeed, became even more important than before. Benvenuto Cellini and Giovanni da Bologna are two of the most famous artists of this period. Cellini designed a number of statues, one of the best known being his "Perseus" in the Loggia dei Lanzi in Florence, as well as portrait busts, reliefs, and smaller articles in bronze. Giovanna da Bologna, a Fleming by birth, was active in Rome and Florence, where he made fountains, equestrian monuments, allegorical figures, crucifixes, statuettes, groups of figures, animals, and many other objects. He founded a school of sculptors who were influenced by his work for many years. Many other bronze sculptors were active in the 16th and 17th centuries, notably in Venice, which was a particularly fruitful area for bronze casting, and at a school in Padua led by Andrea Riccio (Briosco). Italian bronze casters worked abroad as well as in their homeland, working on commission for foreign potentates, mainly in France and England.

In the 16th century, beautifully made bronze pieces, which were very much more than functional objects, played an important part in the art of the bronze caster. For instance, sumptuous mortars were designed and made by artists whose names have been handed down to posterity, such as Cavadini, Lenotti, Juliano da Navi, Alessandro Leopardi, Antonio Viteni, and Crescimbeni da Perugia. Elaborate brass dishes were made in Venice, under the influence of Eastern art (to which Venice had always been very receptive); indeed, the first people to produce these large dishes with engraved motifs were Islāmic artists who had settled in the town, though the local artists soon adopted both their style and their technique.

Germany and the Low Countries. Unlike their Italian counterparts, 15th-century bronze artists in Germany and the Low Countries were still under the spell of Gothic art, and ecclesiastical implements predominated.

The Dinant workshops, in the Meuse district, continued to dominate production until well past the middle of the 15th century, just as they had since the days of Charlemagne. But when Philip III the Good, duke of Burgundy, laid siege to the town in 1466, then took it by storm and eventually completely destroyed it, the bronze casters who survived moved elsewhere, settling mainly in the Low Countries. As a result, from that date onward the trade enjoyed a sudden upsurge in Brussels and Namur, in Tournai and Bruges (Flemish Brugges), in Malines (Flemish Mechelen), Louvain (Flemish Leuven), and Middelburg. There was another centre of the bronze trade in Lower Saxony, since the mines in the Harz Mountains produced a generous supply of copper and calamine. The chief bronze-working towns in this area were Hildesheim, Goslar, and Minden. In the 16th century, a period when trade and commerce were developing very rapidly in Germany, the bronze-casting trade was no longer compelled to function close to the place where the raw material was extracted. Thus, Nürnberg, at this time the most powerful and lively town in Germany, not only traded in copper, bronze, and brass but also soon allowed its bronze casters and metalworkers to develop a flourishing industry. Brass articles from Nürnberg became famous throughout the world.

Nürnberg brass work

The earliest documented brass workers were those known as "basin-beaters" (*Beckenschläger*), who were first referred to as such in 1373. They made bowls and dishes with various types of relief decoration on the bottom. In the late Gothic period, religious themes were very popular for this decoration and were more common than secular images (Figure 157). During the Renaissance, beginning

Figure 157: Brass dish with embossed Annunciation scene, German c. 1500. In the Victoria and Albert Museum, London. Diameter 45 cm.

in about 1520, the design changed; instead of deep bowls there were large, flat dishes with decoration that consists of purely ornamental motifs or friezes as well as scenes and figures. The decoration includes the typically Gothic "fishbladder" design and also interlaced motifs and bands of lettering. The trade of the basin beaters continued to flourish in Nürnberg down to about 1550, when a decline set in, culminating in its eventual collapse just before the Thirty Years' War in 1618. The reason for this decline may have been the emergence of what is known as display pewter (see below *Pewter*), which, from about 1570 onward, swept the wealthy bourgeoisie market.

Until the Gothic era, bronze chandeliers were made solely for the churches; it was not until the 15th century that people began to consider lighting their homes by means of a central source of light hanging from the ceiling. In the Low Countries, one of the centres of the art of bronze casting, a type of chandelier was developed at this time that remained standard for many years. It is a type of hoop with a shaft, made up of a molded vertical centrepiece and a series of curving branches bearing drip trays and spikes. The arms, or branches, are decorated with tracery, foliage scrolls, and other motifs characteristic of the late Gothic style (Figure 158). In the middle of the 16th century, the central shaft took on the shape of a spherical baluster, with a large sphere jutting out just below the point where the curving arms branch off. This design continued to predominate in the Baroque period and is found as late as the 18th century. Because chandeliers of this type were most common in the Low Countries, one can assume that they originated there and were produced in large numbers and that they spread to England and Germany. Another centre was in Poland, presumably because brass founders had moved there from Nürnberg.

Besides these chandeliers—which until the 19th century

Figure 158: Bronze chandelier, Dutch, 15th century. In the Rijksmuseum, Amsterdam. Height 1.09 m.
By courtesy of the Rijksmuseum, Amsterdam

were exclusive to court circles, the aristocracy, and the upper ranks of the bourgeoisie—there were also candlesticks. Their design was a later development of that used for altar candlesticks. The principle of a disk-shaped foot and a baluster shaft with a spike on top remained standard from the Middle Ages well into the 19th century, though the design of the individual components was affected by the styles current in any particular period. In Dinant and Flanders in the 15th century, for instance, the shaft began to be fashioned into the shape of a human figure. This style also became popular in Germany.

Whereas bronze sculpture reached its peak in Italy in the 15th century, monumental bronze figures were still rare in northern Europe at this time. Thus, the full-length equestrian statue of St. George (1373) on Hradčany Castle in Prague, which was cast by Martin and Georg von Klausenberg, did not set a trend, though rich figure decoration is often found on large fonts dating from the 13th to the 15th century. Engraved tombstones and entire tombs based on earlier traditions continued to be made until the late Gothic era (the beginning of the 16th century), as did tabernacles and lecterns.

The intellectual content of the Renaissance and the styles it engendered entered the world of the northern sculptors in the second decade of the 16th century. The Nürnberg workshop run by the Vischer family, which had been flourishing since the 15th century, continued to work in the late Gothic style until it had completed the St. Sebald's Shrine (1516), but shortly after this the style and intellectual concepts current in Italy were adopted by bronze casters in northern art centres as well. Small-scale bronze sculpture was particularly popular at this time, though some workshops were still casting monumental bronzes as late as the 18th century. (H.-U.H.)

England. Casting in bronze reached high perfection in England during the Middle Ages. The most remarkable of the sanctuary rings, or knockers, that exist at Norwich and elsewhere is that on the north door of the nave of Durham cathedral, from the first half of the 12th century. The Gloucester candlestick, in the Victoria and Albert Museum, London, displays the power and imagination of the designer as well as an extraordinary manipulative skill on the part of the founder. According to its inscription, this candlestick, which stands about two feet (60 centimetres) high and is cast in bell metal and gilded, was made for Abbot Peter (the cathedral was originally an abbey church), who ruled early in the 12th century. While the outline is carefully preserved, the ornament consists of a mass of figures of monsters, birds, and men, mixed and intertwined to the verge of confusion. As a piece of casting, it is a triumph of technique.

The Gloucester candlestick

There remain in England 10 effigies cast in bronze over a period of two centuries (1290–1518), among them some of the finest examples of figure work and metal casting to be found in Europe. In several instances, particulars for the contracts of the tombs survive, together with the names of the artists who designed and made them. The earliest examples are the effigies of Queen Eleanor, wife of Edward I (1290), and that of Henry III (1291), both in Westminster Abbey (Figure 159). They are the work of William Torel, goldsmith of London; and it is evident that they are the first English attempt to produce large figures in metal. Torel cast his large figures by the same process (lost-wax) he had employed for small shrines and images.

Monumental brasses were exceedingly numerous in England, where some 4,000 still exist. From the 13th through the 16th centuries, in France, northern Germany, Belgium, and particularly England, it became the vogue to set into the stone slab covering a floor tomb a brass plate engraved with the figure of the deceased. The art began in Flanders and Germany, and many of the English brasses were of foreign origin; in some cases, brass sheets were imported and engraved by English artists. The manufacture of unornamented brass plates centred chiefly at Cologne. The oldest English brass in existence is that of Sir John D'Abernon (died 1277) at Stoke d'Abernon, Surrey. Traces can still be seen in many brasses of the colours that originally enlivened them. (S.V.G.)

France. In France, bronze was common from the late

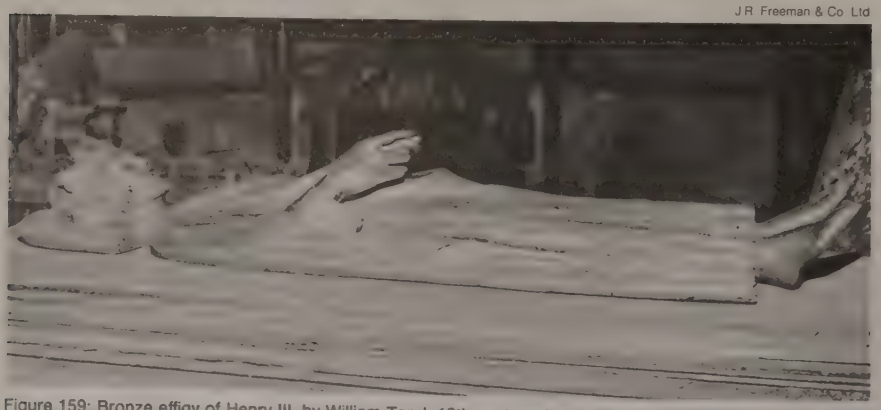

Figure 159: Bronze effigy of Henry III, by William Torel, 13th century. In Westminster Abbey, London. Length 1.50 m.

French ormolu

16th century through the 17th, 18th, and 19th centuries, and it is still popular with French sculptors today. Eighteenth-century artists made use of ormolu, or fire gilding, for bronze articles such as candlesticks, brackets, and mounts for furniture. This tradition continued in France and, to a lesser extent, in the areas under French influence, until the Empire period in the early 19th century. Subdued classical designs executed in simple brass or in bronze, generally ungilded, are typical of the period following the reign of Napoleon.

The second quarter of the 19th century and, with it, the onset of industrialization, brought about a decline in bronze casting, as it did in all spheres of craftsmanship. The age of steel production now began. At the end of the 19th century, during the Art Nouveau period, attempts were made to revive the craft of casting bronze articles; but these did not have any lasting success. Bronze continued to be used by a few individual sculptors, however, throughout the 19th century and into the present day.

(H.-U.H.)

SILVER AND GOLD

Antiquity. *Pre-Mycenaean.* Gold and silver and their natural or artificial mixture, called electrum or white gold, were worked in ancient Greece and Italy for personal ornaments, vessels, arrows and weapons, coinage, and inlaid and plated decoration of baser metals.

Aegean lands were rich in precious metals. The considerable deposits of treasure found in the earliest prehistoric strata on the site of Troy are not likely to be later than 2000 BC. The largest of them, called Priam's Treasure, is a representative collection of jewels and plate. Packed in a large silver cup were gold ornaments consisting of elaborate diadems or pectorals, six bracelets, 60 earrings or hair rings, and nearly 9,000 beads. Trojan vases have bold and simple forms, mostly without ornament; but some are lightly fluted. Many are wrought from single sheets of metal. The characteristic handle is a heavy rolled loop, soldered or rivetted to the body. Bases are sometimes round or pointed, sometimes fitted with separate collars but more often slightly cupped to make a low ring foot. One oddly shaped vessel in gold is an oval bowl or cup with a broad lip at each end and two large roll handles in the middle. The oval body has Sumerian affinities. A plain, spouted bowl in the Louvre is a typical specimen of goldsmith's work from pre-Mycenaean Greece. The scarcity of precious metals points to lack of wealth as prime cause of the artistic backwardness of these regions. Silver seems to have been more plentiful in the Greek islands; but only a few simple vessels, headbands, pins, and rings survive.

Trojan vases

Minoan and Mycenaean. A profusion of gold jewelry was found in early Minoan burials at Mókhlos and three silver dagger blades in a communal tomb at Kumasa. Silver seals and ornaments of the same age are not uncommon. An elegant silver cup from Gournia belongs to the next epoch (Middle Minoan I, *c.* 2000 BC). Numerous imitations of its conical and carinated (ridged) form in clay and of its metallic sheen in glazed and painted decoration prove that such vessels were common. Minoan plate and jewelry are amply represented in the wealth of mainland tombs at Mycenae and Vaphio. The vases from Mycenae are made indifferently of silver, gold, and bronze; but drinking cups, small phials, and boxes are generally made only of gold; and jugs are made of silver. Much funeral furniture is gold, notably masks that hid the faces or adorned the coffins of the dead. It has been thought that small gold disks, found in prodigious quantities (700 in one grave), were nailed on wooden coffins; but they may have been sewn on clothes. They are impressed with geometrical designs based on circular and spiral figures, stars and rosettes, and natural forms such as leaves, butterflies, and octopods. Smaller bossed disks bearing similar patterns may be button covers. Models of shrines and other amulets are also made of gold. A splendid piece of plate is a silver counterpart of a black steatite, or soapstone, libation vase from Knossos in the form of a bull's head, with gold horns, a gold rosette on the forehead, and gold-plated muzzle, ears, and eyes. (The gold here and in other Mycenaean plating is not laid on the silver but on inserted copper strips.)

Funeral furniture

Gold cups from Mycenae are of two main types: plain curved or carinated forms related to the silverware and pottery of Troy and embossed conical vessels of the Minoan tradition. Some of the plain pieces, such as the so-called Nestor's cup (Figure 160), have handles ending in animals, which bite the rim or peer into the cup. The em-

Alison Frantz

Figure 160: Mycenaean gold cup, the so-called Nestor's cup, decorated with birds on handles, from the royal graves at Mycenae, Greece, *c.* 1600–1500 BC. In the National Archaeological Museum, Athens. Height, excluding handles, 14.5 cm.

bossed ornament consists of vertical and horizontal bands of rosettes and spiral coils and of floral, foliate, marine, and animal figures. The designs are beaten through the walls and are consequently visible on the insides of most of the vessels; but the finest examples of their class, two gold cups from the Vaphio tomb near Sparta, have a plain gold lining that overlaps the embossed sides at the lip. The reliefs on the Vaphio cups represent men handling wild and domesticated cattle among trees in a rocky landscape. (Steatite vases carved with similar pictorial reliefs were evidently made to imitate embossed gold.) The handles show the typical Minoan form: two horizontal plates rivetted to the body at one end and joined at the other by a vertical cylinder.

Weapons

Cretan and mainland tombs have produced many examples of weapons adorned with gold. Modest ornaments are gold caps on the rivets that join hilt and blade, but the whole hilt is often cased in gold. An example from Mycenae has a cylindrical grip of openwork gold flowers with lapis lazuli in their petals and crystal filling between them; the guard is formed by dragons, similarly inlaid. The most splendid Mycenaean blades are bronze inlaid with gold, electrum, silver, and niello. Here again the work is done on inserted copper plates. This kind of flat inlay seems to have been originally Egyptian; it occurs on daggers from the tomb of Queen Aah-Hotep, which are contemporary with the Mycenaean (*c.* 1600 BC). Moreover, it is significant that two of the Mycenaean designs have Egyptian subjects (cats hunting ducks among papyrus clumps beside a river in which fish are swimming), though their style is purely Minoan. Another blade bears Minoan warriors fighting lions and lions chasing deer. A dagger from Thira has inlaid ax heads; one from Argos, dolphins; and fragments from the Vaphio tomb show men swimming among flying fish. These are masterpieces of Minoan craftsmanship. In the long, subsequent decadence of the Mycenaean age, however, there seems to have been no invention, and later pieces of goldsmiths' work repeat conventional forms and ornaments. (E.J.F./M.C.R.)

Iran. The Persians have been skillful metalworkers since the Achaemenid period (559–330 BC), when they were already acquainted with various techniques such as chasing, embossing, casting, and setting with precious stones. Statuettes of gold and silver are known from the 5th century BC, and vessels of silver and gold from this time

take the form of phials, conical cups, vases, and rhyta (drinking cups in the shape of an animal's head). The Oxus treasure in the British Museum and the Susa find in the Louvre, Paris, are good examples of such work. During the Parthian period (247 BC–AD 224), silverwork and goldwork was strongly influenced by Hellenistic predilection for richly decorated bowls and dishes. The zenith of old Iranian metalwork, however, was reached during the Sāsānid period (AD 224–651), when craftsmen achieved great variety in shape, decoration, and technique. Drinking vessels (stem cups and cups with handles), ewers, oval dishes, platters, and bowls are the dominant forms; hunting scenes, drinking scenes, and animals are represented

Sāsānid craftsmanship

in high relief (Figure 161). The patterns were cut out of solid silver or made separately in sheets and then soldered to the vessel. From this time onward cloisonné enamel was used for jewelry. (B.V.Gy.)

Greek and Etruscan. The period of transition from the Bronze to the Iron Age, when Aegean external relations were violently interrupted, was not favourable either to wealth or art; and the only considerable pieces of plate that have come from Greece are embossed and engraved silver bowls made by Phoenicians. Most of them bear elaborate pictorial designs of Egyptian or Assyrian character and are evidently foreign to Greece; but some simpler types, decorated with rows of animals in relief or wrought in the shape of conventional flower bowls, can hardly be distinguished from the first Hellenic products. A severe and elegant silver bowl in the Metropolitan Museum of Art represents the flower type in its finest style. It is cast and chased and probably belongs to the 5th century BC.

Silver vases and toilet articles have been found beside the more common bronze in Etruscan tombs; for example, a chased powder box of the 4th century BC in the Metropolitan Museum of Art. Bronze reliefs of an archaic chariot in the same collection have their opulent counterparts in some hammered silver and electrum fragments in London, Munich, and Perugia. The electrum details are attached with rivets.

Roman silver relief

Roman. About the 4th century BC, the fashion of ornamenting silver vessels with relief was revived; and this type of work, elaborated in the Hellenistic Age and particularly at Antioch and Alexandria, remained the usual mode of decoration for silver articles until the end of the Roman Empire.

The scholar Pliny the Elder (1st century AD) names Greek silversmiths whose work was valued highly at Rome and laments the disappearance of the art in his own day. He must refer only to its quality, for Roman silverware has been abundantly preserved. Many rich hoards in modern collections were buried by design during the calamitous last centuries of the ancient world; and the most sumptuous, the Boscoreale treasure (mostly in the Louvre), was accidentally saved by the same volcanic catastrophe that destroyed Herculaneum and killed Pliny in AD 79 (Figure 162). A slightly smaller hoard found at Hildesheim (now in Berlin) also belongs to the early empire. The acquisition and appreciation of silver plate was a sort of cult in Rome. Technical names for various kinds of reliefs were in common use (*emblemata, sigilla, crustae*); weights were recorded and compared and ostentatiously exaggerated. Large quantities of bullion came to Rome with the spoils of Greece and Asia in the 2nd century BC; and Pliny says that even in republican times there were more than 150 silver dishes of a hundredweight apiece in the city. (Weights of vessels are often marked on their bases.)

Cups and jugs

Cups and jugs of Augustan style are usually covered with ornament in high relief. The subjects are very diverse: historical, mythological, and mystic scenes, formal and naturalistic designs of flowers and foliage, graceful studies of animals and birds. Some cups and jugs have conventional fluting, petals, or gadroons (ornamental bands embellished with continuous patterns); Bacchic masks; and embossed or engraved wreaths, gilt or inlaid with niello. Silver and niello inlay was commonly applied to bronze plates. A singular type of silver bowl (*patera clipeata*) has a central ornament in high relief or even in the round; the ornament frequently contains a portrait bust. In time the ornament was restricted; and later Roman plate is plain with narrow border friezes, small central medallions, and handles embossed in low relief. One of the very few gold pieces that survive, a shallow bowl found at Rennes (Bibliothèque Nationale), is exceedingly elaborate. It measures 10 inches across and weighs 46 ounces. The central medallion and its surrounding frieze contain scenes of a drinking contest between Bacchus and Hercules; between the frieze and the edge of the bowl is a row of 16 gold coins, each framed in a foliate wreath. The coins range from Hadrian to Caracalla. In the same collection are several examples of very large silver plates (*clipei* or *missoria*), in which the whole field is embossed with mythological or historical subjects. The largest (called the Shield of Scipio) is 28 inches in diameter and weighs 363 ounces.

(E.J.F./M.C.R.)

Early Christian and Byzantine. The earliest Christian silverwork closely resembles the pagan work of the period in its naturalistic grace, ornament, and use of the traditional techniques of embossing and chasing. Even the subject matter is sometimes classical: the late 4th-century

marriage casket of Projecta and Secondus (Figure 163), part of the Esquiline treasure found at Rome (British Museum), is decorated with pagan scenes; and only the inscription shows that it was made for a Christian marriage. Among the few pieces with Christian subjects are small Roman cruets (condiment bottles) from Taprain, Scotland (Royal Scottish Museum, Edinburgh, and the British Museum), and a small pyx (casket for the reserved Host) from Pola, Yugoslavia (Kunsthistorisches Museum, Vienna).

Most of the silver of the latter part of the period has been found in the Christian East—in Syria, Egypt, Cyprus, Asia Minor, and Russia—and is mostly "church" plate (chalices, censers, candlesticks, and bowls and dishes probably used to hold the eucharistic bread). Secular plate was also decorated with religious subjects—for example, dishes depicting the life of David (Cyprus Treasure, Cyprus Museum, Nicosia, and Metropolitan Museum); both dishes and vessels were produced with pagan subjects—for example, the Concesti amphora and the Silenus Dish (both in the Hermitage, Leningrad). The figure style is often harder and flatter than previously, characterized by strictly frontal positions and symmetry. The techniques of chasing and embossing still predominated, but abstract patterns and Christian symbols inlaid in niello were used increasingly. The appearance of imperial "control stamps," early forerunners of hallmarks, show most of this material to be of the 6th and 7th centuries. It is not known which cities were important centres of production; but the Eastern capital, Constantinople, must have been foremost among them.

Religious decoration

Of work in gold of the earliest Christian period, only personal jewelry has survived; but from the 6th and 7th centuries onward other pieces are also extant. Among the most important of the latter are votive crowns and crosses offered to churches in Spain and Italy by royal patrons. The finest of these pieces are those found in Guarrazar in Toledo Province (National Archaeological Museum, Madrid, and Musée de Cluny, Paris), inlaid with garnets and jewels; the cross of King Agilulf (cathedral of Monza, Italy); and a pair of gold book covers inscribed by Queen Theodolinda (cathedral of Monza, Italy). The book covers are set with pearls, gems, and cameos and decorated with gold cloisonné work inlaid with garnets, a popular style among the Germanic peoples. Inlaid cloisonné jewelry reached an especially high standard of workmanship in Britain, as is shown by a purse lid, a sword, and jewelry from the cenotaph (monument honouring a dead person whose body lies elsewhere) to a 7th-century East Anglian king discovered at Sutton Hoo, Suffolk (British Museum). Major works in silver and gold were also produced in the northern Hiberno-Saxon school and in the service of the Celtic Church; work in precious metal, such as the buckle on the Moylough belt reliquary and the Ardagh Chalice in the National Museum of Ireland, Dublin, displays a masterly synthesis of the northern arts and humanist Mediterranean tradition.

Middle Ages. *Carolingian and Ottonian.* The earliest works of the Carolingian renaissance, made in the last quarter of the 8th century, resemble Hiberno-Saxon art of the 8th century in their abstract treatment of the human figure, their animal ornament, and their use of niello and "chip-carving" technique; examples are the Tassilo Chalice (Kremsmünster Abbey, Austria) and the Lindau Gospels book cover (Pierpont Morgan Library, New York City). From about 800 onward, however, the influence of the Mediterranean tradition gained strength at Charlemagne's court at Aachen and later spread through the whole empire. Triumphal arches (now lost) given by the Emperor's biographer Einhard to Maastricht cathedral were typical of this movement; miniature versions nine inches (22 centimetres) high of great marble triumphal arches of antiquity, they were embossed in silver with Christian subjects. The bulk of work in precious metals that survives from the Middle Ages is ecclesiastical: golden altars, like that of S. Ambrogio in Milan (*c.* 850), where scenes from the life of Christ and St. Ambrose are framed by panels of cloisonné enamel and filigree (openwork); and reliquaries and book covers in gold and silver, set with gems and decorated by embossed figures and scenes, such as the cover of the Codex Aureus of St. Emmeram (*c.* 870; Bayerische Staatsbibliothek, Munich). These pieces testify to the magnificence of Carolingian work, the techniques of which were to dominate the goldsmith's craft until the 11th century.

Ecclesiastical work

Patronage throughout this period was mainly in the hands of the emperors and great princes of the church; and the form of liturgical plate and reliquaries, altar crosses, and the like underwent no fundamental change; Ottonian work of the later 10th and 11th centuries can be distinguished from that of the 9th only in the development of style. For example, the larger, more massive figures, with their strict pattern of folds, on the golden altar (*c.* 1023) given by Henry II to Basel Minster (Musée de Cluny, Paris), are markedly different from the nervous, elongated figures of the Carolingian period.

Romanesque. In the 12th century the church supplanted secular rulers as the chief patron of the arts, and the work was carried out in the larger monasteries. Under the direction of such great churchmen as Henry, bishop of Winchester, and Abbot Suger of Saint-Denis, near Paris, a new emphasis was given to subject matter and symbolism.

Craftsmen were no longer anonymous; work by Roger of Helmarshausen, Reiner of Huy, Godefroid de Claire (de Huy), Nicholas of Verdun, and others can be identified; and the parts they played as leaders of the great centres of metalwork on the Rhine and the Meuse are recognizable. Their greatest achievement was the development of the brilliant champlevé enamelling, a method that replaced the earlier cloisonné technique. Gold and silver continued to be used as rich settings for enamels; as the framework of portable altars, or small devotional diptychs or triptychs; for embossed figure work in reliquary shrines; and for liturgical plate.

The masterpieces of the period are great house-shaped shrines made to contain the relics of saints; for example, the shrine of St. Heribert at Deutz (*c.* 1160) and Nicholas of Verdun's Shrine of the Three Kings at Cologne (*c.* 1200). In the latter, the figures are almost freestanding, and in their fine, rhythmic draperies and naturalistic movement they approach the new Gothic style.

Shrines and reliquaries

Gothic. The growing naturalism of the 13th century is notable in the work of Nicholas' follower Hugo d'Oignies, whose reliquary for the rib of St. Peter at Namur (1228) foreshadows the partly crystal reliquaries in which the freestanding relic is exposed to the view of the faithful; it is decorated with Hugo's particularly fine filigree and enriched by naturalistic cutout leaves and little cast animals and birds.

The increasing wealth of the royal courts, of the aristocracy, and, later, of the merchants led to the establishment of secular workshops in the great cities and the foundation of confraternities, or guilds, of goldsmiths and silversmiths, the first being that of Paris in 1202.

As in architecture, monumental sculpture, and ivory carving, the lead held by Germany and the Low Countries during the Romanesque period now passed to France. Architectural forms continued to be the basis of design in precious metal; the silver shrine of St. Taurin at Évreux (*c.* 1250), for example, is a Gothic chapel in miniature,

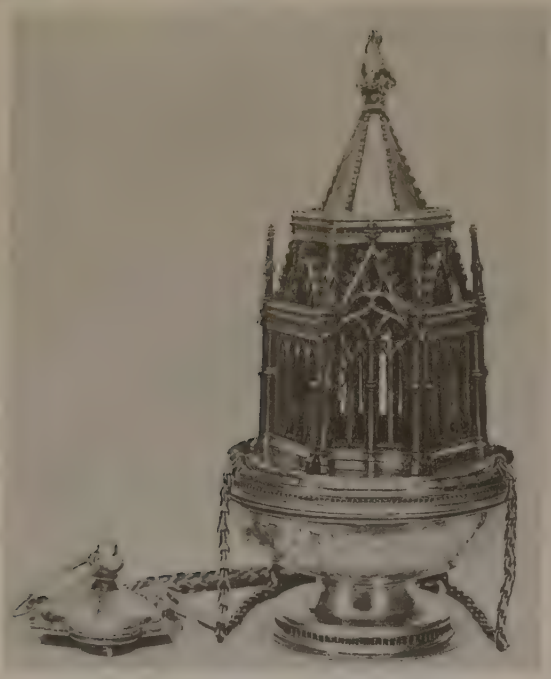

Figure 164: Ramsey Abbey censer, cast, embossed, and gilt silver, English Gothic, 14th century. In the Victoria and Albert Museum, London. Height 27.6 cm.

with saints under pointed arches, clustered columns, and small turrets. In England, the few pieces that survived the dissolution of the monasteries in the 16th century follow the same architectural pattern. Notable examples are the 14th-century Ramsey Abbey censer (Figure 164) and the magnificent crosier made for William of Wykeham (New College, Oxford). Germany first produced work in the Gothic style in the second half of the 14th century with a large Gothic head reliquary of Charlemagne and the splendid "Three-Tower" reliquary, both still at Aachen.

Basse-taille enamel

In Italy, despite the undercurrent of classical taste, the Gothic style predominated in the 14th century, especially at Siena; it was also probably in Italy around 1280 that basse-taille enamel—a technique in which intaglio relief carving in the metal below its surface is filled with translucent enamel—originated, whence it spread rapidly through the upper Rhine region to France and England. The Parisian school of enamellers predominated in the latter half of the 14th century. For the first time, enough secular plate survives to show that it equalled the ecclesiastical in opulence: two fine pieces are the Royal Gold Cup made in Paris around 1380 (British Museum) and the so-called King John's Cup, probably English work of around 1340 (King's Lynn, Norfolk).

The late Gothic period produced court treasures such as the "Goldenes Rössel" (1403; Stiftskirche, Altötting, West Germany), and the Thorn reliquary (British Museum), both early 15th century. There was also an increased output of secular silver because of the rise of the middle classes; the English mazers (wooden drinking bowls with silver mounts) and the silver spoons with a large variety of finials are examples of this more modest plate. Numerous large reliquaries and altar plate of all kinds were still produced. At the end of the Middle Ages the style of these pieces and of secular plate developed more distinctive national characteristics, strongly influenced by architectural style: in England, by the geometric patterns of the Perpendicular; in Germany, by heavy and bizarre themes of almost Baroque exuberance; and in France, by the fragile elegance of the Flamboyant.

"Hallmarking"

The purity standards of silver became rigorously controlled, and "hallmarking" was enforced; the marking of silver in England, especially, was carefully observed.

(P.E.L.)

Islām. The use of gold and silver in Islāmic lands was limited because it was forbidden by the Qur'ān, and although the prohibition was often ignored, the great value of such objects led to their early destruction and melting down. Islāmic jewelry of the early period is therefore of extreme rarity, represented only by a few items, such as buckles and bracelets of the Fātimid and Mongol periods and such pieces as the Gerona silver chest (akin to similar ivory coffers) in Spain and the Berlin silver tankard of the 13th century, with embossed reliefs of Sāsānian animal friezes. (H.Go.)

Renaissance to modern. *16th century.* Italian goldsmiths preceded the rest of Europe in reverting to the style of Roman antiquity; but in the absence of antique goldsmiths' work, vases of marble or bronze had to serve as models. Goldsmiths often worked from very free interpretations of the antique made by artists in other media. Many of these designs but very few of the actual pieces have survived; the most famous is an enamelled gold saltcellar (Kunsthistorisches Museum, Vienna) made for Francis I by the celebrated Florentine Benvenuto Cellini. In the second half of the 16th century many gifted Italian and immigrant goldsmiths worked at the court of Cosimo I, grand duke of Tuscany, specializing in vessels of hardstone mounted in enamelled and jewelled gold; their work is well represented in the Museo degli Argenti in the Pitti Palace, Florence, and in the Kunsthistorisches Museum; similar work was done by the Sarachi family in Milan.

Little French goldwork is extant, and most of the surviving material is in the Galerie d'Apollon in the Louvre. Among the most sumptuous pieces are a sardonyx (a type of onyx) and gold ewer, the gold St. Michael's Cup (both at the Kunsthistorisches Museum), and a sardonyx-covered

Figure 165: *Custodia* of goldwork, silverwork, and enamel work (1515–23), by Enrique de Arfe. In the Toledo Cathedral, Spain. Height 2.50 m.

cup in the Louvre, all of which display northern features. The massive plate of the Ordre du Saint-Esprit (Louvre), dating from 1581–82, is of quite individual character; and an enamelled gold helmet and shield of Charles IX (1560–74) in the Louvre have no parallel either for quality or opulence.

Spanish and Portuguese goldsmiths

In other parts of Europe, goldsmiths clung to Gothic forms until well into the first half of the century, especially in the provincial towns. Immensely rich in ecclesiastical silver, Spain has little early domestic silver; Spanish silversmiths, *platería*, gave their name to the heavily ornamented style of the period, Plateresque. Using precious metal from the New World, goldsmiths such as Enrique and Juan de Arfe produced vast containers for the Host known as *custodia* (Figure 165). The most important Portuguese work, the Belém monstrance, created by Gil Vicente in 1506 for Belém Monastery near Lisbon, is still Gothic in style; later, Portugal developed its own style, related to Spanish work but not copied from it.

Some of the finest 16th-century goldsmiths' work was executed in Antwerp and elsewhere by such Flemish goldsmiths as Hans of Antwerp, goldsmith to Henry VIII, and Jacopo Delfe, called Biliverti, goldsmith to Cosimo I. The Flemish masters showed particular sympathy for the Mannerist style, derived from Italy but transformed by such native engravers as Cornelis Bos and Cornelis Floris. By about 1580, Dutch goldsmiths had begun to rival the Flemish; the van Vianen family of Utrecht won international renown, especially Adam, who excelled at embossing, and his brother Paulus, who worked in Italy, Munich, and in the workshop of Rudolph II at Prague.

The principal centres in the north were Nürnberg and Augsburg, the former particularly notable for the exuberant Mannerism of the Jamnitzer family, the latter for its ebony caskets with silver-gilt mounts. Many German princes, especially the dukes of Bavaria, maintained their own court workshops. Production was on a vast scale, and great quantities survive. Characteristic German forms are columbine cups (the trial piece for entry into the Nürnberg Goldsmith's Guild) and standing cups such as the Diana Cup (Figure 166) by Hans Petzolt.

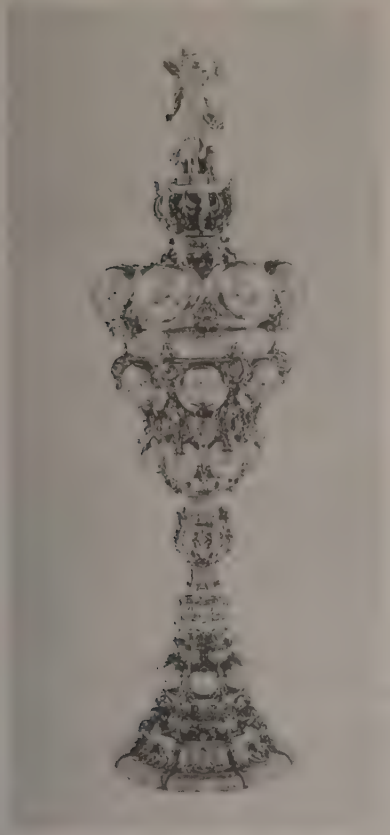

Figure 166: Diana Cup, silver standing cup by Hans Petzolt, Nürnberg, *c.* 1610. In the Kunstgewerbemuseum, West Berlin. Height 80.01 cm.

England is rich in 16th-century secular silver, but church plate was mostly destroyed during the Reformation. The Renaissance style, introduced by the painter Hans Holbein the Younger, who designed vessels for the court, follows that of the Low Countries and Germany. Certain individual forms also were produced, such as standing saltcellars with tiered covers and "steeple" cups, which had a tall finial on the cover.

Baroque. In the first half of the 17th century Dutch goldsmiths, such as the van Vianens and, later, Johannes Lutma the Elder of Amsterdam, developed a fleshy form of ornament known as auricular, which became common in northern Europe, including England—where Christian van Vianen worked as court goldsmith to Charles I—and Germany—where the Thirty Years' War (1618–48) reduced both the quantity and quality of production. After midcentury, bold Dutch floral ornament—usually embossed in thin metal, as though the pieces were for display rather than use—was characteristic and influential. France, however, undoubtedly led fashion with its state workshops at the Gobelins, the refined French acanthus ornament contrasting sharply with the coarser Dutch designs. Since Louis XIV melted the royal plate to pay his troops, no French work of this period remains; but its quality is demonstrated in the work of the Huguenot silversmiths who left France after the revocation of the Edict of Nantes in 1685. Mostly provincials, they brought new standards of taste and craftsmanship wherever they settled—particularly in England, where the foremost names of the late 17th and earlier 18th centuries were of French origin: Pierre Harache, Pierre Platel, David Willaume, Simon Pantin, Paul de Lamerie, Paul Crespin, to mention but a few.

Silver furniture

Silver furniture, a feature of the state rooms at Versailles, became fashionable among kings and noblemen. It was constructed of silver plates attached to a wooden frame; and each suite contained a dressing table, a looking glass, and a pair of candlestands. In France such furniture did not survive the Revolution; but much remains in England, Denmark, Germany, and Russia.

After the Thirty Years' War, Germany did not regain its eminence; even the enamelled goldwork from the court workshops at Prague and Munich, which became larger and more ostentatious in colour, was inferior in design and finish. In Scandinavia, particularly Sweden, goldsmiths evolved forms of beakers and tankards showing strong German influence. Spanish silver was of massive architectural design, oval champlevé enamelled bosses being set at intervals over the surface of the larger pieces. The few extant Italian pieces suggest that the goldsmiths worked their material with the skill of sculptors.

18th century. Early 18th-century English work combined functional simplicity with grace of form, while the work of Dutch and German goldsmiths is in a similar style but of less pleasing proportions. The preeminence of the English work, however, is due to the destruction of all but a fraction of French silver of the same period; for what survives is outstanding in originality of design and fineness of finish. The superiority of French work lay in its excellence of design and the high quality of the cast and chased work. Where other goldsmiths worked in embossed metal, the French modelled and cast their ornament and then applied it—a technique that consumed much more of the precious material.

Superiority of French work

In France, provincial goldsmiths competed successfully with those of the capital; but in England all the best artists went to London. In the early 1730s the French Rococo style was imported to England and adopted by goldsmiths of both Huguenot and English descent, one of the latter being Thomas Heming, goldsmith to George III. English silver in the 18th-century classical style of Robert and James Adam is of unequal merit owing to the use of industrial methods by some large producers.

In France, Robert Auguste created pieces of great refinement in the Neoclassical style, which was copied in Turin and in Rome, for example, by L. Valadier. A notable

workshop was founded in Madrid in 1778 by D. Antonio Martínez, who favoured severely classical designs. In both the northern and southern Netherlands, local production followed French precept, but more individuality survived in Germany. In Augsburg, excellent table silver was produced, but more important were the pictorial panels embossed in the highest relief by members of the Thelot family and the silver furniture made by the Billers and the Drentwetts. At Dresden, Augustus II the Strong established under Johann Melchior Dinglinger a court workshop that produced jewels and enamelled goldwork unequalled since the Renaissance; and the gold snuffboxes made by Johann Christian Neuber rivalled those of the Parisian goldsmiths. (J.F.Ha.)

Colonial America. Silversmithing in the New World in the colonial period is more or less derivative from Europe and England. In North America it was first brought to New England by English craftsmen in the 17th century. The most important centres were Boston, Newport, New York City, Philadelphia, Baltimore, and Annapolis. Outstanding collections include the Mabel Brady Garvan collection at Yale University and those in the Boston Museum of Fine Arts, the American Wing of the Metropolitan Museum of Art, and in the Philadelphia Museum of Art. North American colonial silver is distinguished for its simplicity and graceful forms, copied or adapted from English silver of the period. On the other hand, the colonial silver of Mexico, Brazil, Colombia, Peru, Chile, and Bolivia, while European in concept, shows a blending of Iberian designs and forms, with indigenous influences that trace back to pre-Hispanic times. Most of these relics survive in churches as sacramental vessels; but there are some notable private collections. (D.T.E.)

Colonial silver of Mexico and Central and South America

19th century. The Napoleonic adventure brought French fashions back into prominence, and the Empire style was widely followed on the Continent. In England the Regency goldsmiths, of whom Paul Storr was the foremost, created their own more robust version of the Empire style. Perhaps the most impressive monument of the period is a service made in Lisbon between 1813 and 1816 and presented to the Duke of Wellington for his liberation of Portugal (now in Apsley House, London).

By midcentury most of the earlier styles had been revived fleetingly and a recognizable Victorian style evolved, based on details drawn from diverse sources. Craftsmanship was at its best, but the design of domestic silver was derivative and selective, while that of presentation pieces strove too consciously for naturalistic effect. In the latter half-century the craft became an industry and the goldsmith a factory worker. In this respect Matthew Boulton was the great pioneer: his Soho manufactory near Birmingham, which dominated the British "toy" industry from the 1770s, produced high-quality steel buckles, buttons, coins, sterling silver, and Sheffield plate, establishing standards of design and of factory management and welfare services that rivalled those of the 20th century. At the end of the 19th century, standards deteriorated, and a second pioneering movement started—the craft revival associated with William Morris and the Art Nouveau style (see below *Modern*), which led to the production of original pieces, some of highly mannered design. In England the most interesting work was done by the sculptor Sir Alfred Gilbert, who, following the lead of William Burges, the architect and designer, combined silver with ivory and semiprecious stones in romantic confections. (J.F.Ha.)

The craft as industry

Modern. The structure of trade, following the drastic social changes that have taken place since 1914, is similar in all industrial countries. A few artist-craftsmen maintain independent studio workshops, producing commercially unprofitable but artistically significant work. Many of them also teach in art schools or work part-time in factories as industrial designers. Factories using modern equipment—for example, stamping, pressing, spinning, casting, and mechanical polishing—account for nearly all the financial turnover but seldom break new ground artistically. Retail shops buy stock almost entirely from the factories and wholesalers and usually sell it anonymously. Thus, the evolution of style is impeded by the cost of new machinery; by the natural caution of wholesalers and retailers; by the buying public, which prefers precious ornaments to be timeless; and by the consideration that buying is an investment for value rather than for beauty. In consequence, the most lively designs are often those for costume jewelry; and the best modern work usually has been on a tiny scale, making little impact on the trade.

Decline of creativity

In Paris, designs by René Lalique inspired Art Nouveau, which spread to Belgium and then through Europe and the United States. In Moscow, Peter Carl Fabergé set a superb standard of craftsmanship for small ornaments. In Denmark, Georg Jensen, with Johan Rohde and others, achieved not only an individual Danish style but built up several factories with retail outlets across the world, thus proving that good modern design in silver and jewelry need not be confined to artists' studios (Figure 167); their influence spread throughout Scandinavia. In the 1960s only Germany approached Scandinavia in the number and quality of its artist-craftsmen; WMF (Württembergische Metallwarenfabrik) at Geislingen is probably the biggest silverware factory in Europe. In England, notable for the most varied work, the Worshipful Company of Goldsmiths has helped a vigorous group of designers to emerge since 1945, including Gerald Benney, Eric Clements, David Mellor, John Donald, and Andrew Grima. PEWTER

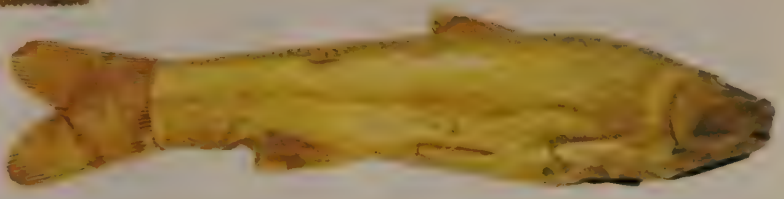
In its pure form, tin is far from suitable for making into implements because it is too brittle for casting successfully and is not easy to melt down. For this reason it has always been alloyed with certain other metals, mainly lead, in the proportion of 10:1, or copper, alloyed about 100:4, to make what is known as pewter. In medieval Germany, the municipal authorities and the guilds laid down permissible ratios to be used for tin alloys. The authorities also kept an eye on the pewterers and their products to make sure that regulations were adhered to. So that pewter ware could be kept under constant surveillance, a system was worked out whereby every single article had to be marked by one, two, or more hallmarks, or "touches." The first decrees of this kind to be issued in Germany date from the 14th century. In France and England, written sources refer to the pewterer's obligation to hallmark his wares from the end of the 15th century onward. These regulations do not seem to have been followed very closely in practice, for pieces surviving from the period before 1550 rarely have the regulation marks. In the second half of the 16th century, however, which was the golden age of pewter, almost all work began to be clearly marked. This means that modern collectors have a good chance of being able to identify their pieces.

Pewter ware is cast in molds. It is not suitable for chas-

Book cover of the Lindau Gospels (MS. 644, fol. 115v), chased gold with pearls and precious stones, Carolingian. In the Pierpont Morgan Library, New York City. 27 × 35 cm.

English silver tureen with the Cavendish arms by Paul Storr, 1820–21. In Chatsworth House, Derbyshire. Height 49 cm.

Silver and gold work



Persian vase in the form of a fish, gold sheet decorated with incised lines, details of eyes and mouth in repoussée, Achaemenid period, 5th–4th century BC. In the British Museum. Length 24.2 cm.

Furniture in the king's bedroom, Knole House, Kent, England, silver on wood, 17th century. Height of table 61 cm.

Mask of Xipe Totec, gold, cast by the "lost-wax" method, Mixtec culture, *c.* 900–1494. In the Museo Regionale, Oaxaca, Mexico. Height 7 cm.

Pewter molds

ing or stamping. Molds for simple utensils such as plates, bowls, and jugs were made of clay mixed with calves' hair or of plaster, stone, or slate. From the 16th century, when pewter ware began to be decorated with relief work, molds made of brass or copper were used instead. Relief decoration can be applied by two different methods. The pewterer could either chisel the relief decoration (consisting of little scenes, figures, or decorative motifs) into the copper mold in intaglio, which enabled him to make the details as three-dimensional as he wished; or he could etch it in, which involved covering the plain copper mold with wax, scratching the decoration into it, and then allowing caustic acid to act on it. This second method resulted in a rather flat, two-dimensional relief, which is reminiscent of woodcuts in its sharp outlines and overall style; thus, the technique is known as the "woodcut style." It was common practice in Nürnberg in the last quarter of the 16th century. Pewter utensils (exclusively plates and dishes at this time) were cast in molds prepared in this manner. It was very seldom that decorative motifs were etched straight onto the pewter surface.

Another type of decoration is engraving, which involves cutting decorative motifs, figures, or inscriptions with a burin into the surface of pewter objects. The most expensive and aesthetically important pieces of engraved pewter were produced in the late Gothic period, about 1500. In the 16th and 17th centuries, engraving was common for guild articles; and in the 18th century engraved mottoes, names, dates, and motifs taken from popular art were widely used. The type of strokes used fall into three categories: long, engraved lines; dots set close together to form a pattern; and a technique known in German as *Flecheln*, in which the straight line made by the burin is broken up into a series of long or short zigzag strokes. The last method makes the design look fuller and broader and also makes it stand out more sharply. This type of decoration first appeared in the 16th century and was very popular in the 17th and 18th centuries.

After they had been cast and then turned on a lathe, many pewter articles, especially plates and dishes, were hammered. The idea was to smooth over the surface of the object and strengthen the material by means of a series of light and regular blows. Sometimes pewterers punched their wares with decorative motifs stamped close together to form a sort of frieze. This technique is known as tooling and is commonly found on bronze and silver articles. Occasionally, pewter pieces were embellished by the addition of brass fittings, such as handles, knobs, spouts, or scroll panels. But pewter ware has rarely been gilded, partly because it is difficult to make a layer of gilding adhere to the surface, partly because there seems little point in covering a material that is attractive in itself with a metal that is ostensibly more precious. This is also why pewter ware has rarely been painted.

Pewter inlay

A type of pewter inlay is found on what are known as Lichtenhain tankards. Most of these tankards were made in Lower Franconia and in Thüringia in the 18th and 19th centuries. They have wooden staves running down them, and their sides are inlaid with decorative motifs and figures made of thin sheets of engraved pewter. In the early 18th century, furniture was also occasionally inlaid with pewter. Such furniture was clearly inspired by the inlay work of the French cabinetmaker André-Charles Boulle.

Antiquity. On the whole, excavations have unearthed little pewter ware dating from antiquity, not only because it has tended to perish over the years but presumably also because it was not nearly as common as glass, bronze, silver, or clay. Excavations on the Esqueline Hill and finds from the Tiber River have produced some small pewter statuettes of divinities that may well be votive offerings. Miniature versions of household articles such as amphorae, oil lamps, and pieces of furniture were found in graves.

A number of pewter ampullae (flasks with a globular body and two handles) with inscriptions or highly stylized images or symbols date from the Early Christian period. They were sold to pilgrims and were used to hold water from the Jordan River, consecrated water, or oil. (Similar pouch-shaped ampullae reappeared in France in the 14th and 15th centuries; but unlike the early Christian examples, they are ornamented with abstract motifs rather than figure decoration.)

Middle Ages. Besides the ampullae, hundreds and thousands of pilgrim badges were sold to devout visitors to places of pilgrimage in the Middle Ages. These little plaques and *agraffes* (hat badges) were generally miniature versions of religious images worshipped at the place where they were on sale. A number of these Italian, English, French, and German pilgrim badges, dating from the 13th to the 16th century, have survived.

Instead of jewelry made of gold, silver, or precious stones, the less wealthy people of the Middle Ages wore pewter badges sewn onto their clothes or hats. The badges often took the form of amulets.

Because pewter was highly prized in all periods, damaged or old-fashioned utensils were melted down over and over again to make new ones. Thus, the earliest surviving functional objects and vessels made of pewter date from the Gothic era, though a few written sources refer to pewter being used earlier than this. Most of these documents are concerned with the question of whether communion chalices should be made of anything other than gold or silver. Pewter Communion chalices were permitted in certain periods and prohibited in others, and the church never managed to draw up an absolute ruling that applied to all religious communities.

Guild flagons

Some of the finest and most important pewter pieces ever cast were made in Silesia in about 1500. Large guild flagons of a characteristic polygonal design, only 11 of them have been preserved. Their facetted surfaces are engraved with figures of saints surrounded by interlaced foliage scrolls, arches, arcades, and other late Gothic decorative motifs. Hidden among these motifs, one sometimes finds secular scenes, some of which are downright lewd. Pewterers in the neighbouring districts of Moravia and Bohemia also made guild flagons; but theirs were cylindrical, with raised horizontal bands. The areas between the bands were generally decorated with friezelike inscriptions made up of Gothic or Gothic-style characters.

The 15th century saw the emergence of a jug set on a slender stem, easily recognizable by its disk-shaped base, surmounted by another slender stem; the main body of the vessel is generally spherical and has a long, thin neck. The municipal authorities often possessed a set of six or 12 flagons of this kind. They came back into fashion in the 17th century and were very widely used, as they had been at the beginning of the 15th century. Unfortunately, only a very few have survived from the earlier periods.

Another early type of vessel belongs to a group known as Hanseatic tankards. These tankards have a heavy-looking, potbellied body set on a shallow circular base and a slightly convex lid. They were used in the coastal regions of Germany—that is, along the North Sea and Baltic coasts—and also in the Low Countries and Scandinavia. These regions comprise the area dominated by the Hanseatic League in the Middle Ages, hence the name of the tankards. Other regions of Europe were evolving their own special types of vessels for beer and wine, which, with a few modifications, remained standard for centuries. Thus, it is a very simple matter to distinguish between baluster jugs from London and *pichets* from Paris or between wine flagons from Switzerland and those made in the Low Countries, Burgundy, the Main regions of Franconia, southern Germany, and the Rhineland. The type of a baluster jug made in the region around Frankfurt-am-Oder and in Brandenburg in northeastern Germany is particularly elegant and distinguished looking. The few jugs of this type that have survived date from about 1500.

In all of the districts bordering the Rhine, vessels with flat lenticular (the shape of a double-convex lens) bodies are relatively common. They were used as canteens—sometimes as tankards, in which case they had a base that acted as a stand.

16th century to modern. The Baroque era saw the production of many different types of drinking and pouring vessels, often made of pewter. The guilds, for instance, commissioned drinking vessels in the shape of larger than life-size versions of the tools of their trade or their coats of arms. Another type of vessel was called the Welcome,

a drinking vessel that was handed around as a form of greeting or when a toast was being drunk. The body of these vessels was generally cylindrical or potbellied, with a lid and a short shaft set on a circular base.

Far fewer plain everyday plates have survived from the 15th and 16th centuries than drinking vessels and containers of the same period. The earliest pewter plates and bowls to have survived in any quantity date from the 17th century.

"Display pewter"

In the last half of the 16th century two places in Europe evolved quite independently, though simultaneously, a new technique for casting pewter. The product was a type of relief-decorated ware known as "display pewter" (*Edelzinn*), and it gave a new and brilliant impetus to the trade. The first examples were made between 1560 and 1570, and the main centres of production were Nürnberg and Lyon. In the beginning the technique used was not the same in both towns. Whereas in France, relief pewter was cast in engraved brass molds worked with a burin, in Nürnberg etched molds were used. This suggests that the two towns were not influenced by each other in any way. Later on, however, Nürnberg pewterers were strongly influenced by the work of a celebrated French pewterer, François Briot, who was active in Montbeliard, in the county of Württemberg.

The first master pewterer documented to have made relief pieces in Lyon is Roland Greffet, between 1528 and 1568. One can assume that it was he who invented this type of work. A school producing tankards and dishes with relief decoration soon grew up in Lyon. The most common decorative motif was an arabesque, which was used in a variety of ways and can be thought of as the leitmotif for the work of this group of artists. The master of relief pewter was François Briot. His most famous piece is the Temperantia Dish (Figure 168), which takes its name from the allegorical figure of Temperance or *Temperantia* that appears in the centre of it. It dates from 1585–90.

Giraudon—Art Resource

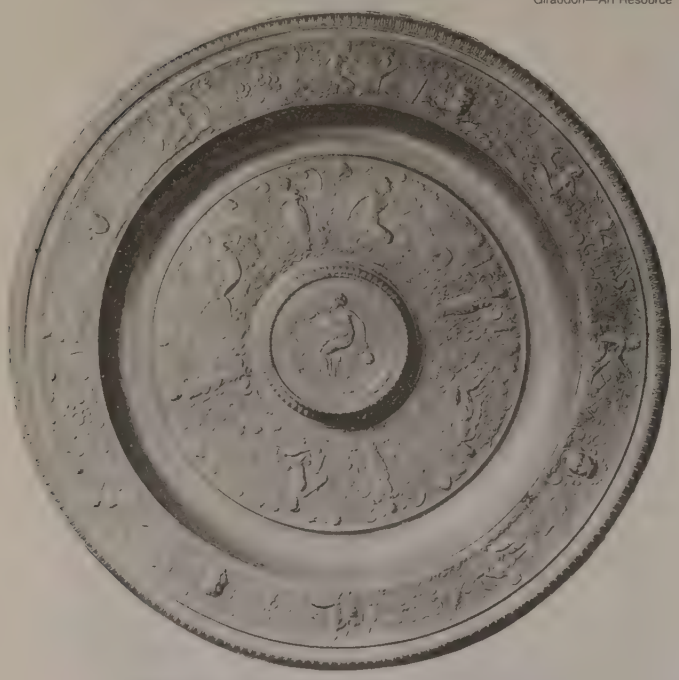

Figure 168: Temperantia Dish, relief-decorated "display pewter," by François Briot, 16th century. In the Louvre, Paris. Diameter 45 cm.

Pewter with etched relief decoration was made by Nürnberg pewterers from the last third of the 16th century onward. The earliest piece made by Nicholas Horchhaimer, bearing the date 1567, is a dish cast in an etched mold with an allegorical figure representing Fame, or *Fama*, in the centre and historical scenes or incidents from classical mythology around the edge. Other large dishes made by Horchhaimer and his contemporary Albrecht Preissensin are again decorated with themes from classical antiquity or sometimes with biblical scenes; for smaller plates they kept to abstract decoration.

The use of etched molds did not remain fashionable in Nürnberg for long, and toward the end of the 16th century engraved molds were being used here as well. The work of François Briot was copied by Caspar Enderlein, who modelled his own Temperantia Dish directly on Briot's. The decoration on the ewer that went with it was modelled on Briot's Mars Dish and on a piece known as the Suzannah Dish, which is also attributed to Briot.

In the second quarter of the 17th century, smaller relief plates superseded the big dishes and jugs made in Nürnberg. The Mannerist allegories that had been in favour completely disappeared, to be replaced by scenes from the Old and New Testaments, equestrian portraits of the German emperors with the electors round the edge, and luxuriant floral decorations. These plates are no more than about seven inches (18 centimetres) in diameter and are generally flat and disk-shaped. The molds were no longer made by the pewterers themselves but by professional mold cutters, who occasionally added their own monograms. Since molds were often sold by one workshop to another and then to another, one sometimes finds plates cast in the same mold but with different touches. Small decorative plates of this type were so popular that they continued to be made as late as the 18th century. There are no less than nine different models for a plate with an equestrian portrait of Ferdinand III of the House of Habsburg, who was crowned emperor of Germany in Nürnberg in 1637. Similar plates depicting Gustavus Adolphus of Sweden, the Emperor of Turkey, and Duke Eberhard im Bart of Württemberg were also produced.

Few places, apart from Nürnberg and France, had a flourishing trade in relief pewter. A few master pewterers in Saxony did execute relief decoration, however, mainly on jugs; they adapted their motifs from lead or bronze plaquettes made in southern Germany. Plates bearing the arms of Switzerland were also produced by Swiss pewterers in the 17th century. They have scenes taken from the history of Switzerland. The golden age of relief pewter, which had begun about 1570, ended in the third quarter of the 17th century. During this period, individual craftsmen had elevated pewter from its humble status as a material from which functional articles were made to one in which brilliant artistic feats could be performed. Relief pewter pieces were solely works of art, nonfunctional objects valued as showpieces.

Pewter dishes made in Italy in the 16th and 17th centuries have chased, etched, engraved, or chiselled decoration and lean heavily on artists working in brass or bronze for their designs. An independent pewter trade does not seem to have existed in Italy on anything like a large scale until the 18th century.

Domestic pewter in northern Europe

After the Thirty Years' War the production of functional articles in pewter noticeably increased in northern Europe. Besides a very large number of different types of jugs, each region specializing in its own characteristic design, there were plates and dishes used at table and also basins and bowls, drinking mugs, and screw-top flasks.

Yet pewter was already feeling the draught of competition by the end of the 17th century. In this time pewter began to be superseded by products of other branches of the decorative arts. Its first rival, faience ware, was initially no more than an inferior substitute for porcelain; but because the factories that were soon springing up everywhere were able to produce very large quantities of faience, they inflicted heavy damage on the pewter trade. Faced with this situation, the pewterers switched to imitating the designs used by the silversmiths, in the hope of gaining favor in the more ambitious middle class circles. This attempt was successful; and, from the first quarter of the 18th century onward, "silver-type pewter" gained a firm hold, soon influencing the production and appearance of pewter ware made in the Regency and Rococo periods.

By about the middle of the 18th century, an ever-widening variety of articles was being made: the pewterers were able to supply anything from a spoon to a whole dinner service, including mustard pots, sauceboats, and spoons for serving punch. But this period of prosperity

was short-lived. By the third quarter of the 18th century, pewter was rivalled both by porcelain, which could now be produced relatively cheaply by several factories in Europe, and by the even cheaper English earthenware that flooded markets on the Continent. This new development sealed the fate of the pewter trade. Towns that once had 20 or 30 busy and successful workshops had no more than one or two by the beginning of the 19th century.

Although in Germany the demand for pewter seems to have increased for a few years after the Napoleonic era, particularly in country districts, by the middle of the 19th century industrialization finally put an end to a trade that had flourished for centuries.

In the second half of the century, when stylistic imitations were all the rage, pewter vessels were produced in the Neo-Baroque, Neo-Rococo, Neo-Gothic, Neo-Renaissance, and other styles that followed the many historicizing trends that emerged. Yet these pieces were made more often by mechanized metalworking factories than by pewterers. The Art Nouveau style that became fashionable at the end of the 19th century brought about a revival of pewter production; and individual firms succeeded in making original, well-designed pieces that are often of considerable aesthetic importance. The firm of Kayser in Oppum near Krefeld played a leading part in this revival (Figure 169).

By courtesy of the Museum fur Kunsthandwerk Frankfurt am Main

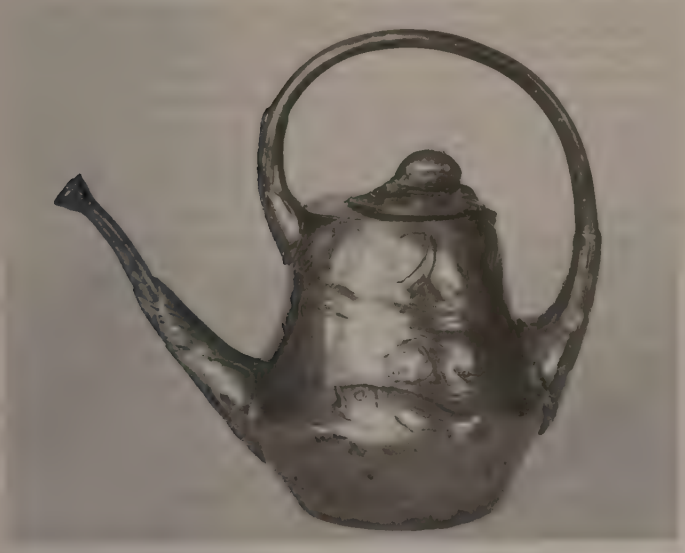

Figure 169: Pewter watering can in Art Nouveau style, by the firm Kayser, at Oppum near Krefeld, Germany, c. 1900. In the Museum für Kunsthandwerk, Frankfurt am Main. Height 21.5 cm.

But the outbreak of World War I spelled the end of Art Nouveau—whose heady run of success had anyway been short-lived—and with it the end of old pewter.

(H.-U.H.)

IRON

Ironwork is fashioned either by forging or casting. Wrought iron is the type of ironwork that is forged on an anvil. There are no fabrication similarities to cast iron, which is poured in a molten state into prepared sand molds.

Wrought iron

Wrought iron is fibrous in structure and light gray in colour. It can be hammered, twisted, or stretched when hot or cold. The more it is hammered, the more brittle and hard it becomes; but it can be brought back to its original state by annealing (heating and then cooling slowly). It will not shatter when dropped.

From earliest times, the smith has had a forge to heat the iron, an adjacent water tank in which to cool it, an anvil on which to form it, in addition to a wide assortment of hammers and tools. The most important tool is the anvil. The English type, generally used for forging wrought iron, has a flat top surface, which is used as a solid base for hammering the heated iron into shape, for welding, for splitting, or for incising decorative chisel marks in the hot iron. One end of the anvil is shaped like a pointed cone and is used for forming curved surfaces. The other blunt end, or heel, has one or two square or rectangular holes on top, into which fit various tools. From the anvil is derived the expression "to strike while the iron is hot," and this implies spontaneity and rapid hammer blows. The wrought-iron craftsman should not be expected to repeat with meticulous exactitude one intricate component after another. In fact, wrought iron by a master craftsman is esteemed for the variations that naturally occur.

Components of wrought-iron design

The individual components of a wrought-iron design are often plain or twisted rods, with or without chisel-mark incisions. They are frequently composed as a series of straight, parallel members or in combination with scrolls, or as a repeat design of some geometric shape such as the quatrefoil. Where two curved members are tangent, they are characteristically secured together by bands or collars, rather than by welding. Where two straight bars intersect, it is accredited craftsmanship to make the vertical bar pierce or thread the horizontal member. Grilles consisting of two series of parallel small-diameter rods, one series at right angles to the other, were sometimes interlaced or woven.

Depending upon the depth of the relief, various fabrication techniques may be employed for repoussé, or three-dimensional, ornamental wrought ironwork. Sheets 1/16 inch (1.6 millimetres) or less in thickness generally are used. The general configuration of the modelling is obtained by beating the back of the sheet; the final details are embossed on the front face. The finer the scale and detail, the more work must be done when the iron is cold. A repoussé design may be pierced; but this term usually connotes a solid sheet forged into a mask, a shield, or an entire embossed panel. The traditional means of setting off a cutout repoussé design was to superimpose it on a vermillion-coloured background panel. Modern approximations of repoussé work consist of mechanically stamped designs touched up with random hammer blows.

(G.K.Ge.)

The most difficult way of decorating iron is to carve it. This involves fashioning figurative or decorative motifs out of the metal ingot with especially strengthened tools, using the material in the same way that the sculptor handles wood or stone. Only very precious iron articles are carved, such as coats of arms or pieces that are specifically designed to be displayed as works of art. (H.-U.H.)

Cast iron

Cast iron is melted in a furnace or cupola, stoked with alternate layers of coking iron, then poured into prepared sand molds. After the cast iron cools in the mold, the sand is cleaned off, and the work is virtually complete. Its shape is fixed, and while a casting can be slightly trued up by the judicious use of a hammer, it is in no sense as workable as wrought iron. Thus, ornamental features in cast iron cannot be chased and polished as in cast bronze. If the ornamental cast-iron details are not replicas of the original pattern, the only recourse is to make a new casting. Because it is brittle, cast iron is almost certain to shatter if dropped.

Since it is cast in a mold, certain forms are more suitable to cast iron than to wrought iron. For example, if repetitive balusters, or columns, or panels with low-relief ornamentation are desired, cast iron is the most suitable material.

(G.K.Ge.)

Early history. The earliest recorded iron artifacts are some beads, dating from about 3500 BC or earlier, found at Jirzah in Egypt. They are made from meteoric iron, as are a number of other objects of only slightly later date that have been found both in Egypt and Mesopotamia. The earliest known examples of the use of smelted iron are fragments of a dagger blade in a bronze hilt, dating from the 28th century BC, found at Tall al-Asmar (modern Eshnunna), in Mesopotamia, and some pieces of iron from Tell Chagar Bazar, in the same area, of approximately the same date. There is, however, no evidence of any extensive use of iron in either Egypt or Mesopotamia before the end of the 2nd millennium BC. In Asia Minor, on the other hand, iron was probably used regularly from at least as early as 2000 BC; and it seems likely that the first true iron industry was established there in the second half of the 2nd millennium BC.

From the ancient Near East the knowledge of iron work-

ing was transmitted to Greece and the Aegean, probably at the beginning of the 1st millennium BC, whence it spread gradually to the rest of Europe. By the 6th century BC, it had been widely disseminated over central and western Europe.

Iron was at first apparently regarded as a precious, semi-magical material, presumably because of its rarity and its connection with meteorites. But once it had become common, as a result of increased knowledge of the technique of smelting ore, it seems to have been used, at least in Europe, almost exclusively for objects of utility. A few Belgic firedogs and at least one amphora, skillfully forged in iron, with decorative terminals in the form of animal heads, are known; but the practice of forging iron into decorative shapes does not seem to have become general until the Middle Ages.

A few cast-iron objects dating from classical times have been found in Europe. The extreme rarity of these, however, suggests that they were only produced experimentally. The earliest known evidence for the general use of cast iron comes from China (see below), and it does not seem to have been produced regularly in Europe before the 15th century. (C.Bl.)

Belgium and Holland. The ironwork of these two small countries prior to the 15th century was in no way inferior to that produced elsewhere. Yet so few pieces remain that the significance of craftsmen of the Low Countries has often been underestimated. During the 15th century, design and craftsmen from the Low Countries began to make their influence evident across the channel in England. Representative examples of this period are in the Hervormde Kerk at Breda; the treasury door of the cathedral at Liège; and hinges of the church of Notre Dame, at Hal. The beautiful spires of Bruges, Ghent, and Antwerp should be mentioned.

Diversified forms of ironwork

During the first half of the 16th century, before the Spanish occupation, there were diversified forms of ironwork, such as protective grilles for doors, windows, and chapels, often in fleur-de-lis patterns; window gratings of vertical bars, frequently octagonal in section; and interlacing bars, producing rectangular or lozenge-shaped patterns. Only a few examples still exist: some lunettes in the Hôtel de Ville of Brussels; a tabernacle grille from the chapel of the counts of Flanders and a window grille from the Cathedral of St. Bavon, both from Ghent (Victoria and Albert Museum); and hinges at the Hôtels de Ville of Bruges and Ypres (Flemish Ieper). Few Renaissance screens have survived.

During the second half of the 16th century, the cruelty of the Duke of Alba and his 20,000 troops, together with the threat of the Inquisition, drove hundreds of artisans to England. After the Spanish domination there was little indigenous design in Holland and Belgium, and such ironwork as was produced fell under the spell of French imports. (G.K.Ge.)

England. The initial use of wrought iron was purely protective because violent attacks were frequent, and doors had to be strengthened with massive ironwork inside and out. Window openings, especially those of the treasuries of mansions and cathedrals, were for similar reasons filled with strong interlacing bars of solid iron; a good example remains at Canterbury cathedral. When, in the course of time, the need for protective barriers ended, there was greater freedom of work and a definite trend toward ornamentation. Throughout England, medieval church doors are found with massive iron hinges, the bands worked in rich ornamental designs of scrollwork, varying from the plain hinge band, with crescent, to the most elaborate filling of the door. Examples exist at Skipwith and Stillingfleet in Yorkshire, many in the eastern counties, others in Gloucester, Somerset, and the west Midlands. The next important application of ironwork came with the erection of the great cathedrals and churches, whose shrines and treasures demanded protection. Winchester Cathedral possesses the remains of one screen with a symmetrical arrangement of scrollwork. Tombs were enclosed within railings of vertical bars with ornamental finials at intervals, such as that of the Black Prince at Canterbury. A new development appeared in the early years of the 15th century when the smith, working in cold iron, attempted to reproduce Gothic stone tracery in metal. This work was more like that of a woodworker than of a smith, often consisting of small pieces of iron chiselled and rivetted, and fixed on a background of sheet iron. Many small objects such as door knockers, handles, and escutcheons were executed in the same manner. A typical monumental example is in Henry V's chantry at Westminster Abbey; but the most magnificent is the great grille at St. George's Chapel, Windsor, made to protect the tomb of Edward IV.

Decoration for church doors

The development of the art of smithing during the Renaissance period was very uneven in the various countries of Europe. In 16th-century England the smith fell behind and seemed to have lost interest, producing no very great or important work. He continued to make iron railings, balconies, and small objects for architectural application, such as hinges, latches, locks, and weathercocks. But toward the end of the 17th century, there was a growing interest in beautifying houses and laying out gardens and squares, with a commensurate demand for balconies, staircases, and garden gates. The man to whom the credit is usually given for the revival of ironwork in England was Jean Tijou, a Frenchman who, together with many of his Protestant fellow craftsmen, had been forced to leave his country owing to the revocation of the Edict of Nantes in 1685. After some years in The Netherlands he went to England in 1689, where he enjoyed the patronage and favour of William III. His most important works for his royal patron are to be seen in the immense mass of screens and gates with which he embellished Hampton Court palace. He also executed work at Burleigh house, Stamford. Probably by the Queen's wish he was associated with the architect Sir Christopher Wren, then engaged on the rebuilding of St. Paul's Cathedral. Wren apparently did not particularly like ironwork and probably exercised some restraint on Tijou, with the result that his work at St. Paul's is more dignified and freer from appendages than that of Hampton Court.

18th-century ironwork

There is a great amount of fine ironwork of the 18th century in London in the form of gates, railings, lamp holders, door brackets, balconies, and staircases; in almost every suburb there are gates and brackets. The precincts of the colleges of Oxford and Cambridge, as well as almost every old town in England, furnish a variety of handsome work. Throughout the 18th century the smith was a busy man; the general tendency of his work, unaffected by the Rococo movement on the Continent, was toward a less ornate but more characteristically English style—perpendicular, severe, lofty, and commanding, as contrasted with Tijou's French love of richness and mass of details.

At the end of the 18th century the work of the architect brothers Adam shows a departure from true smithing; its slender delicate bars are enriched with rosettes, anthemia, and other ornament in brass or lead. The effect is pleasing and harmonizes with the architecture with which it is incorporated.

During the first half of the 19th century, the art of the smith was largely eclipsed by that of the iron caster. But under the stimulus of the Victorian Gothic revival and later of the Art Nouveau movement, there was a renewal of interest in the decorative use of wrought iron, and much excellent work was produced.

Medieval door-hinge ornaments

France. Medieval door-hinge ornaments were not basically different from those in England; and beautiful work is found on church doors, especially in central and northern France. It reaches a height of greater elaboration and magnificence than in England, the culminating example being the west doors of Notre Dame, Paris, the ironwork of which is so wonderful that it was attributed to superhuman workmanship. Grilles at Troyes and Rouen also reveal a high standard of excellence. Working the iron cold and employing methods associated with carpentry was immensely popular; it was applied to small objects such as door handles, knockers, and above all to locks, which exhibit an amazing amount of detail and a remarkable delicacy of finish.

The Gothic tradition survived in France until well into the 16th century and was marked by the production of work of the highest skill, largely in the form of locks,

knockers, and caskets of chiselled iron. The introduction of the Renaissance style did not radically alter the direction of the smith's art—a strange fact when it is remembered that Germany and Spain were fabricating works of enormous size and magnificence in wrought iron. France, like England at that time, was content to make door furniture, in the form of locks, keys, bolts, escutcheons, and the like, but did little ironwork of any great size. A school of locksmiths came into being under Francis I and Henry II, working from designs by Androuet du Cerceau in the 16th century and those by Mathurin Jousse and Antoine Jacquard in the 17th. The bows (a loop forming the handle) and wards (notches) of keys were of unusually intricate design and the locks of corresponding richness. Representative pieces may be seen at the Victoria and Albert Museum. Among them is the famous Strozzi key, said to have been made for the apartments of Henry III, the bow of which takes the favoured form of two grotesque figures back to back. But as far as architectural ironwork was concerned, France remained almost at a standstill until the accession of Louis XIII in 1610. Under that monarch, a worker at the forge himself, came a great revival, which, by the end of the 17th century, had attained a marvellous pitch of perfection. It proved to be the beginning of a new movement, the force of which made itself felt in the adjoining countries and inspired ironworkers with new energy. From the accession of Louis XIV, the French ironworkers must be acknowledged as the cleverest in Europe, combining as they did good and fitting design with masterly execution. Their designs were often very daring, exploiting all the latent and previously unexplored possibilities of iron. They recognized its great adaptability and took every advantage of it, at the same time being conscious of its limitations. Their forms of expression were endless.

Ironwork in the reign of Louis XIV

Screens and gates were needed for parks, gardens, and avenues, staircases for mansions and palaces, screens for churches and cathedrals. Among celebrated designers were Jean Lepautre, Daniel Marot, and Jean Berain. Earlier work had been of a simple character—balconies, for instance, being in the form of a succession of balusters—but as the smith became more versatile and imaginative, they took the form of panels of flowing curved scrolls, rendered with a freedom never attained before, while constructive strength was observed and symmetry maintained. Enrichments were usually attached in hammered sheet iron. These may be considered the distinguishing features of Louis XIV work, such as that at St. Cloud, Chantilly, Fontainebleau, and elsewhere. But under Louis XIV all previous efforts were surpassed in the work for his palace at Versailles.

Rococo design

The art of ironwork received a further impetus by the introduction of the Rococo style. The movement, initiated in 1723, was due principally to the imagination of two artists, Just-Aurèle Meissonier, architect, and Gilles-Marie Oppenordt. There was a balanced asymmetry in the design and fantastic curves with a luxury of applied ornamentation. To the French smith it furnished the opportunity for a yet greater display of his skill. He was clever enough to secure a feeling of stability in his work by counterbalancing swirling masses of ornament with straight constructional lines; he knew how to introduce an iron screen of Rococo style into a Gothic church or cathedral without giving offense to the eye or arousing any uncomfortable feeling of incongruity.

Later in the 18th century, ironwork took on a more classical appearance as a result of the general revival of interest in ancient art; and many Greek and Roman details were introduced into the ornamentation. The amount of work executed was prodigious, and its beauty and craftsmanship may be seen in most cities of France. Nearly all of the adjacent countries, with the exception of England, were seized with the desire to imitate the French Rococo style.

Germany. In the Romanesque period in Germany, bronze was preferred to iron; the earliest examples of ironwork are thus later than those of France and England.

German door hinges

The first iron grilles were imitations of French work, with C-scrolls filling spaces between vertical bars. Typical examples of door hinges prior to the 14th century were those at Kaisheim, St. Magnus Church, Brunswick, and St. Elizabeth's Church, Marburg (the latter having a curious cross in the middle). Throughout the Gothic period in Germany, the imitation of natural foliage was the basis of design.

There were no new marked developments in ironwork during the 14th century. Smiths confined their efforts mostly to hinges. Until this period the vine had been the only motif for elaborate hinges; but flat, lozenge-shaped leaves were introduced, such as those at Schloss Lahneck on the Rhine.

During the 15th century, grilles became more popular. One of the best examples is the grille in the Monument of Bishop Ernst of Bavaria, Magdeburg cathedral (*c.* 1495), with elaborate Gothic tracery, nine columns, and a cornice. In hinges the cinquefoil displaced the quatrefoil, as at Orb, Oppenheim, and Magdeburg. The Erfurt cathedral was enriched with notable hinges having the vine pattern interpolated with rosettes and escutcheons of arms. Hinges for houses usually were the plain strap type, but when ornamented they consisted of superimposed layers of sheet iron. As in other parts of Europe at this time, pierced sheet iron was fashioned into tracery of a semi-architectural nature, much like Gothic windows. Pierced ornament and twisted rods were often combined to form grilles, with their extremities beaten into complicated foliage forms.

During the Renaissance, ironwork in Germany was in use everywhere and for every purpose: for screens in churches, window grilles, stove guards, gates, fountain railings, well heads, grave crosses, door knockers, handles, locks, iron signs, and small objects for domestic use. Smiths were their own designers and more often than not planned intricate devices merely to show their skill in executing them. They set no limits to their problems; and so far as manipulative excellence went, the German smiths were the foremost in Europe. But clever as their workmanship undoubtedly was, their designs frequently showed a lack of stability and a tendency to run riot. Thus, many of their most imposing works consist largely of filling panels with elaborate, interlacing scrollwork, and the sense of constructional and protective strength is missing.

An abundance of smiths' work is to be found in the

Bildarchiv Foto Marburg

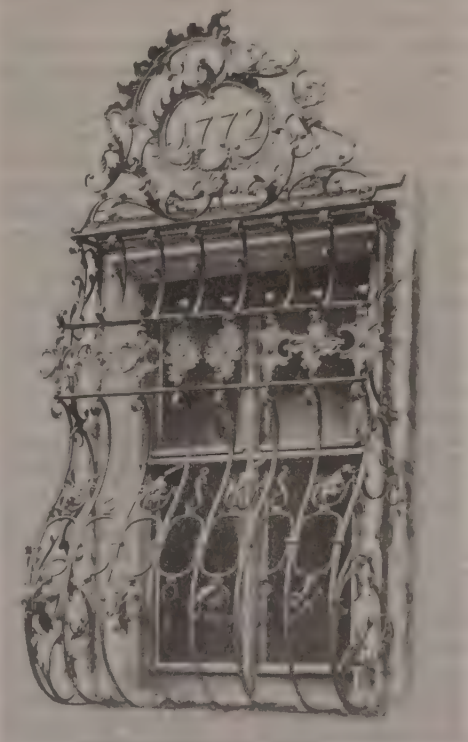

Figure 170: Rococo style wrought-iron window grille from a house on Winklerstrasse, Nürnberg, 1772.

Southern German work

southern parts of Germany. Iron bars, circular in section, were most frequently used; and the most common features are interlacing bars and terminations of flowers with petals and twisted centres, foliage, or human heads. All of these characteristics occur with almost monotonous repetition, witnessing to skill but also to lack of imagination and sense of design. The style may be studied in many German and Austrian cities, such as Augsburg, Nürnberg, Frankfurt, Salzburg, Munich, and Innsbruck (Figure 170).

The German smith gave much attention to door knockers and handles, enclosing them in pierced and embossed escutcheons, and devised locks with very involved mechanism. German influence made itself strongly felt in Switzerland, Austria, and Czechoslovakia.

The Baroque and Rococo periods are distinguished by a perfection of detail that exceeded that of German Medieval or Renaissance ironwork. Smiths used wrought iron as though it were a plastic material, meant to be employed in extravagant forms wherever possible. Some examples are at Zwiefalten, Weingarten, and Klosterneuburg. In the late 18th and early 19th centuries, cast ironwork of outstanding quality was produced in Germany, notably at the Prussian royal foundry established in 1804.

Italy. The few extant examples of ironwork in Italy prior to the 14th century indicate a wide appreciation of how the material could best be worked with only the tools of the smith. Some noteworthy examples are the chancel grille at the left of the nave, Orvieto Cathedral (1337); the grille around the Scaligeri tombs of Verona (*c.* 1340); the grille at the baptistery of Prato cathedral (1348); the chancel screen in the sacristy chapel of Sta. Croce, Florence (1371); and the grille to the Capella degli Spagnoli, Sta. Maria Novello, Florence.

Italian ironwork before the 16th century

Until the 16th century, Italian smiths respected the natural characteristics of wrought iron by relying almost entirely upon those forms that could be wrought with hammer and anvil. The grille was usually made by dividing it into regular panels with vertical and horizontal bars (sometimes triangular in section and enriched with dentils, or small, projecting triangular blocks). Often the quatrefoil filled some or all of these panels; they were made in Tuscany from a pierced plate and in Venice from separate scrolls collared together. A noted example is in the Palazzo della Signoria, Siena, crowned by a repoussé frieze and surmounted by a cresting of flowers, spikes, and some animal heads.

It might have been thought that in the fountainhead of the Renaissance, ironwork would have proceeded at the same pace and with the same brilliant success as architecture, sculpture, bronze casting, and the other arts. Strangely enough, little use of it is found in connection with the fine buildings of the revival. Bronze was favoured; and what in other countries is found in iron has its counterpart in Italy in bronze. As time went on the smiths grew less inclined toward the more difficult processes of hammering and welding and contented themselves ultimately with thin ribbon iron, the various parts of which were fastened together by collars. Work of the later periods may be distinguished, apart from the design, by this feature, whereas the English and French smiths vigorously faced the hardest methods of work, and the German and Spanish smiths invented difficulties for the sheer pleasure of overcoming them.

Notable centres of artistic ironwork were Florence, Siena, Vicenza, Venice, Lucca, and Rome, where important pieces may be found in the form of gates, balconies, screens, fanlights (semicircular windows with radiating sash bars like the ribs of a fan), well covers, and a mass of objects for domestic use, such as bowl stands, brackets, and candlesticks.

Screenwork

In screenwork the favourite motif was the quatrefoil, which has been found with many variations ever since the 14th century. Early examples are strong and virile, but later ones tend to weakness. The C-shaped scroll is also used in many combinations. The churches and palaces of Venice contain many examples of these popular designs. Peculiar to Italy are the lanterns and banner holders such as may still be seen at Florence, Siena, and elsewhere, and the rare gondola prows of Venice. Of the ironworkers of the early Renaissance, the most famous was the late-15th-century craftsman Niccolo Grosso of Florence, nicknamed "Il Caparra" because he gave no credit but insisted on money on account. From his hand is the well-known lantern on the Palazzo Strozzi in Florence, repeated with variations elsewhere in the same city. Siena has lanterns and banner holders attached to the facades of its palaces, and lanterns are still to be seen at Lucca and a few other towns.

The decadence of 17th- and 18th-century ironwork paralleled that of architecture. Designs were borrowed directly from France and Germany. The metal was too often worked cold, using thin members; and the resulting construction was flimsy. Scrolls were often encased in thin, grasslike leaves. Conventional or naturalistic flowers were tacked on as seeming afterthoughts. Instead of using rods and bars, ribbonlike bands were used, with cast ornaments pinned on. Intersecting tracery was copied from Germany. The best examples of this period are confined to Venice and northern Italy, such as the screen in the south aisle chapel of S. Ambrogio, Milan; the chapel enclosure in S. Pietro, Mantua; and the screen in the Palazzo Capodilista, Padua.

Spain. Prior to the 15th century, Spanish ironwork was basically similar to that in France and England. The Spanish smith accepted the limitations imposed by anvil and ancillary tools; but he skillfully exploited to the limit all manner of variations—twisting square rods, coiling flat bars into C-shaped scrolls of all sizes, and devising imaginative crestings to surmount the top of church chapel screens or domestic window grilles. Many Moorish craftsmen of extraordinary ability were enticed to remain in Spain as the Moors were slowly pushed southward; the resultant blending of Gothic with Moorish resulted in the Mudejar style.

Ironwork of the Renaissance period from about 1450 to 1525 reached a height of grandeur and magnificence attained in no other country. Of all the Spanish craftsmen the smiths were the busiest, especially during the 16th century. The ironwork products that for more than a century dominated the craft are the monumental screens (*rejas*) found in all the great cathedrals of Spain. These immense structures, rising 25 to 30 feet (7.5 to nine metres) show several horizontal bands, or tiers, of balusters, sometimes divided vertically by columns of hammered work and horizontally by friezes of hammered arabesque ornament. Usually such screens are surmounted by a cresting, which is sometimes of simple ornament but more often a very elaborate design into which are introduced a large number of human figures. Shields of arms are freely incorporated; and the use of bright colour, silvering, and gilding adds to their impressive beauty. The great balusters were always forged from the solid, and their presence in hundreds demonstrates the extraordinary skill and power of the Spanish smith. In many cathedrals two of these monumental *rejas* are found facing one another. There is at least one in every large cathedral—Barcelona, Saragossa, Toledo, Seville, Burgos, Granada, Córdoba, and many others.

Monumental *rejas*

Ironwork on a smaller scale is found in gates, balconies, and window screens; wrought-iron pulpits also exist. Panels of hammered and pierced iron, heightened with colours and gilding, were used in connection with domestic architecture; and many doors were ornamented with elaborate nailheads or embossed studs.

(W.W.W./G.K.Ge.)

United States. The characteristics of the earliest ironwork in the various colonies naturally reflected those of the parent countries. The English were more sparing in its use in the New England Colonies than were the Germans in Pennsylvania or the French in Louisiana. In the 17th and 18th centuries ironwork was used mostly for such practical purposes as weather vanes, foot scrapers, strap hinges, latches, locks, and particularly for the necessities and conveniences for fireplaces (firedogs, cranes, skewers, toasters, kettle warmers, and spits). It was not until the late 18th century, when the threat of Indian raids and food shortages had waned and the established communities enjoyed a sense of tranquillity and prosperity, that smiths fashioned wrought iron into railings, fences, grilles,

Utilitarian ironwork

gates, and balconies. Square or flat iron bars were generally used to produce designs that were usually light, airy, and graceful and rather in contrast to the contemporary European preference for sturdier forms.

Gradually, ironwork designs tended to develop characteristics of an American or composite nature, as a logical consequence of the diverse origins of colonists and smiths. An innovation that appeared toward the end of the 18th century was the combination of structural wrought-iron rods or bars with lead or cast-iron ornamental features. While the use of wrought iron declined in the 19th century, during its last quarter the use of cast-iron columns and panels for nonresidential buildings increased. These designs, timid or bold, decorative or structural, engendered the prototypes of commercial buildings for the ensuing decades.

Because the life of structures in U.S. cities has been short, there are few examples of 18th- or early 19th-century ironwork extant in New York City, not many more in Boston, some in Philadelphia, but more in and near Washington, D.C., such as the excellent balconies and railings at the Octagon (headquarters of the American Institute of Architects). Charleston, South Carolina, has a rich legacy in gates, notably those at numbers 12, 23, and 36 Legare Street, 63 Meeting Street, and an unusually beautiful pair at St. Michael's Church.

New Orleans ironwork

New Orleans has more ironwork than other U.S. cities, thanks to a group of citizens dedicated to the preservation of the old French Quarter. Its earliest ironwork was forged by Spanish and French smiths. Unfortunately, fires, rust, and remodelling have so taken their toll of the Spanish ironwork that almost the only remaining example of importance is the gateway of the Cabildo (town hall). It has moldings beaten from solid bars, like many of the old *rejas* in Spanish cathedrals. After the Louisiana Purchase in 1803, the influx of ironworkers from northern states brought about a broadening of influences that is apparent in designs and techniques. Ironwork of New Orleans can be roughly divided into three periods: (1) forged wrought iron by French and Spanish artisans with strongly marked European characteristics; (2) a transitional period with wrought-iron structural members embellished with cast-iron ornaments in the Directoire and Empire styles of France, plus some U.S. innovations; and (3) entire grilles, screens, and trellises made entirely of cast iron. No other city in the U.S. has two- and even three-story iron porches and balconies that can compare with those of New Orleans. Some of these lacy structures, such as those on St. Peter Street (Figure 171), were built above the sidewalks. Balconies sometimes not only extended across an entire facade but continued around a corner.

Mid-19th century onward. Distinctive national characteristics in the design of ironwork gradually tended to disappear in Europe because of increased travel and communications between countries. The influence of French Renaissance architecture (modified or revived) continued to exert a viable effect where the acceptance of the Art Nouveau (last quarter of the 19th century) was flaccid or denied. In England, however, 18th-century designs continued with slight modifications. In the U.S. probably the most important force, prior to World War I, was exercised by architects trained in Paris, with the result that ironwork designs were similar to French work of this period.

Effects of increased mechanization

The increased mechanization of all forms of manufacture understandably affected the character and use of ironwork. As the cost of cast iron came down, its use increased. Because wrought iron is produced by hand by beating red-hot iron on an anvil, not much change was possible through increased mechanization, whereas the casting of molten iron lent itself to improved equipment and techniques. The lowered cost of duplicating ornamental cast-iron components and the introduction of structural steel parts expanded the usage of ironwork to the modest building, whereas it had been generally confined to public or monumental structures. Foundries in the U.S. established a flourishing business in pierced cast-iron panels, modelled after Louisiana porch trellises.

Compared with prior periods, the last half of the 19th century will scarcely be commemorated as introducing enduring or beautiful ironwork forms. It was not until the first quarter of the 20th century that a master craftsman-designer gave impetus to a new conception of design forms and textures. Edgar Brandt of Paris broadened the scope of decorative usage by the rich inventiveness of his compositions and by an entirely original approach that resulted in a wrought-iron texture that is akin to beaten silver. Examples of his work at the Exposition des Arts Décoratifs Modernes at Paris in 1925 had an immediate effect upon ironwork designed and executed in the U.S. during the great building boom that lasted until about 1930. During this period, both wrought and cast iron enjoyed an unprecedented period of popularity not only in the form of bank screens, entrance doors, and grilles in public buildings but as decorative grilles and gates in private homes. In many cases the craftsmanship equalled that of representative examples of the Gothic or Renaissance periods in Europe.

One of the most gifted and dedicated iron craftsmen in the U.S., Samuel Yellin of Philadelphia, raised the standards of wrought-iron craftsmanship to its apex during the 1920s. He not only trained an atelier of craftsmen for the first time in the U.S., but by his efforts wrought iron was recognized as capable of enriching even the most monumental building. Yellin's influence, however, was ended by the Depression of the early 1930s. As building activity declined after 1930, so did the use of ironwork; and it did not increase with the revival of building after World War II. (G.K.Ge.)

LEAD

Lead has two main uses in which some artistic purpose may be served: in architecture, as a material for roof coverings, gutters, piping, and cisterns; and in decorative art, as a material for sculpture and applied ornament. As an architectural material it has the advantage of being easily worked and yet offers great resistance to climatic conditions. The low melting point of lead and its relative freedom from contraction when solidifying make it particularly suitable for casting, and it has been used as a substitute for bronze or precious metals.

Antiquity. The earliest known lead sculptures are small

Earliest known lead sculptures

votive figures found at Troy and Mycenae. In the Hellenistic period lead sarcophagi were known, and the Romans made much use of the metal. Large amounts of worked lead in various forms have been found in those parts of England where the Romans had permanent settlements.

Middle Ages. England was one of the main lead-producing areas in the Middle Ages, and lead was more widely employed there than on the continent of Europe. In the 12th century the German monk Theophilus, in his treatise on metalworking, refers to lead only in connection with casting rods for stained-glass windows and as a material through which silver sheets might be hammered; but in England at about the same time a remarkable series of lead fonts was cast, of which 16 still survive in position, the most famous being those at Walton-on-the-Hill, Surrey, and at Wareham and Dorchester in Dorset. Lead was also used in the Middle Ages for church roofing; and it was used, doubtless because of its cheapness, for the small badges or medallions sold to pilgrims at the great medieval shrines. Lead could even be useful, in the proper disguise, to simulate rich ecclesiastical objects, for not all religious institutions were wealthy: a group of 14th-century caskets covered with lead tracery, gilded to look like precious metal, have survived in church treasuries. These were used as reliquaries, but some were originally made for secular purposes.

Renaissance to modern. The Renaissance passion for collecting bronze medals and plaquettes led to a demand for cheap replicas, and these were made with great precision in lead. The metal also played an important role in the goldsmiths' trade. The fashion for elaborate relief ornament of the Renaissance and Mannerist periods called for a degree of skill in modelling that was beyond the powers of the average goldsmith. The practice therefore grew up for the pattern makers of Augsburg and Nürnberg, Germany, to sell lead models of ornamental details and figures from which goldsmiths working elsewhere could in turn make molds. An extensive collection of these models is preserved in the Historisches Museum, Basel, Switzerland. The trade expanded to include large medallions and plaquettes, the chief masters of which were the German goldsmiths Peter Flötner, Jonas Silber, and the Master H.G. (Hans Jamnitzer) and the Dutch goldsmith family of van Vianen. Lead in sculpture is more suitable for the production of small figures than life-size statues, which, if unsupported, become distorted through their own weight. Among the few life-size equestrian lead statues is one of Frederick Louis, prince of Wales, in the grounds of Hartwell House, Buckinghamshire, England. From the 16th century, lead appeared in England in the form of gutters and pipe heads (which carried rainwater down from the gutters), often with cast ornament. Some of the late-17th- and early-18th-century pipe heads, cast with the arms of the owner of the house and the date of erection, are important decorative features.

Lead models

An extension of the use of lead took place with the introduction of lead garden sculpture—figures, vases, and urns—in the late 17th century. An example of this work is a pair of garden vases 15 feet high at Schloss Scheissheim in Bavaria. The silvery gray colour of such sculpture and its resistance to the weather made it suitable for use in the many formal gardens that were created at this time. English garden sculpture rarely achieves any particular aesthetic status; but in 18th-century Germany and Austria lead was used for more serious sculpture by a group of artists of high standing. In the 19th century, lead was out of favour with sculptors, partly because improved transport made it possible to bring marble from Italy at low cost. Its soft colouring and the fact that it does not reflect light give it advantages, however, and it has been used in the 20th century by Aristide Maillol and by Sir Jacob Epstein, who executed the lead figure of the Virgin and Child in Cavendish Square, London. (J.F.Ha.)

Non-Western metalwork

SOUTH ASIA

Iron. The manufacture of iron by primitive smallscale methods has survived in southern India and Ceylon to the present day. The slag heaps of ancient furnaces are common, and the processes have probably been in use for more than 2,000 years; but it is unknown whether they are of indigenous invention or acquired. In southern India iron immediately succeeded stone as a material for tools and weapons, and prehistoric iron weapons began to come into use about 500 BC. The wrought-iron pillar of Delhi, set up about AD 400 by Kumāra Gupta I in honour of his father, is over 23 feet (seven metres) in height and weighs more than six tons. It demonstrates the abilities of Indian metalworkers in handling large masses of material, for not until the latter part of the 19th century could anything of the same kind have been made in Europe. There are other large iron pillars at Dhār and at Mt. Abu. (Ed.)

Gold and silver. In India, gold jewelry has been found from the Indus culture. Excavations at Takshasila (Taxila) have revealed gold and silver drinking vessels and jewelry of Hellenistic types dating back to about the 1st century AD. From the same time is the important Buddhist gold reliquary from Bimaran, Afghanistan, set in rubies and decorated with embossed figures in Gandhāra style (British Museum).

During the Gupta period (AD 320–647), vessels of Hellenistic and Persian shapes were evidently made, for they are represented in the sculpture and frescoes of the period. More Indian in style are a silver dish of the 3rd or 4th century, decorated with a Bacchanalian scene of a *yakṣa* drinking (Figure 172), and a silver bowl of the 7th century

Figure 172: Indian style embossed and chased silver dish showing a *yakṣa* drinking, Kushan, found at Buddaghara, near Tank, Dera Ismāīl Khān district, Pakistan, 3rd or 4th century AD, Gupta period. In the British Museum. Diameter 25.15 cm.

from northern India, which is embellished with medallions in low relief (both in the British Museum). Jewelry played a very important role, and, although no original pieces have survived, it can be studied in frescoes at Ajanta and on contemporary sculptures.

17th-century vessels

In spite of the fact that gold and silver vessels have been common in India since classical times, there is very little material extant before the 17th century, when all kinds of vessels were produced in bronze, brass, copper, and, for the royal houses, in silver. Shapes and decorations vary in different regions. Delhi was famous for its craftsmen, especially in the time of Akbar in the 16th century and Jahāngīr and Shāh Jahān in the 17th. Much work was done in precious metal, and vessels and ornaments of jade were inlaid with gold and gems. Northern India is famous for its enamels. Enamellers from Lahore were brought to Jaīpur in the 16th century by Mān Singh, and enamel was employed extensively in combination with goldwork and silverwork in the 17th and 18th centuries there and elsewhere. The Punjab, Lucknow, and the districts of Chānda and Cutch in Gujarāt state were long celebrated for their metalworkers. In the south, silverwork in *svamin*-style is characterized by religious-figure scenes in relief, executed in three different techniques. Craftsmen

in Tirupati put silver sheet on copper; Madras, Bangalore, and Tiruchirāppalli are known for hammered vessels with traced decoration; and Thanjāvūr (Tanjore) produced a more Baroque effect with inlays of silver in copper. From the former Travancore state, Mysore, and Bijaipur in the southwest come chased vessels with floral patterns, the lotus predominating. In the north the Hindu style is well represented by works from Vārānasi (Benares).

Persian-Islāmic influence

Persian-Islāmic influence is found in several vessel shapes; for example, ewers and basins for water and smoking furniture, such as hookas, which also have Islāmic patterns. Jewelry from the later periods employs precious stones, pearls, gold, and silver in great variety. The old types are repeated, with symmetrical arrangements of rosettes and leaves for bracelets, necklaces, pendants, rings, and foot ornaments. Very fine work in silver filigree was executed at Cuttack in Orissa and was used on jewelry and various larger items.

CENTRAL AND SOUTHEAST ASIA

Indian styles and techniques spread to the neighbouring countries. In Nepal precious metals were used in architecture; pagodas, temples, and palaces sometimes had facades richly decorated with ornaments embossed in gilt copper with settings of precious stones.

In Tibet copper and brass were usually used for vessels, but these metals were often decorated with applied silver or gold ornaments; and in eastern Tibet, especially, teapots were made of silver with gilt appliqué. While many of the ornaments are Chinese, Buddhist shapes and patterns of Indian origin were used for ritual vessels. Other ritual objects were sometimes made of silver or, more rarely, of gold, though bronze is again the common material. Silver is used for amulets and jewelry with rich settings of turquoises, carnelian, and lapis lazuli.

In Thailand, Buddhist vessels were made out of chased silver, very often in the shape of a lotus flower whose petals are decorated with other, embossed, floral and figure motifs.

Burmese gold and silver vessels

Burma is known for its chased silver vessels heavily decorated with figures and floral patterns in relief, related to the south Indian *svamin* work. The use of gold and silver vessels for domestic purposes was denied to all but those of royal blood. Good examples of earlier golden regalia are in the Victoria and Albert Museum.

In Vietnam, goldwork and silverwork of the Cham culture are preserved from the 10th century. It is exemplified by a crown and heavy jewelry made for a life-size statue found in the ruin of a temple at Mison. From later times there is a royal treasure with four crowns, various amulets, arm rings, and table services of gold, richly decorated with embossing and openwork. (B.V.Gy.)

EAST ASIA

China. *Bronze.* Bronzes have been cast in China for about 3,700 years. Most bronzes of about 1500–300 BC, roughly the Bronze Age in China, may be described as ritual vessels intended for the worship of ancestors, who are often named in inscriptions on the bronzes. Many were specially cast to commemorate important events in the lives of their possessors. The vessels were also meant to serve as heirlooms, and the inscriptions often end with the admonishment "Let sons and grandsons for a myriad years cherish and use." These ritual vessels of ancient China include some of the loveliest objects ever made by man, and as a group they represent possibly the most remarkable achievement in the whole history of metalcraft before modern times. Since the vessels can be considered sculpture, they are discussed in EAST ASIAN ARTS.

Among other ritual bronzes, bells constitute an important group. Perhaps the oldest class is a small clappered bell called *ling*, but the best known is certainly the suspended, clapperless bell, *chung*. *Chung* were cast in sets of eight or more, to form a musical scale, and were probably played in the company of string and wind instruments. The section is a flattened ellipse, and on each side of the body appear 18 blunt spikes, or bosses, arranged in three double rows of three. These often show marks of filing, and it has been suggested that they were devices whereby the bell could be tuned to the requisite pitch by removing small quantities of the metal. The oldest specimen recovered in a closed excavation is one from P'u-tu Ts'un, dating from the 9th century BC.

Secular bronzes

Vast numbers of secular bronzes were cast. These include weapons, such as the *chih* and *ko* dagger axes and the short sword; chariot and harness fittings; trigger mechanisms for bows; weights, scales, and measures; belt hooks; and mirrors. The last appear in great numbers from the

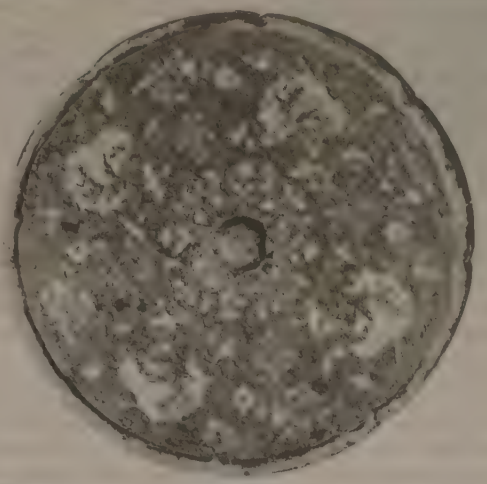

Figure 173: Chinese mirror back, bronze with lacquer, T'ang dynasty (AD 618–907). In the Museum of Fine Arts, Boston. Diameter 21 cm.

5th century BC onward. They are flat disks, with a central perforated boss by which they could be mounted on a stand. Their backs are covered with a maze of intricate relief designs and feature a diversified series of well-defined subjects (Figure 173). (W.Y.W.)

Iron. Iron began to take its place in the brilliant Bronze Age culture of China during the Ch'in dynasty (221–206 BC) and the Han dynasty (206 BC–AD 220). By the end of the 2nd century AD, bronze weapons had been almost completely supplanted, and iron had been generally substituted for bronze in common use in utensils and vessels of various kinds, tools, chariot fittings, and even small pieces of sculpture. These were commonly cast in sand molds, were patterned after bronze prototypes, and were typical of the Han period in style and decoration.

From the 9th century, iron increasingly took the place of bronze in China as a material for sculpture, especially in the north and under the Sung dynasty. The few extant examples from the 11th century and later show work done on a larger scale and in coarser technique than the bronzes, though the modelling is usually more naturalistic.

Several iron pagodas, dating from the 10th to the 14th century and ranging in size from miniature models to towers 100 feet or more in height, give further evidence of the dexterity of the Chinese iron caster. The pagodas imitate, in detail, both the structural and decorative effects of the more common tile-roofed brick pagodas. Iron for temple furniture has long been in use, and a large number of the braziers, censers, caldrons, and bells found today in the temples are of iron.

Iron pictures

In China in the 17th century the iron picture was developed, the craftsmen seeking to reproduce in permanent form through the medium of wrought iron the effects of the popular ink sketches of the master painters. When completed, these pictorial compositions were mounted in windows, in lanterns, or in frames as pictures. When in the latter form, a paper or silk background often bore the signature and seal of the maker, heightening the resemblance to a painting. The craft flourished in Anhwei Province and is still practiced, though with less patience and fineness than formerly. (B.Ma.)

Gold and silver. In ancient China gold and silver were rare. Gold was used as an inlay for bronzes in the Chou dynasty (1111–255 BC), and between the 6th and the 2nd centuries, gilding and silvering were common. Dress

hooks and small items of jewelry were sometimes cast in gold and silver and imitated the more usual bronze forms. Granular work—a technique that probably has an Indian origin—was used for jewelry.

Silverwork first became important during the T'ang dynasty (AD 618–907), when the Chinese had learned from the Sāsānid Persians how to chase the silver. In the beginning, they followed their teachers very closely in the forms of the bowls and larger vessels as well as in the patterns. T'ang drinking vessels, ewers, trays, and lobed oval dishes on a stem are Persian shapes transformed by Chinese taste. Among the patterns are vine and palmette scrolls of great variety, hunting scenes, and landscapes of symmetrical flowers and trees with birds and animals; all of these have parallels in Persian silver and textiles but are more delicate in their Chinese version. The techniques used by the Sāsānid silversmiths were adopted by the Chinese; for example, double sheets for a bowl and tracing of the patterns on ring-matted ground. T'ang jewelry is made of gold or gilt silver.

During the Sung dynasty (960–1279), silverwork declined in technical quality but jewelry played a more dominant role. Hair ornaments became increasingly intricate, with elaborate naturalistic flowers and various auspicious symbols.

Revival of silverwork in the Yüan and Ming periods

During the Yüan (1206–1368) and Ming (1368–1644) periods, skill in silverwork revived, and once again the smiths followed many Near Eastern styles. Drinking vessels (ewers and cups), boxes, and even large ceremonial gold vessels have been found in Ming tombs. During the excavation of the tomb of Emperor Wan-li (1572–1620), a series of gold vessels set with precious stones was found. All of the gold items are decorated with incised patterns of dragons, phoenixes, and similar subjects.

During the Ch'ing period (1644–1911/12), both silver and gold were used lavishly, and gold filigree work especially is common in the 18th century. Most of the forms and ornaments employed, however, are borrowed from lacquer and porcelain ware; and only jewelry has its own style, rich combinations of kingfisher feathers glued to the metal.

Korea. The Chinese colonists who settled Korea during the Han empire (206 BC–AD 220) first brought goldsmiths and silversmiths to Korea. By the 5th to 6th century AD Korean work, as exemplified by large gold crowns and various pieces of jewelry excavated from tombs at Kyŏngju, was beginning to develop distinctive characteristics. At the time of the Unified Silla (668–635) and Koryŏ (935–1392) kingdoms, Chinese influence was strong, but the Korean style persisted in silverwork and goldwork. Several vessels with floral patterns in relief are preserved from these periods. (B.V.Gy.)

Japan. *Iron.* The Iron Age in Japan is supposed to have begun in the 2nd century BC, though the chief early remains are weapons that date from the dolmens of the 2nd to the 8th century AD. The Japanese iron founder attained a considerable skill at an early date and acquired a social position that was never attained by the bronze caster or by the ironworkers in China, where the Bronze Age tradition was much stronger. It is apparent that iron was used in China chiefly as a substitute or imitative medium; it was worked often with great skill but with little artistic invention. In Japan, however, the ironworker developed a distinctive and original means of expression and high artistic attainment in accessories for the sword. With the rise of feudalism and the establishment of the samurai class after the wars of the 12th century, the necessary equipment of the warriors became a focus for the efforts of the artist.

At first these efforts were devoted to the embellishment of defensive armour, but from the 15th century the sword became the centre of attention. The blade is not properly part of the subject of this article; but in the mountings, especially the guards (*tsuba*), is found exquisite artistry expressed chiefly in iron. A remarkably soft and pure variety of the metal especially free from sulfur was employed. It was worked by casting, hammering, and chiselling; and innumerable surface effects were obtained by tooling, inlaying, incrustation, combination with other metals, and patination by various, usually secret, processes. Simple conventional patterns, crests, and pictorial designs were the bases for the decoration. As these were often furnished by painters or designers, the criterion of connoisseurship in Japan is the unsurpassed technical quality of the handling of the iron itself. With the promulgation of the edict of 1876, prohibiting the wearing of swords, this art came to an end, but the skill of the Japanese ironworker may still be noted in numerous small decorative objects. (B.Ma.)

Gold and silver. Knowledge of metalwork seems to have spread to Japan by way of Korea during the Yayoi period (*c.* 250 BC–*c.* AD 250), but gold and silver never played any important role there. In the Nara period (AD 710–784), the Chinese T'ang style was dominant, and most of the goldwork and silverwork preserved in the Shōsōin at Nara was made under Chinese influence or by Chinese workmen. Silver vessels were used extensively among the aristocracy in the Heian period (794–1185), though not many of these vessels have survived, and both gold and silver were often used for applied reliefs or as inlay on bronze. In the later periods the use of precious metals was practically confined to inlays in bronze or iron, and the highest technical skill is shown by the artists who made the sword fittings. (B.V.Gy.)

AMERICAN INDIAN PEOPLES

Pre-Columbian. In pre-Columbian America, gold, silver, and copper were the principal metals that were worked, with tin, lead, and platinum used less frequently. When the Spaniards arrived in the New World in the 16th century, they found a wide range of well-developed technical skills in fine metalwork in Mexico, Costa Rica, Panama, and the Andean region. They had very little to offer the Indian smiths, who had already mastered the techniques of cold hammering and annealing; embossed decoration and chasing; pressing sheet gold over or into carved molds to make a series of identical forms; sheathing wood, bone, resin, and shell ornaments with gold foil; decorating with metal inlays and incrustation with jade, rock crystal, turquoise, and other stones; joining by clinching, stapling, and soldering; possibly drawing gold wire (in Ecuador and western Mexico); casting by the lost-wax method of solid and hollow ornaments, often with false filigree or false granulation decoration; wash gilding; and colouring alloys containing gold by "pickling" in plant acids. There was some regional specialization: hammer work in "raising" a vessel from a flat disk of sheet gold or silver reached its apogee in Peru (Figure 174), and lost-wax casting was highly developed in Colombia, Panama, Costa Rica, and Mexico. Miniature, hollow lost-wax castings of the Mixtec goldsmiths in Mexico have never been surpassed in delicacy, realism, and precision; and some

Metalwork skills of pre-Columbian Indians

D.T. Easby, Jr.

solid-cast frogs from Panama are so tiny and fine that they must be viewed through a magnifying glass to be appreciated. In Mexico bimetallic objects of gold and silver were made by two-stage casting; the gold part was cast first and the silver, which has a lower melting point, was then "cast on" to the gold in a separate operation. (A famous example is the pectoral of Teotitlán del Camino in the National Museum in Mexico City.) A silver llama in the American Museum of Natural History in New York City indicates that the Peruvian smiths had taken the first step toward cloisonné, the cloisons being filled with cinnabar instead of enamel.

A truly great technological and artistic triumph of the pre-Hispanic workers in Ecuador was the making of complex beads of microscopic fineness from an alloy of gold and platinum. This feat was achieved by sintering (to combine by alternately hammering and heating without melting) gold dust and small grains of alluvial platinum. (Platinum was a metal not to be used in Europe until 500 or 600 years later.)

Social standing of pre-Hispanic goldsmiths

As in other early cultures, the pre-Hispanic goldsmiths were a privileged and highly respected group, sometimes having their own patron deity such as Xipe Totec in Mexico or Chibchachun in Colombia. In Peru just before and at the time of the Conquest, the goldsmith (*kori-camayoc*) is said to have been a full-time government worker, who was supported by the state and who produced exclusively for the Inca. According to early Mexican picture writings (codices) and accounts of the Spanish chroniclers, the craft was hereditary, the secrets passed on from father to son.

The earliest examples of metalwork in the New World come from the "Old Copper" culture that flourished in the upper Great Lakes region of North America beginning about 4000 BC and continuing over the course of the next 2,000 years. The earliest goldwork is considerably later and consists of sheet-gold adornments with embossed decoration from Chongoyape, Peru, that were made sometime between 1000 and 500 BC. Casting seems to have begun in Mochica times early in the Christian Era in northern Peru, whence it is thought to have spread northward into Ecuador, Colombia, Panama, Costa Rica, and finally Mexico. Dating in the intervening areas is problematical, but it is generally accepted that fine metalwork in gold, silver, and copper did not reach the valley of Oaxaca in Mexico until about AD 900. Some finds in western Mexico suggest an earlier beginning date there and also that knowledge of the craft came by sea rather than overland from South America.

It is said that the Spaniards saw some pre-Columbian goldwork when they first arrived in Florida, but none seems to have survived. Some pre-European North American copper work, however, has survived. Metalwork was limited to a few regions in pre-European times. The "Old Copper" culture people took advantage of deposits of native copper (as opposed to smelting copper ores) to make tools and implements, and at a later period the Hopewell people extensively made copper ornaments and weapons, produced by cold hammering. A few copper bells also have been found in Arizona Hohokam sites, but these are imports that were manufactured in Mexico.

Southwest Indian. The famed Indian silverwork in the southwestern United States did not begin until 1853, when the craft was introduced to the Navajo by Mexican smiths. Although the origin is Mexican, certain ornament types and modes of decoration among the Navajo, as one scholar points out, trace back to earlier Indian silverworking in the eastern woodland, the plains, and the Rocky Mountains. It was not until 1872 that the first Zuni smith learned the craft from the Navajo. The Zuni had been carving turquoise long before the introduction of silversmithing, so it is not surprising that the most prominent characteristic of Zuni work is the extravagant use of turquoise insets. Navajo work is distinguished by die-stamped designs, whereas die work is very rare in Zuni silver. Authentic Navajo and Zuni pieces are still being made, but the tourist market has been flooded with cheap, commercial imitations.

Modern. The outstanding centre for fine handwork in silver in the Western Hemisphere is the little village of Taxco in the state of Guerrero, Mexico. An American resident, William Spratling, revived the ancient craft there in 1931 and trained a whole generation of talented silversmiths. (D.T.E.)

AFRICAN NEGRO PEOPLES

In Africa jewelry was fashioned from gold and silver as well as from nonprecious metals; heavy neck rings, anklets, and bracelets, for example, were made of forged iron or cast brass. Except for iron, metals were usually associated with prestige and/or leadership. Metals were also used for utilitarian objects such as Ashanti cast-brass weights (for weighing gold dust), which depict humans, other animals, vegetables, and geometric forms. The Nupe were excellent metalworkers, manufacturing a variety of vessels decorated with embossed designs.

Iron jewelry

Throwing knives of the Congo, often with punchwork designs, exemplify finely forged, abstract forms of iron weapons. Blacksmiths produced such ritual utensils as single or double gongs; Bambara, Dogon, and Lubi staffs topped with equestrian, human, and animal figures; and Yoruba and Benin shrine pieces containing mammal and bird forms.

Brass figure sculpture, which was cast by the lost-wax process, was usually the prerogative of royalty, as in Dahomey, and at Ife and Benin in Nigeria. Ife castings appear quite naturalistic and are among the finest sub-Saharan art. They are mostly hollow-cast heads, possibly used in ancestral rites. Benin "bronzes" were reported as early as the 16th century, but not until the 1890s did they become well-known in Europe. Local traditions indicate that the technique and the first caster came from Ife, in the 14th century. Predominant forms were heads representing deceased Benin kings (Figure 175), often supporting a carved ivory tusk. These, with other figurative castings as well as bells, were placed on altars that were dedicated to early kings. Figurative plaques were used as architectural decoration. Excellent thinly cast pieces, fairly close to the style of Ife, gave way to heavy, overdecorated pieces of the later 19th century.

Figure 175: Memorial king's head, bronze, from Benin, Nigeria, 15th century. In the Museum für Völkerkunde, Vienna. Height 25.5 cm.

Although metals appear throughout Africa, the cast "bronzes" (often brass) of Nigeria are particularly noteworthy. The earliest, from Igbo Ukwu, may be as early as the 9th century, those of Ife as early as the 12th century; Benin castings are later, and those of the Yoruba most recent. Lower Niger Bronze Industries is a term referring to one or more as yet inadequately studied traditions of uncertain date from various places in southern Nigeria. (Ro.Si.)

ENAMELWORK

Enamel, in art, is a vitreous glaze or a combination of vitreous glazes fused on a metallic surface. The general term enamels is applied to metal objects that have this material as the principal decoration.

Enamels have been used to decorate the surface of metal objects, perhaps originally as a substitute for the more costly process of inlaying with precious or semiprecious stones but later as a decorative medium in their own right. Whereas paint on metal has a short life and, even when new, is overshadowed by the brilliance of the polished metal, enamelling gives the surface of metal a durable, coloured, decorative finish. With the painted enamels of the Renaissance and the portrait miniatures of the 17th century, the technique reached its most ambitious and artistic form; for here the craftsman attempted to create a version of an oil painting, using a metal sheet instead of a canvas and enamels instead of oil paints. This medium undoubtedly has its limitations—few painted-enamel plaques of the Renaissance, for example, are much more than one foot square—but while oil paints on canvas eventually fade and darken, the colours of enamels are permanent. Relatively few creative artists of distinction have chosen to work in this medium, however, and it has tended to be purely decorative.

Few types of metal objects have not, at some period, been enriched with enamelled decoration. Throughout history, jewelry has been made more colourful by the application of enamels. Similarly, arms and armour, horse trappings, and even domestic items, such as mirrors and hanging bowls, were embellished with enamel decoration. Throughout the Middle Ages, both secular and ecclesiastical objects, such as chalices, cups, reliquaries, caskets, crosiers (a staff carried by bishops and abbots as a symbol of office), and spoons, were elaborately enamelled. With the advent of painted enamels in the Renaissance, tableware was completely covered with enamel, and painted-enamel panels were used to decorate the ceilings and walls of rooms in the châteaus of France. Following upon the invention of the domestic table clock and of the watch in the 16th century, enamelling became one of the most popular forms of decoration for the dials and cases; by the 18th century, items of the drawing room, such as snuffboxes, etuis (cases for small articles like scissors and needles), tea caddies, candlesticks, scent bottles, and thimbles, were frequently made of enamel.

Objects typically decorated with enamelwork

Among the objects decorated with enamels in east Asia are vases, incense vessels, teapots, suits of armour, and sliding doors.

This section treats the material, techniques, and history of enamelwork.

Materials and techniques

Enamel is a comparatively soft glass, a compound of flint or sand, red lead, and soda or potash. These materials are melted together, producing an almost clear glass, with a slightly bluish or greenish tinge; this substance is known as flux or frit—or, in France, *fondant*. The degree of hardness of the flux depends on the proportions of the components in the mix. Enamels are termed hard when the temperature required to fuse them is very high; the harder the enamel is, the better it will withstand atmospheric agencies, which in soft enamels first produce a decomposition of the surface and ultimately cause the breakup of the whole enamel. Soft enamels require less heat to fire them and consequently are more convenient to use, but they do not wear so well, especially if subjected to friction.

Clear flux is the base from which coloured enamels are made, the colouring agent being a metallic oxide, which is introduced into the flux when the latter is in a molten state. The brilliance of an enamel depends on the perfect combination of its components and on maintaining an equal temperature throughout its fusion in the crucible. The colour of many enamels is achieved by a change in the proportion of the components of the flux rather than by a change in quantity of the oxide. For example, turquoise-blue enamel can be obtained from the black oxide of copper by using a comparatively high proportion of carbonate of soda; in the same way, a yellowish-green enamel can be obtained from the same black oxide by increasing the proportionate amount of red lead.

Clear flux is also used to make opaque enamels; the addition of calx, a mixture of tin and lead calcined, renders translucent enamels opaque. White enamel is produced by adding stannic and arsenious acids to the flux, the quantity of the acid affecting the density, or opacity, of the enamel.

Preparation of the enamel

The heated enamel, after being thoroughly stirred, is usually poured out onto a slab and allowed to solidify into cakes of approximately four to five inches (10 to 13 centimetres) in diameter. For use, each cake must be pulverized into a fine powder with a pestle and mortar; the powder then has to be subjected to a series of washings in distilled water until all the floury particles are removed. The metal, on which the powdered enamel is to be spread, is cleansed by immersion in acid and water. All trace of the acid is then removed by washing and by drying in warm oak sawdust. After the wet powder has been spread on the metal, it is allowed to dry in front of the furnace before it is carefully introduced into the muffle of the furnace (a compartment protected from the flame), where it is heated to the point at which it fuses and adheres to its metal base. The firing of enamel takes only a few minutes, and the object is then withdrawn and allowed to cool.

The various techniques practiced by craftsmen in the past differ mainly in the methods employed in preparing the metal to receive the powdered enamel.

Cloisonné. In the cloisonné technique, thin strips of metal are bent and curved to follow the outline of a decorative pattern; they are then attached, usually soldered, to the surface of the metal object, forming miniature walls that meet and create little cells between them. Into these cells, the powdered enamel is laid and fused. After it has cooled, the surface can be polished to remove imperfections and to add to the brilliance. The cloisonné technique is particularly suited to objects made of gold, such as jewelry.

Champlevé. This process is the opposite of the cloisonné technique: instead of building up on the surface of the metal object, the surface is gouged away, creating troughs and channels separated by thin ridges of metal that form the outline of the design. The troughs are filled

Figure 176: Millefiore glass and champlevé enamel on a hanging bowl in the Sutton Hoo burial ship. Anglo-Saxon, c. 625–660. In the British Museum. Diameter 6 cm.
By courtesy of the trustees of the British Museum

with powdered enamel and fused. The champlevé technique requires a thick metal base and therefore is used on copper and other base metals (Figure 176).

Basse-taille. This technique is a sophisticated extension of the champlevé method, for again the metal surface has to be cut away and filled with enamel, but here there are two major differences. First, within the area that has been cut away to receive the enamel, a design or figural composition is chased (chiselled), or sometimes engraved, in low relief. Because the highest point of the relief is below the general surface of the surrounding metal, the enamel, which is level on its outer surface, lies in varying thicknesses over the modelled surfaces of the low relief. Second, because the coloured enamels used in this technique are translucent, the composition of the low relief shows through; and, since the metal used is normally gold or silver, the light is reflected back through the translucent enamelling, adding a brilliant tonal quality to the enamel, just as sunlight enhances the beauty of a stained-glass window. The effect of the reflected light varies according to the thickness of the enamel lying over the undulating surfaces of the low relief; consequently, an impression of plasticity and of three-dimensional modelling is created by the subtle variations in tonal strengths of the enamel colours, which range from bright highlights to the rich tones of the deep recesses.

Stained-glass window in miniature

Plique-à-jour. The plique-à-jour technique is designed to produce an effect of a stained-glass window in miniature through the use of translucent enamels. The technique is exactly the same as cloisonné enamelling except that the strips of metal forming the cells are only temporarily attached—not soldered—to a metal base to which the enamel will not stick. After the enamel is fused and sufficiently annealed, the metal sheet, usually aluminum-bronze, is removed with a few light taps, leaving a network of metal strips filled with enamel "windows." The enamels can be carefully polished to enhance their appearance.

Encrusted enamelling (émail en ronde bosse). Encrusted enamelling is the term used to describe the technique of enamelling the irregular surfaces of objects or figures in the round or in very high relief. Both opaque and translucent enamels are applied to these small-scale sculptural objects, which are usually made of gold (Figure 177). The great technical problem is to devise methods of supporting and protecting these objects during the firing. Frequently, plaster of paris is used to envelop parts of the object, leaving exposed only those parts on which enamel is to be applied and fused.

Hirmer Fotoarchiv München

Figure 177: "Goldenes Rössel," gold shrine with encrusted enamelling, French, *c.* 1403. Given to Charles VI of France by his queen, Isabella of Bavaria. In the pilgrimage church of Altötting, Germany. Height 62 cm.

Painted enamels. This technique differs fundamentally from the preceding five in that the various coloured enamels are not separated from each other by metal strips or ridges. Although these enamels are still applied in their wet, powdered state, the adjacent patch of coloured enamel is first allowed to dry to avoid one running into the other and so blurring the outline between them.

The metal generally used in this technique is copper. It is cut with shears into a plate of the size required and slightly domed with a burnisher or hammer, after which it is cleaned with acid and water. The enamel is laid equally over the whole surface both back and front, and then the object is fired. The first coat of enamel being fixed, the design is delineated by drawing with a needle through a layer of wet white enamel or any other that is opaque and most advantageous for subsequent coloration.

Grisaille enamels

In the case of grisaille enamels, the white is mixed with water, turpentine, spike oil of lavender, or essential oil of petroleum and painted over a dark-enamel ground. Light areas of the design are painted thickly; gray areas, thinly to allow the dark ground to tone the white pigment. The technique creates a strong contrast between light and shade, creating an impression of low relief. The scenes in grisaille are sometimes rendered more subtly by hatching, executed with a pointed tool or needle to reveal the dark enamel beneath.

In coloured painted enamels, enamel colours are spread over the grisaille treatment; when fired, parts of the surface are heightened by touches of gold, usually painted in thin lines, like hatchings. Other parts can be made more brilliant by the use of foil, over which the transparent enamels are placed and then fired.

History

ANCIENT WESTERN

The origins of the art of enamelling are uncertain. While there is archaeological evidence that glass was being made from the 3rd millennium BC in western Asia and from the 15th century BC glass vessels were undoubtedly being made in Egypt, there is no proof that enamelling on metal was practiced in either Asia Minor or Egypt until after the time of Alexander the Great (died 323 BC).

Mycenaean enamelling

Perhaps the origins of the art are to be found on Mycenaean metalwork of the 13th to 11th centuries BC. Six gold rings, excavated from a Mycenaean tomb of the 13th century BC at Kouklia (near Old Paphos), in Cyprus, are decorated with a cloisonné technique that suggests an intermediary stage between inlay and true enamelling. Scientific examination has shown that the different coloured enamels were not in the form of powder when they were inserted into the cloisons before being fired and fused together; rather they were in the form of fragments of coloured glass. Unfortunately, no report exists of any scientific examination of a more accomplished example of Mycenaean enamelling—the decoration on the gold sceptre found in a royal tomb at Kourion Kaloriziki, in Cyprus—but it is generally believed that this is true enamelling and datable to the 11th century BC.

If true enamelling existed in Mycenaean work, it would be reasonable to expect the technique to have been inherited by the Greeks and transmitted by them to the rest of Europe, perhaps by way of the colonies on the north shore of the Black Sea and in the south of Italy. Unfortunately, however, there is a long gap between the Mycenaean enamels and the Greek gold jewelry of the 6th–3rd centuries BC, which is sparingly enamelled, often having no more than touches of blue and white enamel enclosed by thin gold wire openwork (filigree).

Until recently the most ancient examples of enamelling outside Mycenaean art were said to be on ornaments discovered in a cemetery in the Kuban, close to the Caucasus, variously dated between the 9th and 7th centuries

Figure 178: "Pala d'Oro," altar screen of gold cloisonné enamel, Byzantine, 10th–12th century, reassembled with later additions in a Gothic frame in 1342–45. In St. Mark's Cathedral, Venice.

SCALA—Art Resource

BC; but the most important of these Kuban enamels, the famous Maikop belt buckle (the Hermitage, Leningrad) depicting a griffin attacking a horse, is now regarded by Russian experts as a forgery. Consequently, the earliest enamelling from south Russia may date from the 3rd or 2nd century BC.

A slightly earlier date is given to a number of excavated bronze objects of western European origin, which are said to bear the remains of cloisonné enamel decoration. Until this early Celtic material has been scientifically examined and proved to be true enamel as distinct from inlaid coral, cut stone (chiefly lapis), or coloured glass applied cold, theories about it remain open to question. At the present time it is a matter of conjecture what link, if any, may have existed between the enamellers in south Russia and those Celtic craftsmen who by the 3rd century BC, if not earlier, were using red enamel in place of coral inlay.

Celtic enamel decoration

During the Roman period, enamelling—both cloisonné and champlevé on bronze—was carried on almost entirely in those old Celtic areas that had become the northern provinces of the Roman Empire. It may well be to these provincial works that a passage from the works of Philostratus, 2nd century AD, refers. The author, describing a boar hunt at which the riders appear with horse trappings ornamented in bright colours, writes:

> It is said that the barbarians in the ocean [*i.e.*, the Celtic tribes] pour these colours into bronze moulds, that the colours become as hard as stone, preserving the designs.

This is a fair description of the process of champlevé enamel and suggests that the technique, in use in the British Isles, was not practiced at the time in Greece or Italy. Enamelled horse trappings such as Philostratus describes have been found in many places in the British Isles. This type of Celtic enamelling of the Roman period lived on in northwest Europe, particularly in Ireland, until as late as the 12th century. Some of its more striking effects seem to be derived from Roman glassmaking practices, particularly its use of millefiori glass, a mosaic of very thin glass rods of different colours and shapes fused together and then cut into thin sections, which the Celtic craftsmen fused into a ground of coloured enamel.

MEDIEVAL

Byzantine. The most dramatic development in the history of enamelling took place in the Byzantine Empire between the 6th and 12th centuries, a period during which only the cloisonné technique—almost exclusively executed on gold—was in use. At their zenith in the 10th–11th centuries, Byzantine enamellers created delicate, highly expressive miniature scenes in a great range of colours that shine like jewels. The masterpiece of this period is the altar screen "Pala d'Oro" in St. Mark's, Venice (Figure 178), believed to have been brought from Constantinople to Venice about 1105. The quality of Byzantine enamelling began to decline in the late 12th century.

Islāmic. There is no direct evidence that enamelling on metal was practiced at any Islāmic centre in western Asia. Scholars who argue that the technique of Byzantine gold-cloisonné enamelling originated in Syria before the 7th century AD can point to just one object on inconclusive stylistic considerations, associated with Umayyad Syria. Only one other enamelled object has survived with strong Islāmic connections: a dish with an Arabic inscription referring to an Artuqid Prince, who reigned AD 1114–44 (Figure 179). The enamel technique is cloisonné, but with bronze wires soldered onto a copper base. As no other examples have been found and as the inscription in Arabic indicates an imperfect knowledge of the language, it may be the work of a Byzantine craftsman working in the Artuqid kingdom.

Figure 179: Copper dish with cloisonné enamelling in turquoise, cobalt blue, red, yellow, and white; the Arabic inscription refers to the Artuqid prince of Āmid and Ḥiṣn Kayfā, Dāʾūd ibn Sugmān (reigned AD 1114–44). In the Tiroler Landesmuseum Ferdinandeum, Innsbruck, Austria. Diameter 23.11 cm.

Western European. As early as the 7th century, according to some scholars, Byzantine work was being copied by Lombard craftsmen in northern Italy; later it was imitated in Sicily and other parts of Italy—even perhaps in England, where the famous Alfred Jewel, made to the order of the English king Alfred the Great in the 9th century AD, shows strong Byzantine influence. In the Ottonian period (AD 936–1002), gold-cloisonné enamelling seems to have flourished in eastern France, and in the Rhineland, particularly among the goldsmiths working at Essen and in the workshops of Archbishop Egbert (AD 937–993) at Trier.

In western Europe cloisonné enamelling was abandoned in the 12th century, in favour of the champlevé technique executed on a base metal such as copper or bronze. This revival may have taken place first in Spain, in the valleys of the Rhine and the Meuse, or in France at Limoges; but, by the middle of the century, expert craftsmen in these centres—and in England—had established it as one of the foremost mediums for artistic expression in the Romanesque style. In the Mosan school, the famous 12th-century enamellers Godefroid de Claire at Liège and Nicholas of Verdun created champlevé enamelwork of unprecedented merit. The best work from Limoges was executed at the turn of the 12th–13th century; thereafter, the output was commercialized and standards fell steadily throughout the 13th and 14th centuries.

Basse-taille enamelling

In the late 13th century, gold and silver objects were again decorated with enamel but in a new technique, basse-taille enamelling.The earliest surviving dated example was made in Italy in 1290. Throughout the following century, Italian goldsmiths, particularly from Siena and Florence, produced pictorial masterpieces in this medium. The technique was especially favoured in Spain and France. No more accomplished example has survived than the "Royal Gold Cup" (British Museum), commissioned by the brother of the French king Charles V about 1380. The sides and the cover have scenes depicting the life and martyrdom of St. Agnes in the most glowing rich colours and elegant draftsmanship of the period. The great era of basse-taille enamelling ended with the Renaissance, though it remained popular in Spain and southern Germany, chiefly in Augsburg, to the middle of the 17th century.

15TH CENTURY TO THE PRESENT: EUROPEAN

Plique-à-jour and encrusted enamelling

Under the patronage of the courts of France and Burgundy in the late 14th and first half of the 15th centuries, goldsmiths devised new and more audacious methods of enamelling. Using translucent coloured enamels, they created the effect of stained-glass windows in miniature by the technique known as plique-à-jour. One of the loveliest pieces is the silver-gilt Merode beaker of Flemish or Burgundian origin, probably *c.* 1430–40, decorated with two bands of enamels set in tiny windows with Gothic tracery (Victoria and Albert Museum, London). Employing another technique, encrusted enamelling, they created both large-scale, three-dimensional compositions and miniature work to be worn as jewelry. Among the finest and earliest surviving examples is the Reliquary of the Holy Thorn (in the Waddesdon bequest in the British Museum): the Holy Thorn, set in a gem, is surrounded by the Last Judgment scene, in which all the figures (20) are enamelled, many of them being executed wholly in the round. The taste for this type of enamelled goldsmith work spread to all the courts of Europe; and, although the style changed several times, first from Gothic to Renaissance and then to Baroque, the essential extravagant toy-like quality remained. Of all the Renaissance goldsmiths who helped to create an international style, however, only Benvenuto Cellini wrote (*c.* 1560) a technical treatise on the subject.

Although the technique of painted enamels was probably first evolved by Flemish craftsmen about 1425–50 for the Burgundian court and perhaps developed by Venetian and north Italian enamellers between 1450 and 1500, the supremacy of the Limoges workshops was established by the beginning of the 16th century. For the next 100 years, French Mannerist art found talented expression in this medium, and, enjoying court patronage, the best Limoges enamellers strove to compete with other artists in decorating the rooms of royal palaces. Painting in grisaille was finally introduced at Limoges by about 1530–40 (Figure 180).

A new dimension was given to painted enamelwork about 1620–30 by a French goldsmith, Jean I Toutin of Chateaudun, and some rival craftsmen in Blois. Their achievement was to invent a highly skillful method for fine miniature painting in enamel colours on a white-enamel ground. Since the technique was admirably suited to the current enthusiasm for portrait miniatures, artists of distinction, such as Jean Petitot, were employed by Charles I of England and the French kings to work in this medium.

Miniature painting in enamel colours

With equal artistic skill, other French enamellers decorated items of jewelry, especially watchcases; and, by the second half of the 17th century, this craft had become centred on Geneva, where it continued to flourish into the 19th century. In England, particularly in the Midlands, the Continental style of painted enamelled "toys" was copied and produced on a large scale, but the technique of transfer printing on enamel was invented in England and brought to perfection at the Battersea (London) factory during 1753–56. The design was applied to the white-enamel ground by transferring to paper, and then to the surface to be decorated, an impression from an engraved metal plate that had been brushed with enamel colours. Throughout the 17th and 18th centuries, enamellers used the technique of fine miniature painting in enamels in Germany, Holland, England, and Russia in order to produce the "toys" of the fashionable world of society.

The technique called *en résille sur verre* flourished for only about 40 years (*c.* 1600–40), and few examples have survived. Yet it required an exceptional degree of skill. The technique consists of cutting the design in a medallion of glass, usually coloured, lining the incisions with gold and filling them with variously coloured enamels. The exponents of this kind of enamelling were mainly French.

Although surviving examples are rare, there is a dis-

tinctive group of brass objects, mainly candlesticks and andirons, which have green, blue, or white opaque enamelling. These objects were made in 17th-century England (perhaps in Sussex).

Most of the early enamelling techniques have continued to be used by goldsmiths in modern times—from the Parisian makers of gold snuffboxes in the 18th century to Carl Fabergé at the beginning of the 20th. Art Nouveau jewellers, such as René Lalique, and modern artists, such as Georges Braque, Georges Rouault, and Gerda Flockinger, have kept alive the craft of enamelling and added to the multiplicity of its ingenious effects. (H.Ta.)

CHINA

Enamels do not appear to have reached China until long after they were found throughout Europe. All authorities are agreed as to the Western origin of the art, which in all probability was introduced into China by traders or by travelling craftsmen. Although by the 5th century AD the Chinese were informed as to the production of glass—an essential material for the making of enamels—and were already highly skilled in the working of bronzes and other metals, there is no evidence that the art of enamelling was practiced before the T'ang dynasty (618–907). There is in the Shōsō-in (principal storehouse) at Nara, in Japan, a silver mirror, the back of which is decorated in cloisonné (Figure 181). It is generally agreed that the mirror is of Chinese origin, dating from the T'ang dynasty, as is certainly the case with many other objects in the collection.

Earliest known enamelwork

At present, this is the only known Chinese enamelled ware made before the 14th century; but it can be safely assumed from this piece that the art of cloisonné was developed to a respectable height in the T'ang dynasty. It appears that cloisonné work was well established in China at the end of the 14th century and that Byzantine work of similar character was also so well known as to invite comparison with the native product. The former may well have served as an example for Chinese craftsmen. As one scholar points out:

> The workmanship presents occasionally . . . striking resemblances with certain enamels of the Byzantine school; the mixture of different enamels inside the wall of the same cell, the employment of gold incrustations in the treatment of the fingers and the hands, etc.

Active trade and cultural intercourse between the Near East and China during the Yüan (Mongol) dynasty must have been the reason for this revival of enamelwork, which then flourished through the Ming and Ch'ing dynasties (1368–1644 and 1644–1911/12, respectively).

Chinese enamels fall into three categories—cloisonné, champlevé, and painted. In none does the technique vary appreciably from that employed in Western countries.

Cloisonné. The earliest example of cloisonné enamel that can be authentically associated with east Asia is the silver mirror in the Shōsō-in mentioned above. Its cloisonné back is decorated in a design of a six-petalled blossom in three layers, the tips of the outer rows of petals forming 12 points of the mirror. The piece is regarded as a T'ang dynasty work. Apart from this, the sequence of known Chinese enamels begins in the Yüan period, and the earliest recorded marks belong to the reign of the last emperor of that dynasty (1333–68). The great period of production is certainly that of the Ming dynasty, which followed.

Ming enamels

The mark most commonly found within this period is that of the Ching-t'ai reign (1449–57). The Ming enamels, bold in design with fine depth and purity of colour, were never surpassed in later epochs. The two shades of blue, a dark-lapis-lazuli tone and a pale sky blue with a very slight tinge of green, are particularly excellent. The red is of dark-coral tint, and the yellow full-bodied and pure. Greens derived from copper are sparingly used. Black and white are the least successful, the former shallow and dull, the latter clouded and muddy. As fine as the Ming enamels are, however, there is an imperfection of technique, close examination revealing minute pitting in the enamels, which was caused by inadequate packing of the material, and some lack of polish in the surface. These technical defects, however, do not appreciably detract from the great artistic value of the Ming enamels (Figure 182).

Figure 181: Mirror back, cloisonné enamel on silver, Chinese, T'ang dynasty, 9th century. In the Shōsō-in, Nara, Japan. Diameter 18.7 cm.

A great revival of art industries took place under the patronage of the emperor K'ang-hsi (1661–1722), who, in 1680, established a series of imperial factories. He commissioned sets of incense vessels of cloisonné enamel for presentation to the numerous Buddhist temples founded under his auspices in the neighbourhood of Peking, as well as other objects for the honorific gifts that were characteristic of his enlightened reign. The enamels produced during his time are marked by an improvement in technical quality as compared with those of the Ming period; to

Figure 182: Ming dynasty vase, cloisonné enamel, Chinese, *c.* 1500. In the British Museum. Height 41.5 cm.
By courtesy of the trustees of the British Museum

a considerable extent they also retained the finer qualities of the Ming wares. In many cases the forms of ancient bronze vessels were revived and enriched with enamels.

The style of this reign persisted during that of K'anghsi's successor, Yung-cheng (1722–35), while the long rule of Ch'ien-lung (1735–96) was marked, in enamel as in the case of many other industrial arts, by a further perfection of technique but by a loss of much of the vigour of design and breadth of execution that distinguished the products of earlier periods. Modern enamels, although they are primarily imitations of older work, are more hurriedly made and therefore not so well finished as the older work.

Champlevé. Some of the most ancient enamel examples extant belong to this class, and examples employing both champlevé and cloisonné are not uncommon.

Although the opaque enamels were more common, Chinese artisans occasionally used translucent enamels on a silver or gold base. The cloisonné back of the silver mirror in the Shōsō-in, for example, is decorated with transparent enamels, but important pieces such as this are rare. This technique more often appears in Chinese jewelry.

Painted enamels. The painted enamels of China, generally known, from the principal seat of their manufacture, as Canton enamels, are practically identical in technique with the Limoges and other painted enamels of Europe. Specimens of the latter are known to have been taken to China by the missionaries of the late 17th and 18th centuries; they not only exercised direct influence on the Chinese ware but also, in some cases, were copied. Representations of European subjects, copies of engravings and armorial decorations, are also found. Painted enamels are termed by the Chinese *yang-tz'u* ("foreign porcelain"), the palette of colours used being the same as with enamelled porcelain, whose decoration under foreign influence is called *yang-ts'ai* ("foreign colours"). A ground of opaque enamel, generally white, is laid on the copper, and on this the colours are superimposed and fired. The best period of this art was the 18th century. Although imitations have continued to be made, nothing of real quality in this style was produced after the termination of the reign of Ch'ien-lung in 1796. The method has always been looked upon by the Chinese as alien in taste; in fact, a great part of the Canton enamels were made for export, not only on European commission but also for clients in India, Persia, and several other Asian countries.

Canton enamels

JAPAN

The art of enamelling in Japan may date back to the 7th century. One enamelled metal piece, discovered in a tomb near Nara, probably from the 7th century, seems to be of Japanese origin. The civic Taihō code, compiled in the 8th century, provides one official to be in charge of founding metals and "painted glass decoration." Subsequently, however, this art seems almost to die out until the 17th century. When Dōnin Hirata I (1591–1646) made enamelled wares, having learned the technique from Koreans, his art was highly appreciated by Tokugawa Ieyasu, then the shogun of Japan, under whose patronage Hirata worked in Kyōto. There is a suit of armour with enamelled metal fittings ascribed to him, as well as enamelled metal fittings decorating sliding doors and lintels in the Katsura Palace, Kyōto. His family continued the trade until the late 19th century, making use, on a small scale, of both the cloisonné and champlevé methods. There was no further development of importance until Kaji Tsunekichi (1803–83) and his pupils established in Nagoya a successful manufacture of cloisonné, which obtained a considerable vogue, especially among foreigners.

Figure 183: Panel of Mt. Fuji seen through clouds, done in lineless cloisonné by Namikawa Sōsuke, 1893. In the Tokyo National Museum. 63 cm × 113.6 cm.
By courtesy of the Tokyo National Museum

While Kaji used brass cloisons and opaque enamel colours only, his successors used silver cloisons and succeeded in making both transparent and translucent enamels. They further modified the cloisonné process with remarkable ingenuity and produced work of great interest. First, they reproduced in minutely detailed cloisonné work realistic pictures, of trees and flowers, for example. This effort led them in the 1880s to produce lineless cloisonné enamels, which have all the beauty and brilliance of true cloisonné, with thick layers of enamel colours, but which, showing no trace of cloisons, permit a gradation of colours as in the less clear and brilliant painted enamels. The effect was achieved by taking off the cloisons before each firing, the process being repeated at least three times. The artists working for the factory of Namikawa Sōsuke of Tokyo in the late 19th century were most successful in this technique (Figure 183). Another Namikawa of Kyōto worked in true cloisonné. The factory of Jubei Ando of Nagoya has produced more variations. These developments have carried the art of enamel very far from the old traditions; while the skill and ingenuity of technique they evince may be appreciated, there is a danger of losing the artistry peculiar to the art of enamelling. (Ed.)

Lineless cloisonné

LACQUERWORK

Lacquerwork consists of certain metallic and wood objects to which coloured and frequently opaque varnishes called lacquer are applied. The word lacquer is derived from lac, which is the basis of some lacquers. The lacquer of East Asia, China, Japan, and Korea must not be confused with other substances to which the term is generally applied; for instance, the lac of Burma, which is the gummy deposit of an insect, *Coccus lacca,* and the various solutions of gums or resin in turpentine of which European imitations of Eastern lacquer have been and are concocted.

This section deals with the materials, techniques, and history of artistic lacquer ware.

Techniques

OBTAINING AND PREPARING LACQUER

Lacquer, as used in China and Japan, is a natural product, the sap of a tree, *Rhus vernicifera;* subject to the removal of impurities and excess water, it can be used in its natural state, though it was frequently adulterated. The tree, which is indigenous to China and has certainly been cultivated in Japan at least since the 6th century AD, is tapped at about the age of 10 years, when lateral incisions are made in the bark and the running sap is collected during the months of June to September. Branches of a diameter of one inch (about three centimetres) or more are also tapped, the bark having first been removed. Smaller branches are cut off and soaked in water for 10 days, and the sap is collected, producing a lacquer (*seshime*) of particular quality, used for special purposes. These processes kill the tree, but the wood, when of sufficient size, is of some use for carpentry. From the roots five or six shoots spring up, which become available for the production of lacquer after about six years, and the operation can be thus continued for a considerable length of time before the growth is exhausted. The Chinese and Japanese methods

Collecting the sap

are practically identical in this respect, but the cultivation of the tree does not seem to have been as systematic in China as in Japan.

The sap is white or grayish in colour and about the consistency of molasses. On exposure to the air it turns yellow-brown and then black. It is strained through hempen cloth to remove physical impurities, after being pounded and stirred in shallow wooden tubs to give it uniform liquidity. It is then slightly heated over a slow fire or in hot sunshine, and stirred again to evaporate excess moisture, and stored in airtight vessels.

The basis of lacquer ware, both in Japan and in China, is almost always wood, although it was also occasionally applied to porcelain, brass, and white metal alloys. In some instances, objects were carved out of solid lacquer. The wood used, generally a sort of pine having a soft and even grain, was worked to an astonishing thinness. The processes that follow are the result of extraordinary qualities of lacquer itself, which, on exposure to air, takes on an extreme but not brittle hardness and is capable of receiving a brilliant polish of such a nature as to rival even the surface of highly glazed porcelain. Moreover, it has the peculiar characteristic of attaining its maximum hardness in the presence of moisture. To secure this result, the Japanese place the object in a damp box or chamber after each application of lacquer to the basic material (wood, etc.). The Chinese are said (in an account of the industry dating from 1621–28) to use a cave in the ground for this purpose and to place the objects therein at night in order to take advantage of the cool night air. It may, indeed, be said that lacquer dries in a moist atmosphere.

Hardening with moisture

APPLICATION

The joiner's work completed and all knots or projections most carefully smoothed away, cracks and joints are sealed with a mixture of rice paste and *seshime* lacquer, until an absolutely even surface is obtained. It is then given a thin coat of *seshime* lacquer to fill up the pores of the wood and to provide a basis for succeeding operations, which may number as many as 20 or 30 or more, of which any one of the following may be taken as typical. On the basis, as above described, is laid a coat of lacquer composition which is allowed to harden and is then ground smooth with whetstone. Next comes a further coat of finer composition, in which is mixed some burnt clay, which is again ground and laid aside to harden for at least 12 hours. On this is fixed a coat of hempen cloth (or, rarely in Japan but more often in China, paper) by means of an adhesive paste of wheat or rice flour and lacquer, which needs 24 hours at least to dry. The cloth is smoothed with a knife and then receives several successive coats of lacquer composition, each demanding the delay necessary for hardening. On this is laid very hard lacquer, requiring a much longer drying interval, afterward being ground to a fine surface. Succeeding coats of lacquer of varying quality are now laid on, dried, and polished.

This preliminary work, requiring for artistic lacquer at least 18 days, produces the surface on which the artist begins his task of decoration. A large number of processes have been at his command, especially in Japan, but the design was first generally made on paper with lacquer and transferred while still wet or drawn directly with a thin paste of white lead or colour. In carrying it out the artist used gold or silver dust applied through a quill, a bamboo tube, or, for equal distribution, a sieve. Larger fragments of the precious metals were applied separately by hand, with the aid of a small, pointed tool. In one typical instance approximately 500 squares of thin gold foil were thus inserted within one square inch (six square centimetres). These processes each entailed prolonged hardening periods and meticulous polishing. Relief was obtained by modelling with a putty consisting of a mixture of lacquer with fine charcoal, white lead, lampblack, etc., camphor being added to make it work easily. Lacquer was sometimes engraved, both in China and Japan.

CHINESE CARVED LACQUER

The carved lacquer of China (*tiao-ch'i*), which was imitated but never equalled in Japan (as the Chinese have never reached the perfection of the Japanese gold lacquer ware), needs particular notice (Figure 184.) In this the lacquer was built up in the method described above, but to a considerable thickness; when several colours were used, successive layers of each colour of uniform thickness were

Use of successive layers of different coloured lacquer

Figure 184: Imperial Chinese throne of the Ch'ien-lung emperor (1736–96), red lacquer carved in dragons and floral scrolls, Ch'ing dynasty. In the Victoria and Albert Museum, London. 1.19 m × 1.26 m × 91 cm.

arranged in the order in which they were to predominate. When the whole mass was complete and homogeneous, it was cut back from the surface to expose each colour as required by the design. When the lacquer was cold and hard, the carving was done with a V-shaped tool kept very sharp. The cutting was done with amazing precision—no correction of faults was possible, for each layer had to be exactly and accurately reached and the final result precisely foreseen from the beginning of the work. The red lacquer (*t'i-hung*), so well known and justly appreciated, was coloured with cinnabar (red mercuric sulfide). Other colours include a deep and a lighter olive-green, buff, brown, black, and purple (aubergine).

JAPANESE PROCESSES

In Japanese lacquer, the following are the chief processes used: *nashiji* (pear skin), small flakes of gold or silver sunk to various depths in the lacquer; *fundame,* fine gold or silver powder worked to a flat, dull surface; *hirame,* small, irregularly shaped pieces of sheet gold or silver placed on the surface; *togidashi,* the design built up to the surface in gold, silver, and colours with many coats of lacquer and then polished down to show them (Figure 185); *takamakie,* decoration in bold relief; *hiramaki-e,* decoration in low relief: *rō-iro,* polished black; *chinkin-bori,* engraved lacquer; *kirikane,* square dice of sheet gold or silver, inserted separately on the surface; and *raden,* inlaid shell and metal. From the earliest recorded times shell was used in the adornment of lacquer in China as well as in Japan, being inlaid on the surface in patterns as well as in small squares like *kirikane* and dust. For this purpose various shells were used, mother-of-pearl (for larger work), nautilus, pear shell, sea-ear (*Haliotes,* Japanese *Awabi*) and *Turbo cornutus* (Japanese *Sazae*). For a very charming form, called *laque burgauté,* the iridescent blue and green shell of the sea-ear was delicately engraved with gold and silver as early as the Ming period (1368–1644) and also in Japan. Chinese lacquer was also inlaid with jade, malachite, coral, soapstone, ivory, porcelain, and other substances.

Laque burgauté

Historical development

CHINA

The use of lacquer in China goes back traditionally to legendary times. A late Ming manuscript, the *Hsiu shih*

Figure 185: Japanese box with "ardent lover" theme in *togidashi* on a *rō-iro* background, signed Katsukawa Shunshō, early 19th century. A young woman takes black tooth stain from a bowl held by her attendant and squirts from her lips the characters for "perseverance in love." lu, states that it was first employed for writing on bamboo slips, then for utensils for food, made of black lacquer, and subsequently for vessels for ceremonial use, of black with red interiors (Figure 186). During the Chou dynasty (1111–255 BC) it served for the decoration of carriages, harnesses, bows and arrows, etc., and was the subject of official regulations. At this time, gold and colours are said to have come into use. About the 2nd century BC buildings were decorated with lacquer, as were musical instruments. Under the Han dynasty (206 BC–AD 220) further development took place. Pot covers of paper covered with lacquer, found near Port Arthur, are attributed to this period.

Of the lacquer of the T'ang dynasty (618–907) more reliable information is available, for the collections preserved in the Hōryū-ji in Japan, founded AD 607, and those assembled by the Japanese emperor Shōmu (724–748), deposited after his death in the Imperial treasury (Shōsō-in) at Nara, contain many objects of Chinese origin; in particular, musical instruments with inlay of cutout figures of gold and silver inserted on the surface, covered with lacquer, which was then rubbed down until the metal ornaments were again visible.

Under the Sung dynasty (960–1279) the industry further developed, and the use of gold and silver lacquer in the utensils made for the palace is particularly recorded. The chief centres of manufacture were Chia-hsing and Su-chou. A lacquer box of the early Sung period, probably once of rhinoceros-horn colour, black and red, with gold dust and silver wire, is one of the very few known examples of the period. Toward the close of the period (*c.* 1220) it is stated that lacquer wares were exported from Ch'uan-chou, Fukien to Java, India, Persia, Japan, Mecca, and other places. Chinese writers record the existence of carved red lacquer during the time of the Yüan dynasty (1206–1368) as well as of pierced ware and that inlaid with shell.

Ming lacquerwork

Of the state of the industry under the Ming dynasty (1368–1644) there are contemporary Chinese descriptions; for instance, in the *Ko ku yao lun,* published in 1388, the *Ch'ing pi-ts'ang,* published in 1595, and the *Hsiu shih lu,* which has been handed down in manuscript. This last work was written by a celebrated lacquerer, Huang Ch'eng, and bears a preface by Yang Ming, another lacquerer, dated 1625. The work itself was probably written towards the end of the 16th century. From these works one can ascertain the excellence of the carved lacquer made during the reigns of the Yung-lo (1402–24) and Hsüan-te (1425–35) emperors. Examples of carved lacquer that can be attributed to both these reigns are extant. They are bold in design and free from the superabundance of small detail that characterized later productions; the colour also is generally deeper and richer than that of the 18th-century pieces. In the 16th century there were special factories for carved lacquer at Ta-Li in Yünnan, which also produced spurious imitations. Lacquer with designs painted in gold outlines were made, early in the Ming dynasty, at Nanking and afterward at Peking, and lacquer inlaid with mother-of-pearl was made at Chi-chou in Kiangsi. In the reign of Hsüan-te, lacquer decorated in sprinkled gold was introduced from Japan and excellent copies were made by Chinese lacquerers. Toward the end of the Ming dynasty there was a decline in lacquer manufacture as a result of the troubles accompanying the fall of the last Ming emperor.

The first and perhaps the greatest of the Manchu emperors, K'ang-hsi (1661–1722), revived the lacquerwork industry in 1680, when he established a series of 27 workshops for artistic handicrafts in the precincts of the palace at Peking. Carved lacquer was, however, also made at Canton, Su-chou, and Foo-chow; and the Jesuit Louis le Comte, who arrived in China in 1687, gave a good account of the flourishing state of the industry at that time. In this connection it is worth noting that the period of K'ang-hsi was that which saw the first considerable importation of lacquer ware (and other objects of industrial art) into Europe. This led to the development of imitation lacquer applied to furniture and other objects, which were conspicuous features of the chinoiserie craze of the late 17th and 18th centuries. A screen, *c.* 1700 in the collections of Earl Spencer and R. Freemer Smith, Esq., for example, was made by command of K'ang-hsi for presentation to the Holy Roman emperor Leopold I, whose badge, the double-headed eagle, is incorporated in the design. Carved lacquer of this period, though far from negligible, hardly attains to the rich colour, breadth, and simplicity of that of the Ming period.

Importation into Europe

In technique the K'ang-hsi ware shows an advance and is generally free from the small cracks too often found to have developed in the Ming products. The perfection of this quality, apart from other considerations, is found in the lacquer ware of Emperor Ch'ien-lung (1735–96), a devoted admirer of this art, who employed it on a large scale for the furniture and fittings of his palaces (Figure 184), as well as for ceremonial and commemorative gifts. The workmanship of objects made under his auspices is brilliant in the extreme, but the colour is hard as compared to earlier work, and the design tends to a somewhat stereotyped formalism.

Still, the 18th century can hardly be called a period of decadence in the decorative arts of China: the superb execution of its productions, a characteristic that commands admiration, redeems it from adverse criticism. The downward course began in the 19th century, with loss of originality and a falling off, due to adulteration, in the quality of the material. What was left of the Imperial fac-

tories was burnt in 1869, and, though carved red lacquer was made after that date, the industry had already ceased to have artistic importance.

JAPAN

Although the earliest reference to the manufacture of lacquer accepted by all Japanese authorities is a code of law (known as Taihō code) dated 701, there can be no doubt that the manufacture was brought to Japan from China via Korea at the time of the introduction of Buddhism in the middle of the 6th century. At the same time, according to tradition, the Chinese lacquer tree was introduced. The earliest piece of lacquer known today that is accepted as having been made in Japan is the Tamamushi Shrine in the Hōryū-ji, which is attributed to the 7th century. This piece shows strong Korean influence. Many fine pieces of the late 7th and the 8th centuries, inlaid in gold, silver, or mother-of-pearl, of Chinese origin, have been preserved in the Shōsō-in, as already mentioned in the section above on Chinese lacquer. But there is one piece in the Shōsō-in, a sword-scabbard of black lacquer decorated in gold, formerly belonging to the emperor Shōmu (724–748), that is undoubtedly Japanese. This is listed in an old catalog dated 756. There are also two arrows in the Tokyo National Museum that belong to the same period. These can be regarded as the real beginnings of a Japanese style in lacquer.

The emperor Kammu (781–806) removed the capital from Nara to a new city, Heian-kyō—the modern Kyōto; and an increased luxury in the style of living brought about further developments in the art, especially in the use of gold lacquer, largely because of the spread of Buddhistic influence. This period, however, saw the beginnings of a Japanese national style as distinct from the Chinese methods and manner, imported by Buddhist missionaries. Lacquer was used at this time in the decoration of important buildings, and inlay of shell also became popular. The organization of the industry was extended, and, as early as 905, sumptuary edicts began to be issued regulating the dimensions and quantities of material to be used in the domestic utensils—chiefly of black or red polished lacquer—which now began to come into general use. From this time, it is no exaggeration to say that, to a considerable extent, lacquer filled the place occupied in China by ceramic wares. A remarkable development of this period that must not be overlooked was the production of statuary of considerable merit, made with lacquer composition (*kanshitsu*), a process derived from China but carried to a high standard in Japan for a brief period, until it was superseded by wood sculpture (Figure 187). Some few authentic examples remain of the fine lacquer of the Heian period, notably a case for Buddhist scriptures in the Ninna-ji at Kyōto, made at the beginning of the 10th century, which bears an inscription dated 919. The case is in black lacquer, sprinkled with gold dust and with a pattern of flowers, clouds, birds, and Buddhist winged genii in gold and silver *togidashi*.

Production of statuary

During the Kamakura period (1192–1333), in spite of the disturbance caused by the famous struggle between the Minamoto and Taira clans and the establishment of the feudal shogunate at Kamakura, which gives its name to the period, the art of making fine lacquer continued to progress under the patronage of the Fujiwara family, who maintained the Imperial court at Kyōto with ever increasing luxury. Marked features of this time are improved methods of inlay of precious metals and shell and, especially, an attractive form of design in which beautifully written poems are interwoven with the pattern (*ashide*). The process called Kamakura-*bori*, carved wood thickly lacquered with red or black, also dates from this period and continued to flourish for another two centuries or so. During this epoch occurred the beginnings of the characteristic Japanese treatment of landscape and flower subjects in design, generally in flat gold lacquer with *nashiji* and pewter inlay.

Muromachi lacquerwork

The Muromachi period (1338–1573) saw a further technical and artistic development, largely under the patronage of the shogun Ashikaga Yoshimasa (reigned 1443–73). He gave great impetus to the tea and incense ceremonies, the latter of which brought about a whole series of new applications of the art because of the exquisitely wrought small utensils required by that ritual. The ostentatious simplicity of the Zen sect of Buddhists was displayed in the use of black lacquer of the first quality with little or no ornament. Excellent work in shell inlay was also a characteristic of the time. The gold lacquer of the Muromachi craftsmen gained so great a reputation in China that artisans from that country went to Japan to learn the methods by which it was produced, though they seem to have had little success in introducing it into their own country. Among the leading Japanese craftsmen of the period may be mentioned Kōami Dōchō, Taiami, Seiami, and Igarashi Shinsai, but attribution of specific works to them is largely a matter of conjecture.

The civil wars which continuously infested Japan during the later Middle Ages checked the growth of the industry for a while, but the short Azuchi-Momoyama period (1574–1600) that followed saw at least the work of one of the greatest of Japanese artists in lacquer, Honami Kōetsu. He was the founder of a striking and original style of ornament, essentially national in character. His designs were bold and simple in detail, generally executed in high relief with masses of shell or metal inlay. The great feudal lord Toyotomi Hideyoshi (died 1598), who secured the peace of the country with a strong hand, was an enthusiastic patron of the arts, and under his patronage a real revival took place. When he died, his widow erected the Kōdai-ji at Kyōto, in which distinctive lacquer decoration called *tata maki-e (Koda-ji maki-e)* was used. This temple still contains examples of this ware that were presented by her.

The Edo school

In 1603 began the rule of the Tokugawa shogunate, which continued without a break until the restoration of the Imperial family to actual power in 1867. The first of the line, Ieyasu, established at Edo (the modern Tokyo) the great school of lacquer artists that is responsible for almost the whole of the artistic ware known outside Japan. Technical processes were still further developed with additions such as engraved lacquer (*chinkinbori*) derived from China, carved red and black lacquer from the same source, and the so-called *somada* ware of shell inlay of black, different in character from the Chinese *laque burgauté* already mentioned above.

This period also saw the introduction of the now well-known *inrō*, or portable medicine case, worn on the girdle and an indispensable addition to the national costume so long as the latter was uncontaminated by Western influence. An *inrō* consisted, as a rule, of from two to five

Figure 188: Tokugawa period writing box of black lacquered wood decorated in gold paint, inlaid lead, and pewter. Attributed to Ogata Kōrin (*c.* 1658–1716). In the Seattle Art Museum, Washington. 23 × 22 × 8 cm.

compartments, beautifully fitted into each other and held together by silken cords running along each side, secured by a bead (*ojime*) and kept in place on the sash by a kind of toggle (*netsuke*), sometimes of lacquer but more often of cunningly carved wood, ivory, bone, or other material. On this class of work was lavished some of the finest artistry of the Japanese craftsmen, and the convenient size and intrinsic charm of these dainty utensils (originally, perhaps, made for seals) have caused them to be much favoured by collectors.

Chinese influence on Tokugawa lacquerware

The earlier years of the Tokugawa period saw a considerable Chinese influence in the design of lacquer, especially in *inrō;* but the work of the greatest Japanese lacquer artists, Ogata Kōrin (Figure 188), followed and extended in the late 17th century the style originated by his master, Kōetsu. Ritsuō and Hanzan in the 18th century maintained this tradition, and a considerable revival of the style took place in the early years of the 19th century, when memorial volumes of the designs of the great master were published. To the latter period belong not a few objects which have been accepted as the original work of Kōrin himself. The more formal school of lacquerers included Kōami Chōgen (1572–1607) and Komo Kitō-ye, who was appointed court lacquer artist to the shogun Iemitsu in 1636 and died in 1674. One of the most important lacquerers of the Kōami family was Kōami Nagashige (Figure 189), whose masterpiece, consisting of three connected cabinets with numerous writing cases, paper cases, and toilet cases, a mirror stand, and other accessories, was completed in 1639. It was made for the dowry of Tokugawa Iemitsu's eldest daughter, on her marriage to Mitsumoto, prince of Bitchū, whose coat of arms is affixed to all the pieces. The lacquer is now in the Tokugawa Art Museum, Nagoya. As did other craftsmen in Japan, lacquer artists followed the practice of transmitting their names to sons or selected pupils. Thus, there were ten generations of the family of Yamamoto Shunshō, who died in 1682, aged 63. The Kajikawa family continued the tradition of its founder well into the 19th century, and the same must be said of Shiomi Masanari in the 18th century, whose work was notable for the quality of the rubbed-down gold and colour lacquer called *togidashi.*

The Genroku period (1688–1703) saw, perhaps, the ultimate perfection of style and technique; but the work of the later 18th and, to some extent, of the early 19th centuries has many exquisite qualities. The later periods were characterized by more elaborate detail, but adulteration of the gold with bronze and other metallic powders was often prevalent. A fiery brown tint of the *nashiji* is a certain mark of quite late date. Nevertheless, there is plenty of good work of the 19th century, and to this period belongs the last of the great artists of the industry, Shibata Zeshin, whose work bears comparison even with some of the greatest of his predecessors, both in technique and in design.

Modern industrial conditions, however, have practically killed this ancient and beautiful art. It would not have survived so long had not the country been closed to alien influences for two and a half centuries. (E.F.S.)

EUROPE

Although East Asian objects of art were taken to Europe in considerable quantity during the 16th century, it was not until after 1600 that a real trade with China grew up, fostered by the East India companies of the Netherlands, England, and France. Porcelain and lacquerwork then became so fashionable that European craftsmen undertook to make their own. The secret of porcelain manufacture was discovered shortly after 1700, and by that time the imitation of lacquer had become established in various parts of Europe. Jesuit missionaries had cooperated with scientists and master craftsmen to create formulas, and a small body of writing had appeared, which was to be augmented in the 18th century—the golden age of European lacquer.

Origins of the European lacquerwork industry

Among the earliest surviving examples of this art is the ballot box of the Saddlers Company (Figure 190). Information on the lacquer process seems first to have been published by the Italian Jesuit Martin Martinius (*Novus Atlas Sinensis,* 1655). John Stalker and George Parker's *Treatise of Japanning and Varnishing* (London, 1688) was the first text with pattern illustrations. The English term japanning was inspired by the superiority of Japanese lacquer, which Stalker found "... in fineness of Black, and neatness of draught ... more beautiful, more rich, or Majestick" than the lacquer of other places, which came to be known as "Indian" or "Bantam" work.

In France, on the other hand, *ouvrage à la Chine* was the term for the imitation of lacquer practiced at the Gobelins factory in Paris from 1672. By the end of the century Berlin had become another centre of experimentation, from which a Fleming, Jacques Dagly, brought secrets that were to lead to the 18th-century innovations of the Martin brothers: Guillaume, Simon, Étienne, Julien, and Robert. They created the lustrous *vernis Martin,* which was praised by Voltaire. The Martins decorated rooms at Versailles, and Robert's son Jean Alexandre worked for Frederick the Great II at Potsdam. French lacquer was further improved through new information provided by the *Mémoire sur le vernis de la Chine,* which the French missionary Pierre d'Incarville wrote in 1760 and which appeared as an appendix to *L'Art du peintre, doreur, vernisseur* of Jean-Félix Watin (1772), the most precise account of lacquerwork that appeared in the 18th century. In this book Watin examined the recipes of his predecessors and recommended the best formulas for lacquering objects to be used indoors, such as furniture, and outdoors, such as carriages. Although nothing could equal the excellence of Oriental

Figure 190: Ballot box of the Saddlers Company, 1619. In the collection of the Saddlers Company, London. 45 × 44 × 33 cm.

resins, he determined that sandarac from Western juniper trees was the best substitute. This, together with various gums dissolved in alcohol and turpentine and mixed with bitumens, produced the different varnishes Watin relied upon. His book gives detailed instruction for preparing the wood, covering it with cloth, varnishing this with from eight to 20 coats, polishing the surface, drawing and painting the designs, and making relief decorations. The best results of this process (*e.g.*, an 18th-century commode attributed to René Dubois; Figure 191) were never as hard and brilliant as real Oriental lacquer, but they provided an admirable substitute; on occasions it is not easy to distinguish them, especially when East Asian designs were imitated.

Introduction of European motifs

The chief interest of European lacquer of the 18th century lies, however, in the fact that it was not a purely imitative art, as it had been at its beginning. Until about 1720, European craftsmen sought to reproduce exactly the figures, the architectural settings, and the stylized vegetable forms of the imported lacquers. Then, in keeping with the playful spirit of the rococo, they modified these designs by introducing European figures, exotic animals such as monkeys, draperies and arabesques, and cartouches and ribbon compositions. Along with this transformation, in place of the conventional black and gold of the Oriental products, came a wide choice of background colours, including scarlet, yellow, white, blue, and green, sometimes flecked with gold. Particularly in Venice, where craftsmen followed the rules of a treatise by Filippo Buonanni (1722), a great originality was achieved by the informal spacing of bouquets of flowers around gracefully posed figures set against delicate hues of yellow and bluish green.

The uses of lacquer in Europe reflect the changing tastes of the 17th and 18th centuries. In the late 17th century it was principally employed for decorating the cases of cabinets set upon carved Baroque bases or for ornamenting leather wall coverings. In the 18th century, bookcase desks, tall clocks, and tea tables became the most fashionable articles of lacquered furniture in England and Germany, while in France and Italy the chest of drawers and corner cabinet were preferred. Whole sets of furniture with Orientalizing lacquer decoration were made in England by Giles Grendey (Figure 192) and other cabinetmakers of the Chippendale era (1754–68), many of whose masterpieces are housed in the Victoria and Albert Museum, London. Rooms with lacquered walls have survived at the palaces of Nymphenburg outside Munich, Bamberg, and other German cities. Small lacquered boxes called *Boîte de Spa* became a specialty of that Belgian town and the nearby centres of Liège and Aachen, where a member of the Dagly family was active.

In the early 19th century the solemn grandeur of the international Classical style with its insistence on plain wood or gilt surfaces almost eliminated the taste for lacquered furnishings. It survived in Victorian times in the vogue for painted tin or toleware (as in Pontypool, England) and the decoration of small tables and chairs of papier-maché inlaid with mother-of-pearl. The making of this furniture, dominated by the London firm of Jennens and Bettridge, rapidly declined after reaching the height of its popularity about the time of the Great Exhibition held in London in 1851. In the period 1925–30, two European sculptors, the Belgian Marcel Wolfers and the Franco-Swiss Jean Dunand, successfully approximated the true Oriental lacquer techniques in a few art objects of clay, wood, and bronze. By this time, however, the making of lacquer surfaces had become a part of the chemical industry, which today produces effects of depth and hard translucence surpassing the finest products of the European lacquer masters of the past. (R.C.Sm.)

MOSAIC

Mosaic is the art of decorating a surface with designs made up of closely set, usually variously coloured, small pieces of material such as stone, mineral, glass, tile, or shell. Unlike inlay, in which the pieces to be applied are set into a surface that has been hollowed out to receive the design, mosaic pieces are applied onto a surface, which has been prepared with an adhesive. Mosaic also differs from inlay in the size of its components. Mosaic pieces are anonymous fractions of the design and rarely have the dimensions of pieces for intarsia work (fitted inlay usually of wood), whose function is often the rendering of a whole portion of a figure or pattern. Once disassembled, a mosaic cannot be reassembled on the basis of the form of its individual pieces.

Technical insight is the key to both the creation and the appreciation of mosaic, and the technical aspects of the art therefore require special emphasis in the present section, both in those portions devoted to materials and methods and in the historical survey of the major periods and centres of mosaic activity. Stylistic, religious, and cultural aspects of mosaic, its role in Western art, and its appearance in other cultures are also dealt with in order to complete the picture of an art form that appears in widely separated places and at different times in history, but only in one place—Byzantium—and at one time—4th to 14th centuries—rose to become the leading pictorial art.

Principles of design

Interaction of painting and mosaic

Between mosaic and painting, the art with which it has most in common, there has been a reciprocal influence of varying intensity. In colour and style the earliest known Greek figurative mosaics with representational motifs, which date from the end of the 5th century BC, resemble contemporary vase painting, especially in their outline drawing and use of very dark backgrounds. The mosaics of the 4th century tended to copy the style of wall paintings, as is seen in the introduction of a strip of ground below the figures, of shading, and of other manifestations of a preoccupation with pictorial space. In late Hellenistic times there evolved a type of mosaic whose colour gradations and delicate shading techniques suggest an attempt at exact reproduction of qualities typical of the art of painting.

In Roman imperial times, however, an important change occurred when mosaic gradually developed its own aesthetic laws. Still basically a medium used for floors, its new rules of composition were governed by a conception of perspective and choice of viewpoint different from those of wall decoration. Equally important was a simplification of form brought about by the demand for more expeditious production methods. In the same period, the increasing use of more strongly coloured materials also stimulated the growing autonomy of mosaic from painting. As a means of covering walls and vaults, mosaic finally realized its full potentialities for striking and suggestive distance effects, which surpass those of painting.

The general trend towards stylization—that is, reduction to two-dimensionality—in late antique Roman painting (3rd and 4th centuries AD) may have been stimulated by experimentation with colour in mosaic and particularly by the elimination of many middle tones for the sake of greater brilliance. The central role played at that time by mosaic in church decoration, for which it is particularly well suited, encourages the assumption that the roles had shifted and painting had come under its influence. The strong, sinuous outlines and the absence of shading that came to characterize painting during certain periods of Byzantine and western European art of the Middle Ages may have originated in mosaic technique and use of materials. It is notable, however, that from the Renaissance to the 20th century, mosaic was again wholly dependent on painting and its particular forms of illusionism.

In modern mosaic practice, the main tendency is to build on the unique and inimitable qualities of the medium. Although not a few of the works created in the 20th century reveal the influence of painting, figurative or abstract, the art has gone a long way towards self-realization. By and large the modern mosaic maker shares with his medieval predecessor the conviction that there are functions to which the materials of mosaic lend themselves with particular appropriateness.

Materials

In antiquity, mosaics first were made of uncut pebbles of uniform size. The Greeks, who elevated the pebble mosaic to an art of great refinement, also invented the so-called tessera technique. Tesserae (Latin for "cubes" or "dice") are pieces that have been cut to a triangular, square, or other regular shape so that they will fit closely into the grid of cubes that make up the mosaic surface. The invention of tesserae must have been motivated by a desire to obtain densely set mosaic pictures which could match, in pavements, the splendour of contemporary achievements in painting.

Invention of the tessera technique

Tesserae vary considerably in size. The finest mosaics of antiquity were made of tesserae cut from glass threads or splinters of stone; ordinary floor decorations consisted of cubes about one centimetre square. Medieval works often display a differentiation in tessera size based on function: areas requiring a wealth of details, faces and hands, for instance, are sometimes set with tesserae smaller than average, while dress and jewelery are occasionally set with very large, single pieces.

As long as mosaic was a technique for the making of floors, the main requisite of its materials, besides their colour, was their resistance to wear.

STONE

Stone, therefore, was long dominant, and throughout antiquity the natural colours of stone provided the basic range of tints at the artist's disposal; they put their mark not only on the earliest Greek works but continued to determine colour schemes far into Roman times. Stone continued to be used in Christian monumental decorations but on a more limited scale and for special effects. In Byzantine mosaics, faces, hands and feet, for example, were set with stone, while cubes of marble, often of coarse crystals, were used to depict woollen garments. Stone was also used for background details (rocks, buildings), probably to bring about particular illusions. Though marble and limestone were ordinarily preferred, in a period when Roman mosaic cultivated a black and white technique, black basalt was widely employed. Marble cubes painted red, probably to substitute for red glass, have been found in many Byzantine mosaics, in 9th-century works at Istanbul, for example.

Because its granular, nonpolished surface is often preferred to the hard brilliance of other materials, stone is also widely used in modern mosaics. At the University of Mexico in Mexico City, for example, the mosaics covering the exterior of the library by Juan O'Gorman (1951–53) and the exterior of the stadium by Diego Rivera (1957) are made with natural stone (Figure 193).

GLASS

Glass, which first appeared among the materials of mosaic in the Hellenistic period (3rd–1st century BC), brought unlimited colour possibilities to the art. In floors, however, it had to be used sparingly because of its brittleness. In floors, glass tesserae were used for the strongest hues of red, green, and blue, while softer tints were rendered with coloured stone. With the development of wall mosaic, glass largely took over the functions of stone, producing tints of unsurpassed intensity and leading to a continuing search for new coloristic effects.

With little knowledge of the laws of optics but with immense practical experience, mosaic makers of the Early Christian period gave the art a completely new direction with the exploitation of gold and silver glass tesserae. Like

Gold and silver tesserae

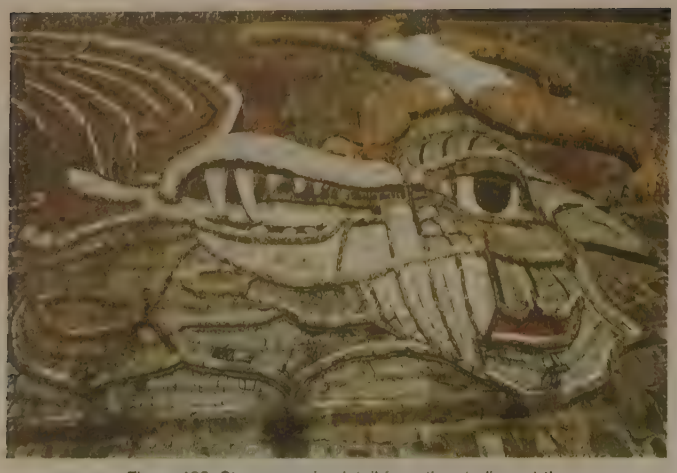

Figure 193: Stone mosaic, detail from the stadium at the University of Mexico, Mexico City; by Diego Rivera, 1957.
Harrison Forman

a mirror, the glass from which this kind of tesserae was made had a metal foil applied or, better, encased in it. The metal was gold leaf or, for the "silver," probably tin. These pieces of mirror glass gave golden or white reflections of high intensity and could be used to depict objects of precious metal or to heighten the effect of other colours; but, above all, it was used as a means of rendering the light emanating from God.

Gold tesserae were first used by the Romans, in both floor and vault decoration of late antiquity. Initially, their role was simply to give a golden effect. Gold tesserae, for example, were employed to depict a golden wreath in a floor mosaic at Antioch (*c.* AD 300) and gold vessels in some of the vault mosaics in Sta. Costanza in Rome (Figure 194). Later, when this use of gold for imitation purposes had become more refined, some spectacular effects were produced in the depiction of garments. The Good Shepherd in the Mausoleum of Galla Placidia at Ravenna (*c.* AD 450) is dressed in golden robes of densely set gold cubes shaded with stripes of light-yellow tesserae. The female saints in S. Apollinare Nuovo (*c.* AD 550–570) in the same town wear costumes set with green glass cubes among which appear both patterns and large fields of gold tesserae, producing a striking similarity to rich silk brocade. Silver was used in a similar way. Christ scenes in S. Apollinare Nuovo (AD 500–526) employ silver tesserae in the drawn sword of Peter in the betrayal, no doubt an imitation of steel. Silver tesserae are also found in the silver jug and basin in the scene of Pilate washing his hands.

Gold cubes were distributed among the ordinary tesserae to add to the shimmer of light in ornaments and background details. To avoid an uneven gleam in the surface, the mirror effect was often moderated by setting the gold tesserae in reverse, so that the visible part of the cube is the side with the thickest sheet of glass covering the gold leaf. In the now-lost mosaics of the Church of the Dormition in Nicaea, a scholar observed another exquisite effect, which he called dark gold, created by cubes from which some of the gold leaf had been chipped off, for example, in the frontal part of Mary's golden footstool (7th or 8th century AD).

An early instance of the use of gold for depicting light emanating from God is in a representation of Christ-Helios (Christ as the Sun God) in a 3rd-century mausoleum under St. Peter's at Rome. Here, a few gold tesserae are seen in the rays coming from Christ's head. The halo of gold, a feature so common in Christian art that religious pictures without it can hardly be imagined, developed in mosaic art in the 4th century AD. The gold background, signifying divine light, probably originated in Roman mosaic art, but the first preserved instances date from the advanced 4th century. The cupola mosaic of Áyios Geórgios at Thessaloníki (*c.* 400), for example, has a background of gold. In Italian mosaics of the 5th century, other types of background, such as a dark-blue ground or a more naturalistic landscape setting, were dominant. Only at the beginning of the 6th century did the gold background become the rule.

In addition to this massive predilection for gold, the Christian East began to use silver to depict the symbolic light emanating from Christ. First, it was used for the entire disc of his halo, later only for the cross arms. The archangels were the only figures besides Christ for whom the silver halo was used. The light of God, appearing as rays from above in scenes of the Annunciation, Nativity,

SCALA, New York

Figure 194: Use of gold tesserae, detail from the Early Christian vault mosaics of Sta. Costanza, Rome, *c.* 337–354 AD.

Baptism, and Transfiguration, was also depicted with silver tesserae. Finally, silver and gold were used together in Byzantine representations of the infant Jesus whose golden robes are highlighted with silver cubes (the apse and south vestibule of Hagia Sophia, Istanbul; both 9th century).

OTHER MATERIALS

In Christian mosaics, tesserae of mother-of-pearl or coarse-grained marble cut to round or oblong shapes were used to depict pearl. Though pieces of semiprecious stones were among the mosaic materials of antiquity, their use was rarely dictated by the wish for particular sumptuous effects. Reduced to common tessera size, bits of this strongly coloured material served as part of the general colour scheme of the mosaic pictures. Objects like those of the pre-Columbian American Indian cultures, in which, because of its exquisite materials, such as turquoise and garnet, mosaic attained the status of jewelry have not been found in Western art.

Among the materials that have played and continued to play a role in the production of mosaic, ceramic is the most versatile. Terra-cotta "threads" were used in Greek mosaics as contours, and tesserae of the same material were frequently used by the Byzantines for the depiction of red objects and garments. Today, glazed or unglazed ceramic is used and is one of the strongest competitors with glass and stone. Ceramic tesserae are cut from tiles or, like much modern glass mosaic material such as pressed glass, come prefabricated. Prefabricated tesserae have the advantage of a very uniform and smooth surface which harmonizes with glass, steel, and other new building materials.

Ceramic tesserae

Techniques

The most commonly used adhesive for mosaics was mortar, the function of which in the 20th century has been largely taken over by modern, tougher kinds of cements or glue. In Roman floors, two to three layers of mortar preceded the setting bed that was to carry a tesserae facing. The first layer rested on a thick foundation of stone that prevented settling of the mortar bed and the formation of cracks. For wall mosaics the preparation was equally painstaking, and in many cases an application of a waterproofing of resin or tar preceded the laying of the mortar. There then followed two layers of coarse, roughened mortar, the stability of which was often improved by large nails that had been driven into the joints of the wall before the work of laying started. A third and final layer was of fine consistency and frequently, like the mortar for floor mosaics, contained powdered marble and binding elements such as pounded brick.

As in fresco painting (technique of using water-suspended pigments in a moist plaster surface), the setting bed was applied in patches never larger than were needed for one day's work. In a frescoed surface, the breaks between the different stages of the work can easily be detected; they are harder to discover in mosaic.

Sketches and underpainting

Numerous underpaintings discovered in wall mosaics indicate that sketches, often detailed and with the main colours suggested, were executed on the setting bed to serve as guides for the disposition of the tesserae. Similar procedures are thought to have been part of the technique of floor mosaic. In church mosaics, rough preliminary sketches have been found on layers underneath the setting bed and, in a few instances, even on the brick wall itself. This kind of preparatory sketch, for which there are parallels in wall painting, suggests that the artist was trying out the overall scheme of the decoration before making a more detailed sketch on the setting bed.

Instead of laying the tesserae one by one directly onto the mortar, another method was sometimes used. In Pompeii many of the so-called *emblēmata* (central panels of floors), which were made up of smaller than average tesserae and were often of very high artistic quality, appear to have been preset on trays of stone or terra-cotta which were then embedded in the mortar of the floor. The surrounding mosaic area was then set according to the ordinary, direct method. Although the direct method was used for wall mosaics during the Middle Ages, there are signs in at least one medieval monument of a partial use of the prefabrication—or "indirect"—method: in the cupola mosaic of the church of Áyios Geórgios, Thessaloníki (*c.* 400), the heads of the saints seem to have been inserted in the mortar in one piece. The indirect method is the one most used in the 20th century. In the workshop, the mosaic is first set in reverse with glue on paper or cloth and then applied to the floor or wall. The technique permits preassembling of mosaics intended even for curved surfaces, cupolas, or apses. It has been hypothesized that behind the enormous output of floor mosaics in the Roman era lay similar production methods which had developed out of the tray procedure described above. The introduction of wall mosaics led to experimentation with the spacing and angling of tesserae. The solidity of floor mosaics depended on a close-set texture, but in wall mosaics, in which the element of wear was no longer relevant, the organization of the surface could become looser. For several centuries, a very wide spacing of the tesserae was cultivated, and the placing of cubes at irregular angles was regarded as important to the over-all effect of wall mosaics. These tendencies reached the extreme in the 7th and 8th centuries, in mosaics of the chapel of S. Venanzio in the Lateran Baptistery, Rome (Figure 195), and in the fragments of the

SCALA—Art Resource

Figure 195: Wide-spaced tesserae set at irregular angles in the head of a saint, detail from mosaics in the Chapel of S. Venanzio, Lateran Baptistery, Rome, *c.* 640 AD.

decoration of Pope John VII (AD 705–707) in the old St. Peter's in the Vatican. Later periods preferred a somewhat closer setting, but the irregular surface continued to be in fashion for most of the Middle Ages.

Tilting of tesserae

The tilting of tesserae became an art in itself. In 6th-century Byzantine mosaics, there evolved a new technique whereby gold and silver tesserae were set at extremely sharp angles to enhance reflection. By pointing their mirror ends downward in the direction of the onlooker it was possible to secure maximum light effect. In Hagia Sophia at Istanbul, the enormous gold areas in the wall mosaics of the emperor Justinian are set with cubes tilted this way. In one particularly dark corner, the tesserae are not only tilted downward but are also turned slightly sideways to catch the light from a nearby window. A similar technique, based on a high degree of tilting of the gold tesserae in unlit areas, can be observed in the mosaics of the Dome of the Rock in Jerusalem (*c.* AD 690).

Haloes set with tilted cubes that bring out the circle of light surrounding the heads of holy figures became common in Byzantine mosaics of the 6th to 7th centuries,

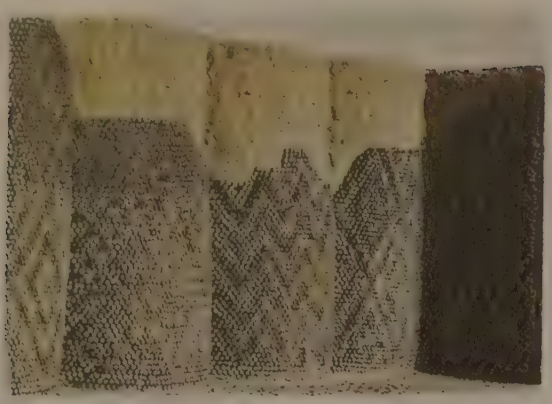

Figure 196: Columns decorated by the Sumerians in a mosaic-like technique with polychrome terra-cotta cones, from Uruk, Mesopotamia, early 3rd millennium BC. In the Staatliche Museen zu Berlin.
By courtesy of the Staatliche Museen zu Berlin

as is seen in the mosaic panels dating from this period in the church of Áyios Dhimítrios, Thessaloníki. Striking examples of such haloes are also found among mosaics that were put up in Hagia Sophia in Istanbul in the 9th century, above all in a panel with the kneeling emperor (Leo VI?).

Effects such as those described above are unthinkable without the accumulated experience of the craftsman-artist. In the 20th century, mosaic increasingly has become an art divided between the inventor who furnishes the design and the worker who executes it. It may be that the dry character of many modern mosaics can be ascribed to the fact that the artist no longer puts his thumb on every tessera.

Periods and centres of activity

Among the cultures of the ancient Near East there is one remarkable occurrence of a mosaic-like technique: the exteriors of some large architectural structures, dating from the 3rd millennium BC, at Uruk (Erech) in Mesopotamia, are decorated with long terra-cotta cones imbedded in the wall surface (Figure 196). The blunt, outer ends of the cones, coloured in red, black, and white, form patterns consisting of zigzag lines, lozenges, and other geometrical motifs. This revetment was decorative as well as functional, for the cones shielded the core of sun-dried bricks from rain and wind. The technique, however, died out and seems to have had no influence on the later development of mosaic.

Terra-cotta cone mosaics

In western Asia Minor are preserved the earliest examples of the surface-covering technique that lead to mosaic in the present sense of the word. In the town of Gordium near modern Ankara in Turkey, houses have been uncovered with floors made of pebbles set in a primitive mortar. In some of these floors (dated to the 8th century BC), rows of light pebbles form awkward geometrical figures against a background of darker stones. These rudimentary elements of decoration introduced into a crude form of pavement laying spurred artistic imagination and set in motion a process that was to bring spectacular results.

ANCIENT GREEK AND HELLENISTIC MOSAICS

Three main phases can be determined in the development of mosaic art in antiquity. The first, chiefly a Greek matter, involved the gradual perfecting of the pebble medium. The second, which saw the invention and spreading of the tessera technique, took place partly in the Hellenistic Greek world and partly on Roman soil. The third, largely a Roman phenomenon, was characterized by the popularization of mosaic and the application of the medium to new functions. By a process of diffusion, the taste in floor decoration documented at Gordion spread through the Greek-speaking world of the Mediterranean. Its first full flourishing seems to have occurred in late Classical times. Pebble mosaics are found as far west as Sicily (Motya, Morgantina) and, in the east, in the Greek colonies on the Crimea (Cherson). They are preserved in large number at only two sites, Olinthos and Pella, in Macedonian northern Greece.

In the town of Olinthos there are floor mosaics, with elaborate figures and complicated patterns, which were part of the new city culture that developed in the 5th century BC. The Olinthos mosaics also reveal that picture making with light and dark pebbles had by then evolved into an intricate art. Against a ground set with black or blue-black stones stand figures or patterns set with white or slightly tinted ones. Pebble size had become fairly uniform, with diameters from one to two centimetres, but particularly intricate areas, like faces, are set with smaller stones. Very small black pebbles serve as outlines. Although the mortar between them is visible, the pebbles are set close enough so that the pictures appear with regular, not too broken outlines and with some emphasis on detail.

Floors in houses at Pella, dating from the 4th century BC, demonstrate a significant later development of the pebble technique (Figure 197). Floor mosaics then openly vied with wall painting in the rendering of space and realistic detail. This was made possible by the introduction of new materials that eliminated the shortcomings of the ordinary pebble medium. Among the basic changes was an increase in the range of colours. When the demand for particular tints could not be met with pebbles of natural colours, "artificial pebbles" were made and are found in several of

Figure 197: Greek pebble mosaic, detail from The Lion Hunt, from Pella, Macedonia, *c.* 300 BC.

the floors at Pella. These "pebbles" have been painted in the required tones—mostly strong green and red—and, to protect the film of paint, have a depression sunk in the middle. The new trend also called for smaller pebbles to permit pictures to be set more closely. To obtain precise delineation of limbs and features, outlines made not with pebbles but with long strips of terra-cotta or lead wire were employed. Pictures made in this technique reflect a taste for heroic hunt scenes and fights with wild animals, themes inspired from court art glorifying the ruler.

The next innovation came at the end of the 4th or the beginning of the 3rd century BC, when the introduction of new principles led to the abandonment of the pebble technique. Cut mosaic pieces permitted the nearly complete elimination of the disturbing effects of visible mortar patches, and new materials, above all glass, offered a vast new range of colours. The acceptance of the new methods

and materials seems, however, to have come about slowly. In Alexandria (Greco-Roman Museum) there is a mosaic (depicting Erotes fighting a stag and, in the outer border, a frieze of animals) in which cut, triangular tesserae are used together with both pebbles and lead wire. In somewhat later Alexandrian mosaics made with tesserae (late 3rd/early 2nd century BC) lead threads are still in use; for example, in a panel signed by the artist Sophilos and depicting a personification of Alexandria, that is the earliest known example of miniature mosaic work (called *opus vermiculatum*, meaning "wormlike work" because of the close-set, undulating rows of small tesserae).

The Pergamum School

Pergamum, another centre of the Hellenistic world, was particularly famous for its school of mosaics. According to the ancient Roman historian Pliny the Younger, Sosos, one of the most renowned mosaic artists of antiquity, worked in this city. None of his works survives but, thanks to Roman copies, the intentions that underlay his art can be judged. Pliny listed as his most celebrated works a representation of drinking doves and a clever imitation of the "unswept floor" of a banquet room (*asarōtos oikos*). The copies tell of Sosos' phenomenal ability to create trompe l'oeil ("fool-the-eye") effects through a shading and colouring that seems to bring the objects out in full plasticity on the ground on which they are depicted. To call the work merely an imitation of painting may be incorrect. The intense colours and the smooth texture permitted by the new setting technique paved the way for illusionistic effects that went beyond those achieved by painting.

ROMAN MOSAICS

Eager to adopt the artistic culture of the Hellenized eastern Mediterranean, the Romans introduced mosaic in this exquisite form in both their domestic architecture and their places of worship. Pompeii has yielded a host of *opus vermiculatum* works datable to the 2nd/1st century BC. Among these the most famous is the Battle of Issus, found in the Casa del Fauno in 1831 (Figure 198). This is the largest of all known works, measuring about 11.22 by 19.42 feet (3.42 by 5.92 metres), in the miniature mosaic technique. This mosaic (which probably copies a work of painting, perhaps a famous picture by Philoxenus of Eretria) and other Pompeiian panels of similar quality are supposed to have been executed by Greek artists, who carried on in the tradition established at Alexandria and Pergamum.

SCALA—Art Resource

Figure 198: "Battle of Alexander and Darius at Issus," detail of the Roman mosaic done in the *opus vermiculatum* technique, from the Casa del Fauno, Pompeii, late 2nd century BC. In the Museo Archeologico Nazionale, Naples.

The Romans transformed mosaic from an exclusive art to a common decorative medium. Some of the earliest examples of this new type of floor are in the late republican (2nd century BC) houses at Delos. For rooms of secondary importance and often for floors surrounding the finely designed and executed central *emblēmata* (a featured picture or ornamental motif) in the most important rooms, the Romans developed a simpler, less artistic kind of mosaic. The floors are set with fairly large tesserae with a limited range of colours, some tending toward monochrome (black-and-white). The decorative designs and motifs are also simple and uncomplicated.

SCALA—Art Resource

Figure 199: Roman monochrome floor mosaic in the Portico delle Corporazioni, Ostia, Italy, 3rd century AD.

Roman floor mosaics

This new trend in mosaic floors was probably stimulated by new and functional ways of thinking about the role of floors in architecture. To the practical Romans it may have seemed illogical that floors destined for rough wear should bear delicate pictures. Moreover, the demand for large-scale mosaic making brought about by the colossal urban expansion in the 1st century AD made the development of quicker and simpler techniques imperative. The aim of the Romans seems to have been to create a style, technique, and form of composition that would be simple and functional. Competition with painting in illusionistic and coloristic refinement was therefore abandoned; *emblēmata* gave way to decorative elements distributed over the floor in one large overall pattern or to figure compositions taking the full floor plane; and polychrome gave way to monochrome mosaics (which may have been easier to produce). Enormous floors in the baths and in the courtyards of warehouses (1st to 3rd century AD) at Ostia, Rome's port at the mouth of the Tiber, are the best preserved examples of the monochrome style (Figure 199).

The expressionist Roman style, which flourished in Italy, penetrated into the former Greek cities in the eastern part of the empire, but polychromy and types of composition based on the framed picture persisted with especial tenacity due to strong local Hellenistic traditions. A splendid series of *emblēmata* (2nd century) with mythological representations, allegories, and scenes from the theatre have been uncovered at Antioch in southern Turkey. They prove the existence of a school there of mosaicists of particular brilliance. Recent research has pointed to the African provinces as the site of another, highly active school with a taste for larger, dramatic compositions. Influence from these areas may have been responsible for the renewed opulence, represented by a vivid polychrome pictorial mosaic, which reappeared in Roman art in late antiquity. Outstanding examples of this renewal are the mosaics in the Roman villa of Casale (*c.* AD 300) near Piazza Armerina, Sicily. The mosaic decoration of this vast palace complex culminates in the gallery of the Large Hunt, which contains a scene of animal hunting

and fighting covering an area of 3,200 square feet (300 square metres).

It is generally agreed that in the course of the 3rd century the status of mosaic was radically altered. Already in Hellenistic times the medium had been employed for other ends than floor covering and had become part of the embellishment of the fantastic garden architecture of which the rulers of the period seem to have been particularly fond. Reflections of this tradition in the 1st century AD are the mosaic-covered fountains in the mansions at Pompeii and Herculaneum and mosaic panels and niches in rustic banquet halls and artificial grottoes at The Golden House of Nero in Rome and his villa at Anzio. Mosaic fragments and imprints of tesserae in the vaults of baths and buildings of similar size demonstrate that mosaic gradually was introduced into new fields. Equally important is the evidence that mosaic was used to depict sacred images. On some of the monochrome floors at Ostia are scenes pertaining to animal sacrifice and to the cult of the dead. Three monuments of the 3rd century inform of another new practice introduced at this time, that of putting mosaic pictures of religious importance on walls: a niche mosaic with the god Silvanus from a temple of Mithra at Ostia; a Christian wall and vault mosaic depicting Christ as Helios, the Sun God, in a mausoleum under St. Peter's, Rome; and a decoration, now lost but recorded in a 17th-century drawing, of a chapel for the Lupercalian worship at Rome. It has been pointed out by modern scholarship that the new role gradually assumed by mosaic must be related to the corresponding decline in interest in three-dimensional representation. The cultic mosaic took over the function of the cult statue, mosaic being that two-dimensional medium which was considered most capable of convincingly expressing religious ideas in visual form.

Cultic mosaics

EARLY CHRISTIAN MOSAICS

Present-day insight into the crucial, early phase of this part of the history of mosaic is limited because of the loss of nearly everything that was made in the field during the first half of the 4th century. Nevertheless, as indicated above, it seems certain that wall mosaics had come into use in Roman art well before Emperor Constantine's edict of toleration of the Christian faith in AD 313. Considered to be among the earliest Christian wall mosaics in Rome are those in the church of Sta. Costanza built about AD 320–330 as a mausoleum for Constantine's daughter. The content of the pictures is almost completely Dionysiac and pagan, but a series of small format scenes from the Old and New Testaments were included among the non-Christian pictorial elements of the decoration. Obviously an independent Christian pictorial program for buildings of Sta. Costanza's size and complexity had not yet been developed; and, probably in lieu of that, a Dionysiac program had been chosen because its many allusions to the symbolism of wine lent themselves to a Christian interpretation.

Other monuments of the 4th century bear similar marks of transition. Floor mosaics in the cathedral complex at Aquileia demonstrate that the church before and immediately after Constantine's edict of tolerance of the Christian faith in AD 313 adhered to the late antique tradition of placing religious pictures in pavements. In the earliest group of Aquileia mosaics (*c.* AD 300) objects and animals symbolize the Good Shepherd, while the later group (second decade of 4th century) contains scenes from the story of Jonah, symbolic animals, such as the deer and the lamb, and a representation of the bread and the wine. Before long, pictures of this character were banished from floors, and simpler and more general symbols took their place.

The latest of the preserved transitional works, a decorated cupola in a mausoleum, possibly imperial, at Centcelles (now Constantí, Tarragona), Spain, seems to have been made not long after AD 350. This very fragmentary decoration has yielded important information about a stage of increasing mastery in the handling of the medium. The scenes from the Old and the New Testament are presented with greater self-confidence and occupy a full, broad zone in the lower part of the cupola. Yet, below it is a stag hunt, rich in symbolic content but adhering closely to the patterns of profane floor mosaics. Stone tesserae dominate in the lower zones, but glass cubes are found in large quantities in the upper. Glass, with its stronger colours, was doubtlessly concentrated in this area intentionally. The zenith of the cupola, weak in lighting and distant from the spectator, needed tesserae of strong reflecting power to make it possible to read its decoration.

A series of large, in part well-preserved mosaics make it possible to follow the progress of the art in 5th-century Italy. Ravenna and Rome have several important works, while Naples and Milan have preserved enough to suggest that workshops of high artistic standard must have existed in many of the large cities of the peninsula. In these works, the tendency to clarify and even underline the content of religious pictures with the help of colour is brought to its full peak. The swing towards a greater employment of glass reached a point at which the mosaics are almost entirely made of this material. In what must be regarded as a late but vigorous revival of the painterly illusionism of antiquity, there is an audacious blending of colours. Among the high points of this trend are the flaming visages of angels in Sta. Maria Maggiore, Rome (*c.* AD 432–440) and the spiritualized physiognomies of St. Bartholomew and his fellow apostles in the Baptistery of the Orthodox, Ravenna (*c.* 450). But the designer's mastery and sophistication are nowhere more overwhelmingly illustrated than in the glowing interior of the so-called Mausoleum of Galla Placidia (*c.* 450) at Ravenna, with its blue star-filled mosaic dome, and in the decoration of the Naples Baptistery of S. Giovanni in Fonte (5th century), with its hypnotizing glimmer.

A Christian language of pictures (iconography) was now developed, and its grammar worked out. In cupolas, the centre tended to be reserved for depictions of Christ or the cross. In apses there was a trend toward static and symbolical representation of holy figures and a reduction of detail. On the walls of the nave of basilicas were scenes from the Old or the New Testament or both. The largely intact decoration of the church of Sta. Maria Maggiore, Rome, throws some light on the principles involved.

Development of an iconographic tradition

Old Testament scenes are distributed on the side walls of the nave in panels measuring about six by six feet (1.9 by 1.9 metres). There is one panel below each of the basilica's large windows. The pilasters (columns projecting shallowly from the surface of the wall) between the windows (restored but repeating the original disposition) serve as outer frames for these panels. Before the restoration of the church in the 16th century there were also inner frames, made of stucco; in addition, each panel was adorned with a small pediment (triangular gable) of the same material and thus appeared as if enshrined by a small aedicula (a pedimented niche). The classical rules governing the relation between the architecture of a building and its decoration may be expected to leave their mark on Christian mosaic art for a long time.

BYZANTINE MOSAICS

Early Byzantine mosaics. Mosaics made in Ravenna for the Ostrogoth king Theodoric (AD 493–526) are the first full manifestations of Byzantine art in the West. As seen in two of the foremost works from his time, the Baptistery of the Arians and the church of S. Apollinare Nuovo, the gold background now dominates. Accompanying it was silver, a novelty among the mosaics of Italy. In S. Apollinare Nuovo, the faces and hands in several of the Christ scenes are set not with glass tesserae but with cubes of stone. Stylistically, these mosaics are characterized by more static figures and less depth and plasticity than in those of the 5th century.

Another remarkable element is the movement, now fully developed, toward an integration of architecture and mosaic decoration. This is most clearly seen in the basilica. In the church of S. Apollinare Nuovo, the mosaics are no longer inserted panels but form a continuous "skin" that covers every inch of the wall. The size of the windows and even their number have been reduced, apparently to provide more wall space for pictures. Figures have grown in size, to match the dimensions of architectural components, and they seem to have taken the place of pilasters

Developed integration of architecture and mosaic decoration

in the articulation of the room. This trend is given truly monumental expression in the choir of the church of S. Vitale at Ravenna, dating from *c.* AD 526–548. A profusion of decorative elements is spread like tapestry over the walls and vault, the panels of the emperor Justinian and his consort Theodora near the apse embodying the new spirit in their colour-laden pageantry.

In the East, the circular church of Âyios Geórgios at Thessaloníki, Greece, shows Byzantine mosaic at its earliest flourishing (*c.* AD 400). Its partly preserved mosaics display a disposition related to that of the Baptistery of the Orthodox at Ravenna, with a lower zone containing Paradisiac architecture; above this a zone with standing and walking figures and in the centre of the cupola a medallion with a figure of Christ. A uniform gold background dominates the two lower zones, at a time well before it had come into general use in the West. Silver is found in profusion, used for the background in the central medallion as well as a means to enhance the radiation of light from all parts of the mosaic. In the figures of saints the material for faces and hands is chiefly natural stone, its gentle gradations contrasting spectacularly with the violent juxtapositions of coloured glass tesserae of the hair and the garments.

Effects of this kind, which are the hallmark of Byzantine mosaic technique, seem to derive from intentions wholly dissimilar to those which had determined the development of early Christian mosaic art in the West, where the illusionism of Greco-Roman art persisted for a long time. In the great Ravenna mosaics of the 5th century, pictures illustrating the narrative of the Bible or expounding the dogmas of religion were still done in the painterly style of Roman mosaics and wall painting. During the same period, mosaic art of the Eastern Empire, having abandoned conventional illustration, was boldly exploring the way that lay open, in mosaic art, toward a new kind of imagery.

In the mosaics of the 6th century are found the earliest refinement introduced by the Byzantines to enhance the brilliance of gold tesserae. This refinement, already described, involved setting gold cubes at oblique angles to direct their reflections toward the viewer. Used in haloes, the tesserae, obliquely set, convey to the holy figures a miraculous aura of light. The visages of the saints, with their dull stone surfaces and hues reminiscent of actual human skin, add a touch of mysterious reality to this theatre of effects.

Rene Percheron—J.P. Ziolo

Figure 200: Gold tesserae reflecting light to the viewer; from the Byzantine votive mosaic showing St. Demetrios between two donors, from Âyios Dhimítrios, Thessaloníki, Greece, 7th century.

Splendid mosaics from many parts of the eastern Mediterranean testify to the continuous cultivation and improvement of these effects. In the city of Thessaloníki the mosaics in the churches of Hosios David (5th century AD) and Âyios Dhimítrios (6th and 7th centuries) exemplify the trend (Figure 200), which is also expressed in apse decorations preserved at Cyprus (church of the Panagia Angeloktistós, at Kiti, and of the Panayía Kanakaria near Lythrangome; both 6th century) and in the Monastery of St. Catherine, Sinai Desert, founded by Justinian.

Apart from the gold ground, which had considerable impact, the technical subtleties essential to these mosaics met very little response outside Byzantium. When Byzantine artisans operated in foreign territory, they brought their particular techniques with them. Again and again the impact of this tradition was felt in the West, though, at its purest, mostly as short-lived episodes. To judge from a few surviving fragments, mosaics executed under Pope John VII (AD 705–707) in a chapel in St. Peter's, Rome, might have been the work of artisans summoned from Byzantium. Technical and stylistical features demonstrate that the mosaics executed under the earliest Muslim rulers, in the Dome of the Rock at Jerusalem (*c.* AD 690) and in the Great Mosque at Damascus (*c.* AD 715), are certainly the work of specialists called from Byzantium. Sources testify that even the mosaics in the mosque at Córdoba, Spain (AD 965), were made by Greek craftsmen.

The floor mosaics in the great palace of the Byzantine emperors at Istanbul—with their pastoral scenes, fights with wild animals, and figure groups taken from pagan mythology—testify to an undercurrent of classical taste in Constantinople. The date, which according to archaeological evidence must be placed as late as around the year AD 600, demonstrates the tenacity of that taste in the midst of the Christian milieu of the Byzantine metropolis.

Middle Byzantine mosaics. Scholars have been concerned to discover how Iconoclasm, the dispute concerning images during the 8th and 9th centuries, may have influenced the course of Byzantine art. In some respects, at least, mosaic reflects very little change. The main source of knowledge about the state of mosaic in the time shortly after the end of Iconoclasm is Hagia Sophia at Istanbul. Parts of the redecoration that the church underwent in the last half of the 9th century have been uncovered in recent times. In their colour and technique these show a continuation of the early Byzantine tradition: the preference for rather strong, clear tints, and the effects created by such techniques as the tilting of tesserae and the turning of gold cubes. The preoccupation with light seems stronger than ever: in badly lit places in the vestibule and gallery, the gold ground displays a high percentage of silver cubes among the gold ones to add to the sparkle. Stylistically, new ground had been broken. Particularly in faces, the tesserae are set in wavy lines which break up the modelling in bandlike configurations. Linearism (the expression of form in terms of line rather than colour and tone) had taken a great step forward.

Mosaics of Hagia Sophia

In the arrangement and distribution of pictures new features are visible. In the apse of Hagia Sophia, the Virgin with the Child sits surrounded by a vast expanse of gold. She is one of the first of a family of similar majestic madonnas, the most striking of which is in the Cathedral of Torcello near Venice (12th century). The tendency to depict icon-like, motionless mosaic figures isolated on a gold background has pre-Iconoclastic precedents, but from the 9th century onward it became a leading decorative principle.

Nineteenth-century drawings show that the decoration of Hagia Sophia also included comprehensive series of saints. Of these saints, which stood in rows on the nave walls above the galleries, only a few have survived. According to the drawings, those of the middle zone represented prophets, those of the lower, holy bishops. Higher up there

may have been a guard of angels and in the centre of the cupola, probably a mosaic of Christ. The disposition of the pictures, in other words, may have corresponded to that which at this time was being tried out especially for the new church architecture and which was to become the accepted system of decoration in the middle Byzantine churches.

Interplay of architecture and mosaic at Daphni

The monastery church at Daphni, near Athens, contains one of the best preserved decorations of this type (Figure 201). The building belongs to a category of central-plan

Rene Percheron—J P Ziolo

Figure 201: Interplay between architecture and mosaics in the monastery church at Daphni, Greece, 11th century, crowned with a Byzantine dome mosaic Christ Pantokrator.

structures that had come into fashion and was to dominate for centuries both in Byzantium and in other areas under the influence of the Orthodox Church. The interior of the church at Daphni displays a layout which, compared with the wealth of detail of the early Christian period, appears single-minded and concentrated. In the centre of the dome is a medallion containing a colossal bust of Christ as Pantokrator, the All-Ruler. In the lowest part of the dome, separated from the medallion by a broad zone of gold, stand prophets with their scrolls. Further down, there may originally have been medallions with portraits of the Evangelists. In the four arches that carry the drum of the cupola are scenes from the life of Christ which, with eight more Christological scenes in the transepts, formed a cycle devoted to the central feasts of the church. The Virgin is represented in the apse, her guard of archangels on the side walls of the sanctuary. About thirty saints, depicted either as busts or as fulllength figures, fill the remaining wall space. In the vestibules are more scenes from the life of Christ and the remains of a cycle devoted to the life of the Virgin. Golden frames with floral ornaments surround the panels, and gold once covered every inch of wall between them.

The ensemble represents a visualization of the Christian cosmos, its effect created by an intricately conceived interplay of pictures and architecture. The worshipper who moves within this golden shell finds its world of pictures thoroughly involved with space. Space in fact fuses the decoration into one giant image, in which the ruler, hailed by the prophets surrounding him, presides in his sphere above the host of saints that people the lower part of the room.

Subtle spatial devices animate the individual pictures; figures of saints, their two-dimensionality emphasized by their outlines, appear in niches sunk in the wall or lean forward in the interior curves of arches. The 20th-century Austrian scholar Otto Demus, in studies on the aesthetics of middle Byzantine mosaic art, has coined the term space icons for this kind of imagery, in which the forms of architecture collaborate to make the solemnly stylized figures appear with unexpected tactility. As shown by Demus, the spatial element contributes to the narrative scenes also. In the four arches, for example, the hollow plane on which the scenes from the life of Christ unfold adds a dimension of spatial realism to the total image. This is most clearly to be observed in the Annunciation scene, where Mary and the Angel face each other across a stretch of real space. The figures share or are made to appear to share the room with the beholder.

The "classical system"

The "classical system," as this close interrelation of architecture and mosaic has been called, was probably perfected in the course of the 9th to 10th centuries, but the earliest fully preserved examples are from the 11th to 12th. Besides Daphni, Greece owns two more monuments of this kind, the monastery church of Hosios Loukas in Phocis and the Nea Moni on Chios (both 11th century). Similar churches are found in such widely distant places as Kiev (Hagia Sophia, 11th century) and Palermo (Martorana, *c.* 1150), both the products of strong Byzantine influence. The system, however, is not identical in any of these. The churches belong to the same general type, but their plans and elevations vary and thus require variations in this disposition of pictures as well.

The classical system with its emphasis on totality may have led to the gradual toning down of the many splendid effects of the earlier tradition for the sake of the equilibrium and clarity of the whole. At Daphni, for example, the rich, tapestry-like character of earlier mosaic has given way to a controlled, less sparkling range of tints. The reds and yellows are restricted, their function in the overall scheme taken over by the gold of the background. Sombre, often hard blues, greens, and violets are preferred to the lighter ones. Compared with the Hosios Loukas and the Nea Moni mosaics, which retain more of the older colour scheme (the latter almost to the point of brutality), the Daphni mosaics appear cool and intellectual, an impression further conveyed by their elegant style. Actually they belong to a new phase of Byzantine art which took its name from the dynasty of the Comnenus (AD 1081–1185). This style appears at its most refined in Hagia Sophia, Istanbul, in a panel depicting the Virgin flanked by the emperor John Comnenus II and his wife Irene. The practice of tilting the gold tesserae also seems to have been abandoned, for it is not found at Daphni nor in any of the mosaics that are examples of the fully developed classical system. Silver was reduced to the single role of depicting the light emanating from God and Christ. This drying out of the effects of light and colour was partly compensated for by a perfectionist setting and spacing of the tesserae.

Late Byzantine mosaics. The phenomenon called the Palaeologian Renaissance (from the dynasty of the Palaeologians, 1261–1453) led to a renewal of Byzantine mosaic art. The stylistic innovations that made themselves felt both in painting and mosaics of the late 13th and beginning 14th century bear witness to one of the most startling changes that ever took place within the framework of Byzantine culture. Bred by a vital humanism, which penetrated westward and laid the foundations for the Italian Renaissance, painting showed a predilection for perspective and three-dimensionalism. A peculiar vivacity invaded religious art, together with a sense of pathos and of the tragic. The results, as expressed in mosaics, were extraordinary.

To respond to the new trend, mosaicists recast their technique. The tessera size generally became smaller than it had been in earlier epochs; and contours lost their rigidity, became thinner, and were occasionally abolished. Colour was reintroduced in a manner that gives the Palaeologian works a striking likeness to the mosaics of the Early

Figure 202: (Left) Greek Festival Cycle miniature mosaic, 14th century. In the Museo dell'Opera del Duomo, Florence, Italy. (Right) Christ, detail from the Late Byzantine Deësis mosaic, south gallery, Hagia Sophia, Istanbul, *c.* 1300.
(Left) SCALA—Art Resource (right) Erich Lessing—Magnum

Christian period, which, one must suppose, in many cases served the artists as models. An interest in the optical effects of gold apparently returned but rarely, it seems, in the form of the tilting technique. On flat walls, the gold ground was sometimes set in a shell pattern, probably to enhance the play of light on the surface and to avoid a too-uniform brilliance. For domes, a densely ribbed form of cupola construction, which, when covered with mosaics, produces reflections of light that expand like rays from the central medallion toward the figures surrounding it, was preferred. Such domes are preserved in Kariye Cami, the former church of the Chora, at Istanbul, which was reconstructed and decorated as an act of piety by the logothete, or controller, Theodore Metochites in the second decade of the 14th century. Another superb example is found in Fetiye Cami (Church of the Virgin Pammakaristos) in the same city.

The feeling for colour, which is at its most refined in fragments from the decoration of the Church of the Holy Apostles in Thessaloníki (*c.* 1315) and at its most intense in the partly well-preserved cycles in the Kariye Cami, informs one of the greatest mosaic works of art, the Deësis panel in the south gallery of Hagia Sophia in Istanbul (Figure 202, right). In this same panel, the tilting technique reappears (in the cross arms of Christ's halo)—another indication of the retrospection inherent in late Byzantine art.

No mosaic in the true Palaeologian style has survived outside Byzantium. Reflections of it are found, however, in some of the 13th- and 14th-century works at Venice and in the mosaics executed by Pietro Cavallini in the apse of Sta. Maria in Trastevere in Rome (*c.* 1290–1300). Some of the characteristics of the style may have been brought to the attention of the Italian artists through portable mosaics, which despite their small size (generally about two by four to eight by ten inches [five by ten to 20 by 25 centimetres]) are imbued with many of the coloristic and technical features typical of monumental mosaics. Byzantine mosaic icons, the production of which was stimulated during the early Palaeologian era, were manufactured for personal devotion more than for the embellishment of churches and were exported in considerable numbers to the West or found their way there as gifts or booty in the politically troubled 14th and 15th centuries. In works whose quality can be compared with the most splendid of the Hellenistic *emblēmata*, extremely small tesserae, some measuring less than 0.04 inch (one millimetre) square, were assembled in wax or mastic on a board of fine wood. The tesserae material is often exquisite: silver, gold, and lapis lazuli and other semiprecious stones. The icons depict single figures such as saints, Christ, or the Virgin; single Christian scenes such as the Annunciation (Victoria and Albert Museum, London) and the Crucifixion (Staatliche Museen zu Berlin); or even the full Greek Festival Cycle (Figure 202, left).

Portable mosaics

MEDIEVAL MOSAICS IN WESTERN EUROPE

The prestige, both cultural and political, enjoyed by Byzantium in the Middles Ages led to a widespread imitation of its arts. Art objects in great number were imported to the West from Constantinople and other Greek centres. Individuals or communities outside the realm of Byzantium, however, were able to secure Byzantine artisans for the execution of monumental mosaics. Abbot Desiderius of the abbey of Montecassino in Italy, for example, called specialists in many crafts from Constantinople to decorate his new basilica (dedicated AD 1071). Among these were mosaic workers. Of particular importance is the fact that he took care to see that young local artists were trained by the foreigners. This was the pattern that was followed where Byzantine experts were temporarily called in.

Sicilo-Byzantine mosaics

The Norman rulers of Sicily, who vied with the Byzantines for control of the Mediterranean, molded their representational arts largely on those of the great Eastern power. The existence, at Palermo, of a central-plan church (Martorana) embellished according to the classical system has already been noted. In other 12th-century churches in Sicily, the Byzantine element is blended with western Mediterranean traits. Cappella Palatina, the palace chapel of the royal residence at Palermo (*c.* 1143 and later), for example, is a synthesis of a centralized middle Byzantine church and a basilica. The building therefore called for a hybrid program. According to Western custom, the mosaics of the basilical parts depict narrative cycles: scenes

from the Old Testament and from the lives of SS. Peter and Paul. In the centralized part of the church most of the features belonging to the classical system are at hand. There is a bust of the Pantokrator in the dome, surrounded by angels, but as a concession to the longitudinal disposition of the church, the Pantokrator reappears in the apse.

Martorana and Cappella Palatina were decorated by Byzantine artists, a fact borne out by the brilliant technique, the purity of the Comnenian style, and the adherence to Eastern iconographical prototypes. Two large basilicas are among the highpoints of this Sicilo-Byzantine flowering: the cathedral of Cefalù (*c.* 1148) and the church of Monreale, the last of the mosaic churches of Sicily (*c.* 1180–90). Demus has pointed out the extraordinary homogeneity of style and technique in the Monreale mosaics, which constitute the largest decoration of this kind in Italy. He has also shown that the Monreale mosaics are not executed in the refined and softly curved style that dominates in Cappella Palatina and at Cefalù. Monreale is infused with a more agitated and expressive style which, however, has nothing local or provincial about it. It was the late Comnenian style of Constantinople which had then reached Sicily—a testimony to the unbroken artistic contact that existed at this time between the Norman court and Byzantium.

Italo-Byzantine mosaics in Venice

Venice, for a long time commercially active in the eastern Mediterranean, enjoyed similar but more long-lasting artistic connections with Constantinople. A church that in the 11th century must have looked exotic as well as old-fashioned, St. Mark's was copied after the venerable Church of the Holy Apostles at Constantinople, an early Byzantine, many-domed type that had long since gone out of favour.

The mosaic work undertaken at St. Mark's lasted more than two centuries, from the end of the 11th to the middle of the 14th century. The many and marked stylistic disparities can be ascribed in part to the changes that affected Byzantine art during this period; but they may even have been caused by the freer, Western organization of the Venetian workshop, which allowed artists to develop and cultivate their own personal styles. Among the variety of styles, the Byzantine element is dominant, but it is modified by local tendencies and particularly by strong Romanesque impulses.

The workshops established in Sicily and Venice were active in the neighbouring areas. Mosaics in the cathedral at Salerno (*c.* 1190) and in the monastery at Grottaferrata near Rome (*c.* 1200) are regarded as products of the Sicilo-Byzantine school. The apse decoration of the cathedral at Ravenna (early 12th century), of which fragments survive, seems to have been the work of mosaicists from Venice and, in Florence, Venetian artists decorated the dome of the Baptistery (1225–1330). The much later mosaics on the facade of the cathedral at Prague (14th century) are also Venetian.

The Roman school

In the early Middle Ages, Rome had been able to maintain and defend a mosaic tradition of its own despite the Byzantine hegemony in the arts. At a period when Iconoclasm had loosened the ties between Byzantium and the West, at the end of the 8th century and the beginning of the 9th, the influence of the Roman school extended even into the Carolingian Empire. The apse mosaic of Germigny-des-Prés, France (between 799 and 818), is a product of this influence. In Rome, the pontificate of Paschal I (817–824) left three monumental decorations which constitute the best sources concerning the artistic intentions of this time: the sanctuary mosaics of the churches of Sta. Cecilia in Trastevere, Sta. Maria in Domnica, and Sta. Prassede (attached to the latter is the domed chapel of S. Zeno, also fully decorated with mosaics). The iconographic schemes of these 9th-century churches largely reflect local 5th- and 6th-century church decorations. Also remarkable is the return of many of the technical idiosyncrasies of the early Christian period, including the employment of large tesserae for faces and dress and the use of glass for all parts of the composition. The setting of the tesserae is, however, loose and disorganized; and their varying shapes suggest that they are reused cubes taken from older monuments. Stylistically, the mosaics of the Paschal period, with their extreme two-dimensionality, are related to Byzantine mosaics of the 9th century (the cupola of Hagia Sophia, Thessaloníki), but technically the differences could not be greater.

Little is known of the art in 10th and 11th century Rome. But from the 12th century, a group of works testify to continued inbreeding. The apse decoration of S. Clemente (the 1st half of the 12th century), for example, contains a scroll pattern (rinceaux) reproduced from a 4th-century decoration in a technique that in many respects resembles that of the Paschal mosaics. This isolation, or resistance to foreign influence, seems to have been broken in the 13th century. In 1218, Pope Honorius III asked the doge to send craftsmen for the decoration of S. Paolo Fuori le Mura (1218). Several important mosaics from the later part of the same century reflect the trends current at that time in Byzantine and Italo-Byzantine mosaics. The mosaics by Jacopo Torriti in the apse of the basilica of Sta. Maria Maggiore (*c.* 1290–1305) are among the finest of these. They show a mingling of Western medieval and Early Christian iconographical features, such as a scene of the crowning of the Virgin surrounded by the scrolls of a fleshy, classicizing rinceaux; but the lower zone with scenes pertaining to Mary reflects Byzantine influence, an influence also seen in the technique and colour scheme of the mosaics.

Floor mosaics had a renaissance in the West that was unmatched in the Eastern Empire. In the early Middle Ages, the Byzantines developed their particular form of floor covering consisting of a geometrical mosaic made up of pieces of marble of various sizes and shapes (*opus sectile*) usually with some tessera work added for special coloristic touches. This art, called Cosmati work, spread to the West, in which, however, there was also a revival of the tesselated pavement. This pavement, which had survived the Dark Ages in a very primitive form, reemerged in Italy in the 11th century in greater splendour. There are impressive remains of such floors in many of the larger Italian churches. The fashion spread to other parts of Italy and even to France and Germany. In France, where large floors were produced in quantity in the 12th century, fragments of outstanding quality are found; for example, in Saint-Nicolas' at Reims (last half of 12th century). Cologne seems to have been a leading centre for this art in Germany. The style of the floors is usually one of simple outlines and light colours, though in some cases figures and ornaments appear against dark ground. The programs draw their inspiration from many sources, such as textiles, early floor mosaics, and the sculptural ornamentation of churches. An exceptionally well-preserved example is found in Otranto in the Italian province of Apulia, now Puglia (1163–66), where vast floors depict scenes from the Old Testament and mythology (the ascension of Alexander), representations of the Zodiac, and of the labours of the month. A profusion of monsters and fantastic animals fills out the picture of a decoration cast in the Romanesque iconographic tradition.

Cosmati work

RENAISSANCE TO MODERN MOSAICS

With the downfall of Byzantium in the 15th century, there perished that milieu in which mosaic had been constantly cultivated and had undergone continuous renewal in response to changing patterns of religious and cultural life. The art lost another foothold in Italy at the beginning of the same century, when changing attitudes about the world and about the function of art eliminated the very bases upon which mosaic had been built. One of the conventions against which the artists of the Renaissance, who were striving for pictorial realism, most strongly rebelled was the use of gold, the other-worldly element most typical of mosaic art.

The decline of mosaics

Although mosaic continued to be used to a certain extent as church decoration, it was a changed art. Some of its traditional glitter was retained, but essentially mosaics became imitations of painting. These imitative intentions were disastrous and led to the loss of knowledge of how to blend colours and handle materials. In earlier mosaics, there undoubtedly had been a distinction between the leading artist of the project, who drew the composition

Dionysus on a Tiger, from the House of the Faun, Pompeii, 2nd century BC. In the Museo Archeologico Nazionale, Naples.

Detail from the mosaic of the Nile, known as the "Barberini" mosaic, from the Sanctuary of Fortuna Primigenia, Palestrina, *c.* 80 BC. In the Museo Archeologico Nazionale, Palestrina, Italy.

and oversaw the execution, and the ordinary setters of the tesserae. The leading artist, however, almost certainly took a hand in the setting of special parts and was thoroughly trained in the technical side of the production. Now the preparatory work was divorced from the execution: the artist submitted his cartoon and left its transposition into mosaic to artisans. This drew the lifeblood from the art and caused its degradation.

In Italy, many of the great painters of the 15th and 16th centuries delivered designs for decorations in mosaic. Best known among these decorations are the works of the Venetian Luigi da Pace after Raphael's cartoon, in the dome of the Chigi Chapel in Sta. Maria del Popolo in Rome (1516), and the mosaics made after the cartoons of Titian, Tintoretto, Giuseppe Salviati, and Paolo Veronese to complete the decoration of St. Mark's in Venice. Among the greatest single undertakings of this kind was the decoration of the dome of St. Peter's in Rome, executed in the last quarter of the 16th century from the cartoons of Cavalier d'Arpino. St. Peter's also displays some of the most technically striking mosaic reproductions of paintings ever executed—the much admired altar pictures after originals by 16th- and 17th-century masters. Created for the completion and care of the large mosaics of the two great churches, the workshops attached to St. Peter's and to St. Mark's gradually became centres for the manufacture of mosaics. From them, artists were summoned for decorative work in all parts of Europe. The school of mosaics in the Vatican and the workshops in Venice still have a considerable share in the field, together with the school more recently set up for the restoration of the mosaics at Ravenna.

Nineteenth-century historicism and the breaking down of Neoclassicism's contempt for Byzantine art led to an increasing interest in and demand for mosaics. Improvements in the technique of prefabrication according to the indirect method and in the manufacture of tessera material led to a veritable mass production, which has put its mark on countless churches, town halls and opera houses. Shrill colours and a gleaming, metal-like surface characterize many of these works.

The modern revival of mosaics had several causes. Scholarship and tourism made the monuments of ancient and medieval mosaics available to an art-loving public. Painting, since the last third of the 19th century engaged in the exploitation of colour, at the turn of the century focussed on the problems of colour as the expression of psychological qualities rather than of the external world. Expressionism, which opened the eyes of artists to the art and artifacts of foreign and distant cultures, also turned their interest towards medieval mosaics. The abstract element which these mosaics contain and which springs from the latent conflict between the design and the tessera pattern made them particularly attractive to artists of the earliest decades of this century such as Marc Chagall and Giovanni Serverini. The texture of mosaic was also an attraction. An American mosaicist, Jeanne Reynal, for example, created abstract compositions in which texture is emphasized by a combination of granulated, pebble-sized, and normal tesserae, sparsely spread over a coloured base of portland cement. Many of these mosaics are small and are hung on the wall like paintings.

Mosaic's smooth yet faceted surface is ideal for decorating the large, unbroken surfaces of modern architecture. The greatest modern use of mosaic as architectural decoration is in Mexico, a country with a long tradition of folk mural painting. Realizing the potential of the medium for public enjoyment and education, the government in the 1930s and 1940s commissioned many murals with historical and political themes for public buildings. Later, it became desirable to decorate the exterior walls of buildings, and mosaic was the logical alternative to the less durable murals. Often mosaics were designed by mural painters such as Diego Rivera who, in 1953, designed the immense mosaic on the facade of the Teatro de los Insurgentes. Francisco Eppens also used historical themes in his mosaic decorations of the schools of medicine and dentistry at the National Autonomous University of Mexico (1957), as did Xavier Guerro in the Cine Ermita in Mexico City. Carlos Mérida, however, created abstract mosaic designs in the Reaseguras Alianza in Mexico City. Among the most prolific Mexican mosaicists was the architect-muralist Juan O'Gorman. Of his many mosaic works, the most important is on the exterior walls of the library of the National Autonomous University of Mexico (1951–53), which exemplifies the monumentality of which mosaics are capable. Other works executed by O'Gorman include mosaics on the SCOP, or Secretaría de Communicaciones y Obras Públicas (1952), and a stone mosaic on the facade of the Posada de la Misión Hotel in Taxco. In 1950, O'Gorman began to decorate his own house in Mexico City with phantasmagoric images and symbols from Aztec mythology.

Renaissance of the mosaic art in Mexico

Mosaic in the strict sense of the word is an art in transition. The conventional tessera mosaic is still largely in use, mainly because of the efficient production methods of modern mosaic firms; yet the distinction between this kind of mosaic and other, mosaic-like techniques is slowly being dissolved. A mixture of cubes and larger pieces of glass, ceramics, or stone is one of the variants that occurs, cubes and *objets trouvés* ("found objects") another. After World War II, experiments seem to have moved in the direction of an employment of larger, less regularly cut units. Today, mosaic is just one out of a very wide range of techniques that have as common principle the piecing together of a surface covering with the use of different durable or nondurable materials. (P.J.N.)

PRE-COLUMBIAN MOSAICS

The art of mosaic in pre-Columbian Central America was marked by a combination of great technical skill and widespread use. The representation of a mosaic mask on a stela at Seibal (an upright, freestanding stone slab functioning as a commemorative monument), Guatemala (AD 590), established the early use of the technique in Maya territory, but it became best known from the few specimens surviving from the time of the Aztec empire (*c.* 1376–1519) and from descriptions of others left by the Spanish conquerors. The Mexican lapidaries worked with obsidian, garnet, quartz, beryl, malachite, jadeite, marcasite, gold, mother-of-pearl, and shell, but turquoise above all constituted their favourite material; the excessive richness of the religious ceremonial gave wide range to its employment in ritual paraphernalia of all sorts. The incrustation was laid upon wood, stone, gold, shell, pottery, and possibly leather and native paper and was

Maya mosaics

held in place by a tenacious vegetal pitch or gum or a kind of cement.

Masks, shields, helmets, knife handles, staffs, collars, medallions, ear plugs, leggings, mirrors, animal figures, and cult statues received a covering, in whole or part, of small and irregularly shaped pieces of highly polished turquoise, cut to fit tightly together so as to form a brilliant green surface, varied at times with cabochons (a gem cut in convex form, highly polished but not faceted) of turquoise or other material. Most striking and best preserved of the surviving two dozen major specimens of this art are a mask in the British Museum, London (Figure 203), and a shield in the Museum of the America Indian, Heye Foundation, New York City. Minute pieces of turquoise, studded with cabochon turquoises, completely cover the cedar mask and are laid in symmetrical lines around the eyes and mouth and on the nose; eyes and teeth are of shell inlay. Over the wood of the shield, one panelled and three circular borders of mosaic frame a scene that may relate to the worship of the planet Venus; it is estimated that nearly 14,000 pieces of turquoise make up the decoration. A Nahuatl story of a hall at the Toltec city of Tula, the walls of which were covered with fine mosaic, may belong to legend, but a monumental use of the technique was achieved in the mosaic-like treatment of the exterior wall casing of certain buildings. Those at Mitla in the state of Oaxaca are outstanding; bands and panels of simple but striking geometric ornamentation were produced by fitting together small stones of different shapes and sizes, tenoned back into the rubble mass of the wall. Each stone was cut for the spot it occupied, and some were more deeply imbedded than others so that the designs stand out in sharp relief. The effective simplicity of design and precision of workmanship at Mitla are not matched on the elaborate Maya facades—at Uxmal and Chichén-Itzá in Yucatán, for example—where, along with geometrical designs, animal forms also occur.

Mitla and Oaxaca

STAINED GLASS

All coloured glass is, strictly speaking, "stained," or coloured by the addition of various metallic oxides while it is in a molten state; nevertheless, the term stained glass has come to refer primarily to the glass employed in making ornamental or pictorial windows. However, the singular colour harmonies of the stained-glass window are due less to any special glass-colouring technique per se than to the exploitation of certain properties of transmitted light and the light-adaptive behaviour of human vision. Rarely equalled and never surpassed, the great stained-glass windows of the 12th and early 13th centuries actually predate significant technical advances in the glassmaker's craft by more than half a century. And much as these advances undoubtedly contributed to the delicacy and refinement of the stained glass of the later Middle Ages, not only were they unable to arrest the decline of the art, they may rather have hastened it to the extent that they tempted the stained-glass artist to vie with the fresco and easel painter in the naturalistic rendition of his subjects.

Neither painting on stained glass nor its assembly with grooved strips of leading is an indispensable feature of the art. Indeed, the leaded window may well have been preceded by windows employing wooden or other forms of assembly such as the cement tracery that has long been traditional in Islāmic architecture; and the single most important technical innovation in 20th-century stained glass, slab glass and concrete, is a variation on the earlier masonry technique.

Elements and principles of design

Of all the painter's arts, stained glass is probably the most intractable. It is bound not only by the many light-modulating factors that affect its appearance but also by comparatively cumbersome, purely structural demands. And yet no other art seems so little earthbound, so alive, so intrinsically beguiling in its effect. This is because stained glass, far more directly and intensively than other media, exploits the interaction between two highly dynamic phenomena, the one physical and the other organic. The physical factor is light and all of the myriad changes in the general light level and the location and intensity of particular light sources that occur as a matter of course not only from moment to moment but from place to place—a prairie to a forest, a greenhouse to a dungeon. The other phenomenon is the spontaneous light-adaptive process of vision, which seeks to maintain orientation in all luminous environments.

Architecture, by determining the apparent brightness value of the light seen through its window openings, always establishes a definite scale of brightness values with which the stained-glass artist must work. Because the light that penetrated the interior of the 12th- and early 13th-century church took on a brilliance, even harshness, in contrast to the surrounding darkness, the artisans of the period logically composed their windows with a palette of deep, rich colours. When for doctrinal or economic reasons only clear glass could be used, it was decorated with a fine opaque mesh of grisaille, or monochromatically painted ornament, that effectively broke up and softened the light. Later, as the walls of the churches were opened up to admit more and more light, the difference between the interior and exterior light levels was no longer great enough to illuminate the dense, saturated rubies and blues of the earlier period. In the 14th and 15th centuries, generally higher keyed, drier, and more muted colour harmonies were developed. This reflected a growing preference for lighter, less awesome effects and an actual limitation that the architecture of the time imposed upon the medium of stained glass.

Role of light

The static elements of the glass and its architectural setting are modified by the element of change inherent in natural light. A seemingly endless spectrum of changes in the appearance of stained glass is a result of the changes in the intensity, disposition, atmospheric diffusion, and colour of natural daylight. The luminous life of stained glass, therefore, can best be observed by watching the organic effect of light on the window through the course of a day. If one were to enter the Cathedral of Chartres just after sunrise on the morning of a clear day, it would be to the east windows, especially those in the clerestory, that his eyes would first be drawn. They alone will have come fully to life and all of the others will still seem to half-exist in a kind of hushed twilight. Gradually, as the sun rises in the sky, these windows will become more luminous. Then the east windows will begin to lose their earlier brilliance to those all along the south flank of the cathedral, which by midday will be fairly aglow from the direct rays of the sun. The light streaming through the south windows, however, will have raised the light level inside the north windows opposite them sufficiently to create a distinct, though by no means unpleasant, muting of the radiance of the latter. If the sun at this point disappears behind a cloud and the sky becomes generally overcast, the appearance of all of the windows is immediately and dramatically altered. Because the light, now diffused, comes more or less equally from all directions, the south windows will lose some of their earlier brilliance and vivacity and the north windows will recover theirs. The overall atmosphere of the cathedral is distinctly cooler and graver in its effect, and more than ever before one begins to become aware of absolute differences in the tonality of the various windows themselves. The grisaille windows in the east end of the cathedral, the highly keyed 15th-century window in the Vendôme Chapel in the south aisle of the nave, and the three 12th-century windows over the great west portal all stand out as being substantially more luminous than the rest. If, late in the afternoon, the sun reappears, the viewer is treated to an extraordinary spectacle as the blues in the west windows, by far the most intense in the cathedral,

are further emblazoned by the direct rays of the sun. Should the main doors of the cathedral be opened, the direct rays of the late afternoon sun, streaming halfway down the nave of the cathedral, will cast a blinding pall over all the windows within their vicinity until the doors are closed once more. Then as the sky begins to redden with the setting sun, the intense 12th-century blues in the west windows lose their former intensity, and the warmer colours, especially the rubies, become so fiery and assertive that they seem almost to have displaced the blues as the predominant colour in the windows. Finally, when the sun is gone the whole cathedral is plunged once more into a deep twilight, which gradually diminishes until there is no light at all.

Insofar as stained glass may be considered an art of painting, it must be considered an art of painting with light. Whatever techniques or materials it may employ, its own most unique and indispensable effects are always the product of colouring, refracting, obscuring, and fragmenting light.

Materials and techniques

Contrary to popular belief, the glassmaker and the stained-glass artist could seldom have been the same person even in the earliest times; in fact, the two arts were rarely practiced at the same location. The glassmaking works was most readily set up at the edge of a forest, where the tremendous quantities of firewood, ash, and sand that were necessary for the making of glass could be found, whereas the stained-glass-window-making studios were normally set up near the major building sites. The stained-glass artist, thus, has always been dependent upon the glassmaker for his primary material. Coloured with metallic oxides while in a molten state—copper for ruby, cobalt for blue, manganese for purple, antimony for yellow, iron for green—sheets of medieval glass were produced by blowing a bubble of glass, manipulating it into a tubular shape, cutting away the ends to form a cylinder, slitting the cylinder lengthwise down one side, and flattening it into a sheet while the glass was still red hot and in a pliable state. It was then allowed to cool very slowly in a kiln so that it would be properly annealed and not too difficult to cut up into whatever shapes might be required for the design. Since these sheets of glass, with the exception of a type known as flashed glass, were intrinsically coloured with one basic colour throughout, changes from one colour to another in the design of a window could be effected only by introducing separate pieces of glass in each of the requisite colours.

Role of the glassmaker

Whether by accident or by deliberate intent, the glass made in the 12th and 13th centuries had almost the ideal combination of crudity and refinement for stained glass. The sheets, 10 by 12 inches (25 by 30 centimetres) in size, were both flat enough and thin enough to be cut very accurately into the necessary shapes, yet still variable enough in thickness (from less than 1/8 inch [three millimetres] to as much as 5/16 inch [eight millimetres]) to have rich transitions in the depth of their colours. With the progress of glass technology in the Middle Ages and Renaissance came the ability to produce larger, thinner, and flatter sheets of glass in a considerably larger range of colours than had been possible in the 13th century. At each distinguishable stage in this development, however, the glass became less visually interesting as an aesthetic element in its own right. The Gothic Revivalists later recognized this effect, and in the mid-19th century they initiated a return to the earlier methods of producing glass. They developed the so-called "antique" glass, which is remarkably similar in colour, texture, and shading to the glass that was used in the 12th- and 13th-century windows. "Antique" glass remains the basic material used in stained-glass windows to this day.

Traditional techniques. The art of stained glass is the translucent offspring of such earlier art forms as mosaic and enamelling. From the mosaicist came the conception of composing monumental images out of many separate pieces of coloured glass. Cloisonné enamelling probably inspired not only the technique of binding these pieces together with metal strips but that for treating the strips themselves as a positive design element. From the enamellers must also have come the near-black vitreous enamel made from rust powder and ground glass that was mixed with a mild water-based glue to form a paint. This could be used to render more or less opaquely onto glass the details of figures, ornaments, and inscriptions.

The technique of making stained-glass windows is first described in the *Schedula diversarum artium*, a compendium of craft information probably written between 1110 and 1140 by the monk Theophilus (tentatively identified as the 12th-century goldsmith Rugerus of Helmarshausen). First, a full-sized cartoon, or line drawing, of the window was painted directly onto the top of a whitewashed table, showing the division of the various colour areas into individual pieces of glass (Figure 204). Next, sheets of glass

Brunel—Ziolo

Figure 204: *Construction of a stained-glass window.* The craftsman has assembled a section of a large window on his glazing bench. Visible in the photograph are the design beneath the window and various tools for cutting glass and working the lead.

of the appropriate colours were selected and from these pieces were cut, or, more accurately, cracked away with a red hot iron. By applying the hot iron to the edge of the sheet it was possible to start a crack that could then be guided more or less in the direction in which the iron was moved, thus enabling the glazier to break away from the sheet of glass a piece of approximately the right shape and size. This he would then further shape by "grozing," or crumbling away bits of glass from its edges with a notched tool known as a grozing iron. When all of the pieces were thus accurately cut to shape, with due allowance between pieces for the leads that would join them together, the details of the design were painted onto the glass wherever necessary with vitreous enamel. The pieces were then placed in a kiln and fired at a temperature just hot enough to fuse the enamel to the glass. This done, the windows were ready for assembly with grooved strips of lead that look in cross section like the letter H. The glazier would begin by butting together on his workbench two long strips of lead, to form a corner of the panel. He would then set the corner piece of glass in place between these two leads and cut another strip of lead just long enough to surround the rest of the piece. Against this lead he would then be able to set the next piece of glass, and so on across the panel, until it was completely assembled on the glazing bench. The joints between the leads were then soldered, the panel was waterproofed by rubbing a putty compound under the leads, and it was ready for installation.

Cutting and leading techniques

Because of the flexibility of the leading it was found necessary to divide all but the very smallest windows into a series of separate leaded panels and to insert iron framing members, or armatures, between the panels. In the earliest single-figure lancet windows, such as the "Prophets" in Augsburg Cathedral (Figure 205, left), the divisions tend to be purely functional. Very soon, however, more ambitious windows became much too large to be handled in this manner. Whereas the Augsburg "Prophets" measure only about 12 square feet (1.1 square metres) in area, the Poitiers Cathedral "Crucifixion" window (Figure 205, centre) contains approximately 175 square feet (16.3 square metres) of stained glass, and the "Life of Christ" in Chartres contains more than 250 square feet (23.2 square metres). A much more elaborate system of subdivisions in the window opening, consisting of vertical as well as

horizontal members, was developed. These systems of supports often formed a geometric pattern that was incorporated in the overall design of the window. In fact, it was the ingenious conversion of this structural necessity into a positive design element that set the stage for the creation of the medallion windows of the great Gothic cathedrals. By utilizing these armatures to delineate the principal ornamental subdivisions of the windows, as in the Chartres "Good Samaritan" (Figure 205, right), the glass painters were able to fuse a complex didactic imagery and an austere architecture into one of the most compelling artistic unities of Western art. At the same time, particularly in the upper levels of a church, stone mullions began to be employed for the same purpose. The most spectacular examples are the great rose windows, in which masonry is so literally dissolved into fenestration, and the individual window opening so completely absorbed into the overall pattern, as to defy any meaningful distinction between window and wall. This perfect fusion of image, ornament, and structure, with each deriving strengths from the others that none would ever have alone, was one of the most significant turning points in the history of stained glass. From this point on the relation between stained glass and architecture begins to decline. The aims, techniques, and achievements of the stained-glass artist begin to resemble those of the fresco and easel painters, and it is by the standards applicable to the latter that the stained glass of the 14th, 15th, and 16th centuries must be judged.

Developments in the 14th century. The first significant developments in the glass painter's craft appear to have been made more or less simultaneously in the early years of the 14th century. Glass in a range of previously unavailable secondary colours—smoky ambers, moss greens, and violet—becomes generally available for the first time. The technique of staining glass yellow by painting it with silver salts is discovered (Figure 206). The glass painters also begin to develop a number of techniques for shading or modelling forms with vitreous enamel by applying translucent matts of halftone to the whole surface of the window and delicately brushing it away where highlights are desired. Darker shading is sometimes reinforced by painting on the outer as well as the inner surface of the glass. The uses of line also become increasingly refined and versatile, especially in the 15th century.

Painting and grinding techniques

To these refinements of the craft was added one wholly new technique, the abrasion of flashed glass. Ruby glass, whose unique composition made this technique possible, was a laminated glass, although it appears to be coloured

intrinsically throughout like all of the other glass in the early windows. Because the metallic agent used to produce its colour was so dense, all but the thinnest films of ruby were opaque. To obtain sufficient translucency, either the glassmaker had to suspend striations of ruby in a clear glass, thereby creating the "streaky rubies" of the early 13th century, or the glass was "flashed"; that is, clear glass while still pliant was dipped into molten coloured glass, thus coating its surface with a thin film of colour. Detailed effects, unhindered by intricate leading, could then be achieved by grinding away portions of this coloured film, first on ruby glass and then on other colours deliberately "flashed" for this purpose. To these colours could now also be added the silver salts stain in tones of yellow ranging from the palest canary tint to a deep fiery amber, depending on how heavily the stain was applied and how thoroughly it was fired. The whole gamut of more or less translucent tonalities that could be created with vitreous enamel were also used. Taken altogether, these techniques when used in combination represented a considerable liberation of stained glass from what was increasingly considered to be the "tyranny" of the lead line.

The technique of grinding flashed glass was first practiced in the late 13th and early 14th centuries; one of the earliest extant examples is in the church at Mussy-sur-Seine in France, where the windows have a blue groundwork covered all over, or diapered, with ruby roses with white centres, each rose being a single piece of glass. This type of work, however, was not common until the 15th and 16th centuries.

Later developments. At the end of the 15th century a whole new range of vitreous enamels was developed, and by the middle of the 16th century the technique of painting in enamel colours on glass began to be of major importance. In this method, granulated coloured glass of the desired colour is mixed with a flux of clear ground glass and fired onto the surface of the glass. Enamel painting was not altogether successful either technically or aesthetically, since the colours thus created were translucent rather than transparent, generally pallid, and of uncertain durability. Political disturbances in the mid-17th century created a scarcity of coloured glass throughout Europe, and gradually the traditional use of coloured glass was replaced by the new technique.

Modern techniques

Between the 16th and 20th centuries the developments in the craft of making stained-glass windows were purely utilitarian. In the 16th century the diamond glass cutter was invented, and in the 18th century hydrofluoric acid was introduced as a means of etching flashed glass. In the 19th and 20th centuries, gas and electric kilns and soldering irons were used, as were plate-glass easels upon which stained-glass panels could be temporarily mounted for painting before they were leaded. The largest palette of glass—the widest range of colours, textures, and thicknesses that the art has ever known—was also developed in the 20th century. Contemporary technical innovations include the slab glass and concrete windows developed in France in about 1930, where glass set in concrete provides an alternative to leading. In the mid-20th century such experimental techniques as bonding glass to glass with transparent resin glues were developed. Measured purely by technical standards, contemporary stained glass has never been rivalled in its versatility as an instrument of artistic expression.

Subject matter

In the Middle Ages ecclesiastical art was primarily didactic. The subjects painted in the windows played an important part in the expounding of the Scriptures and the glorification of the church and its saints.

Iconographic programs

The iconographic program of medieval stained-glass windows for ecclesiastical buildings is a product of several factors. To begin with, the cruciform plan of the churches themselves created four focal areas. Each area, by its architectural form and orientation to the sun, tended to elicit the development of certain subjects or types of subject. In Chartres, for example, the five central windows of the choir clerestory and the north rose window (Figure 207, right) are consecrated to the Virgin, the south rose window to the glorification of Christ, and the west rose window to the Last Judgment. In Bourges Cathedral the huge figures of the Apostles in the south clerestory are paired off against the prophets in the north clerestory, the representatives of the New Testament thereby receiving the full light of the sun and their Old Testament counterparts the more crepuscular light of the north sky. The great rose windows, whose circular form is itself cosmological in its implications, are invariably devoted to cosmological themes: the Last Judgment, the Apocalypse, the cycle of the year as expressed in the signs of the zodiac, the glorification of Christ and of the Virgin as the rulers of heaven. On the other hand, one of the reasons that the theme of the Jesse tree remained popular throughout the Middle Ages was that it lent itself to such a rich variety of ornamental treatments (Figure 207, left). And finally there was the will of the donors of the windows, whose personal preferences determined the subjects of many excellent works that clearly cannot be related to any comprehensive iconographic program. Some idea of the scope of these medieval enterprises can be indicated by the fact that Chartres, by no means the largest of the cathedrals, contains more than 27,000 square feet (2,500 square metres) of stained glass, in 176 windows. Of the 64 windows on the lower level, all but a few are medallion windows, which contain anywhere from 20 to 30 or more separate pictorial compositions; and the three rose windows, each more than 40 feet (12 metres) in diameter, are vast composite creations. The work of at least nine separate master designers has been distinguished in the windows of the cathedral, which was completely glazed in less than 40 years, between about 1203 and 1240.

It must be assumed that clerics supplied the master glazier with a program to which he had to conform. A 12th-century manuscript in the British Museum contains a series of circular drawings illustrating the life of St. Guthlac. These drawings might have been intended as a model for a glazier, but the scenes could equally well have been expressed in wall paintings, sculpture, or metalwork. There is more complete knowledge for the later Middle Ages. The glazier was given written instructions from which to prepare provisional sketches that were submitted for the patron's approval before being redrawn in actual size to form the final cartoon. The provisional sketch was known as a *vidimus* (literally, "we have seen"). One example of such written instructions is the program for a window given by Henry VII to the Grey Friars Church at Greenwich, England.

The *vidimus*

There is ample evidence to show that by the 14th century it was the practice of glaziers to have a stock of finished cartoons, executed on parchment or paper, which could be adapted for different glazing schemes. That these cartoons were used and reused over a long period can be deduced from the will of a York glazier, who died in 1450, in which he bequeathed to his son all his cartoons.

It is evident that in the later Middle Ages the master glazier's workshop was a highly organized enterprise, capable of producing various classes of designs, according to the expense his patrons were prepared to incur. Although the donor, cleric or layman, exercised considerable influence over the choice of subject and its manner of representation, the finished design was essentially the creation of the master glazier. The latter was often an artist in his own right, expressing in the formal language of his own technique the artistic aspirations of his time. (R.So.)

Periods and centres of activity

The evolution of the stained-glass window was a slow process. Both texts and excavation testify to the existence of stained-glass windows before the 12th century, but the textual references are too brief and nontechnical to give any clear picture of how the art evolved. The writings of the Fathers of the Latin Church—Lactantius (*c.* AD 240–*c.* 320), Prudentius (AD 348–after 405), and St. Jerome (before 420)—mention coloured glass windows in the early Christian basilicas. The 5th-century poet Sidonius Apollinaris described glazed windows in Lyon, France. Pope Leo III (795–816) is recorded to have provided windows of different coloured glass for St. Paul's basilica at Rome. Glazed church windows were widespread in pre-Carolingian Europe in the the wealthiest establishments: the Cathedral of York in England was glazed as early as 669. On the site of the Abbey of Monkwearmouth in Sunderland, England, a number of pieces of window glass dating from the late 7th century were found. Coloured green, blue, amber, and red, the edges of several pieces were grozed, or cut for fitting into a window.

In form these early medieval windows varied considerably: the actual window openings were at first filled with thin sheets of marble, alabaster, gypsum, or even wooden boards, which were pierced with holes, coloured glass being inserted into these holes. In addition to glass, other materials were used for the same purpose, thin strips of alabaster set in bronze frame being not uncommon. This form, called a "mosaic" window, persisted even in western Europe into the Romanesque period, and 11th-century examples are found in Italy in the Cathedral of Torcello near Venice and in the Church of S. Miniato at Florence.

Early leaded windows

Leading was possibly used to hold together the pieces of glass in a window opening contemporaneously with the above early methods. Leading that may have been used in window glazing dating from the 4th century has been uncovered in excavations. The earliest example of a leaded window design was a small panel (destroyed in 1918) in the church at Séry-les-Mézières, northwest of Reims in France, probably of the 9th century. It appears certain that, as at Séry-les-Mézières, many of these early windows contained coloured glass arranged in comparatively simple decorative designs, with little use of the painted design.

There is no documentary evidence even to suggest the existence of pictorial windows until the 9th century, when several rather vague references testify to the appearance of figures in German and French glass. In the 10th-century history of the Church of Saint-Remi at Reims, it is stated that the windows contained various stories.

The fragments of what may be the earliest pictorial window extant were excavated at Lorsch in Germany. It was possible to reconstruct a head of Christ, which shows some stylistic affinity with Carolingian manuscript paintings and probably dates from the 9th, 10th, or 11th century. The earliest complete pictorial windows extant are those containing five figures of prophets in the Cathedral of Augsburg in Germany, belonging to the beginning of the 12th century (Figure 205, left).

In Carolingian and early Romanesque architecture the window openings, partly for structural reasons, were small and few in number. Polychrome decoration was naturally concentrated on the large mural areas and the vaults rather than on the windows. The development of late Romanesque and Gothic architecture brought a new emphasis on fenestration and openness. It was then that pictorial windows of stained glass became a major art form and in northern Europe the most important single element in church decoration.

Although the pictorial stained-glass window is normally regarded as the invention of and indigenous to western Europe, where its development can be followed with reasonable coherency from the beginning of the 12th century onward, there is still much that is obscure about its earlier evolution. The discovery in Istanbul of stained-glass windows, apparently deriving from a tradition independent of that in the West and datable to before 1136, adds to the complexity of the fragmentary evidence already cited.

12TH CENTURY

It is probable that many of the early stained-glass windows of the 12th century displayed a single monumental figure, like those depicted on the windows in the cathedrals of Augsburg and Canterbury or like the well-known Virgin and Child known as "La Belle Verrière" at Chartres. The most important feature of the 12th century, however, was the development of the narrative window, consisting of a series of medallions painted with pictorial subjects. This type of window was, so far as is known, first used extensively between 1140 and 1144 at the Abbey of Saint-Denis near Paris. A secondary but significant development of the second half of the century was the use of allover decorative patterns, or diapers, on the groundwork adjacent to the figures. This design device was probably more common at first in Germany than elsewhere, and an early example is in the Jesse tree window (*c.* 1170–80) at Frankfurt am Main, now in the city's Städelsches Kunstinstitut.

Regional schools of glass painting in France

France. By the 12th century the production of stained-glass windows in northern Europe was considerable, and regional schools begin to be discernible, especially in France, Germany, and England. In France a number of important regional schools of glass painting emerged, one of the earliest of which was in the west. The most important works of this group include the Ascension window (*c.* 1145) in Le Mans Cathedral and the Crucifixion window (*c.* 1165) in Poitiers Cathedral. In the northeastern region of Champagne appeared another quite distinct group, whose best work is found in the Redemption and St. Stephen windows (*c.* 1150–60) in the cathedral at Châlons-sur-Marne, together with the important later windows (*c.* 1190) at Saint-Remi in nearby Reims, whose stately figures indicate that Romanesque monumentality has already begun to be tempered by the less austere, less rigorously formal mode of the Gothic.

The most important workshop in the Île-de-France region around Paris was connected with the rebuilding of the choir of the Abbey of Saint-Denis. Only fragments of these windows are left, but the three windows (*c.* 1150–55) of the west facade at Chartres are later products of the Saint-Denis workshop and are a summation of all that is most uniquely Romanesque in stained glass.

The stylistic antecedents of these schools are difficult to pinpoint. The Saint-Denis-Chartres group has certain similarities to north French manuscript paintings that are not precisely dated, and the problem is further complicated by Abbot Suger's recording that the glaziers employed at Saint-Denis came from many differnt regions. The strongly Romanesque character of the Le Mans Ascension window, its general composition, and the particular stylization of drapery forms is similar to earlier manuscript paintings from western France. The Crucifixion window at Châlons-sur-Marne, on the other hand, has precedents in general arrangement in Ottonian manuscript painting and is also closely related in style and composition to the contemporary Mosan school of metalwork centred in the valley of the Meuse River. The similarities between the two are so marked that it is not impossible that the artist worked in both mediums.

12th century German glass

Germany. There is less 12th-century glass extant in Germany than in France. The outstanding example of German stained glass of the first half of the century is the series of five prophets (*c.* 1125) in the Cathedral of Augsburg (Figure 205, left). These hieratic figures have the monumentality of design, rigidly frontal and schematic, characteristic of Romanesque art. The bold use of ruby, green, yellow, and violet glass is completely alien to contemporary French developments. In the second half of the century, art in northern Europe generally, and perhaps more so in Germany, was influenced by Byzantine models. An example is the "Moses and the Burning Bush" window now in the Städelsches Kunstinstitut at Frankfurt am Main or the Magdalen (*c.* 1170) from the church at Weitensfeld, near Klagenfurt, in Austria.

England. England has only fragmentary remains of 12th-century glass. The nave clerestory windows in York Minster contain some reused panels from a series of narrative windows, one of which depicted the life of St. Benedict (*c.* 1140–60). Another panel, a single figure of a king from a Jesse tree, shows some affinity in style with the glass at Saint-Denis and Chartres but is probably later in date (*c.* 1190). The outstanding survival from the end of the century is the splendid series of figures representing the descent of Christ from Adam, made for the choir clerestory windows (*c.* 1178–1200) of Canterbury Cathedral, which resemble the "Prophet" windows in Saint-Remi at Reims. Their features show a new humanism, and there is a sense of movement, even tension, in their bodies and draperies, comparable to contemporary English manuscript painting.

13TH CENTURY

The grisaille window

A significant feature of the 13th century was the development of the grisaille window, composed largely of white glass, generally painted with foliage designs, and leaded into a more or less complicated geometric pattern (Figure 208). This type of design was employed partly as a means of introducing a larger amount of light and partly because it was considerably cheaper than coloured glass. The combination of grisaille glass and coloured subject medallions, or figures, however, disrupted the monumental overall unity, which is a feature of a window composed entirely of coloured glass, by allowing the penetration of pure light. This change had an important effect on style; the painted design became more linear and refined, the scale more

Figure 208: Grisaille panel from the Cistercian church at Altenberg, Germany, 13th century. In the Hessisches Landesmuseum, Darmstadt, Germany.

broken and delicate. Although the combination of grisaille and medallions, or figures, is not unknown in the early part of the century, it is more common in the second half, particularly in France and England.

The movement toward humanism, partly inspired by St. Francis of Assisi and his teaching, was accompanied by a related tendency toward naturalism discernible in the visual arts in the later 13th century. The conventional formalized foliage designs of the 12th and earlier 13th centuries gave place to more natural plant motifs of oak, vine, and maple, and these break out of the formal patterns and coil with a more organic natural movement.

Styles in 13th-century French glass

France. In France, where surviving material is most extensive, the various regional schools are mostly a natural development of their immediate predecessors. There is no radical change in style or technique during the first quarter of the century. In western France the severe Romanesque style was softened and refined, as seen in the Saint-Vital window (*c.* 1200) at Le Mans Cathedral, the Saint-Martin window (*c.* 1210) at the Cathedral of Angers, and the slightly later windows of Abraham, Lot, and Joseph at Poitiers Cathedral. Another distinct workshop, centred at Lyon and responsible (*c.* 1215–20) for the apse windows of Lyon Cathedral, is characterized by a strong Byzantine influence, particularly in iconography. An important workshop in Champagne had already produced in the late 12th century the clerestory windows of Saint-Remi at Reims that foreshadowed the mature Gothic style, while later works of this atelier can be found in the clerestory windows (*c.* 1235) of Reims Cathedral and the choir clerestory windows in the Cathedral of Troyes. In the Île-de-France and eastern France the situation is complicated by the almost complete loss of the later 12th-century works. The north rose window (*c.* 1200–05) of Laon Cathedral is stylistically related to the contemporary sculptures of the facade and to manuscript painting such as the Ingeborg Psalter (Musée Condé, Chantilly). The work of this atelier is extremely distinguished, with an elegance and purity of style and a knowledge of classical art that transcend most of its contemporaries. The rose window (1231–35) of Lausanne Cathedral in Switzerland was made by a wandering artist from Picardy, Peter of Arras, and is related in style and iconography to the Laon workshop.

The most extensive glazing program of the first half of the century was at Chartres Cathedral (Figure 207, right), a tremendous enterprise that brought together various workshops from different regions. The stylistic interactions between the different workshops resulted, particularly in the second quarter of the century, in a more general similarity of style between the various regional workshops. Contemporary with Chartres are the windows (*c.* 1214–35) of the east end of Bourges Cathedral, while four windows (before 1225) at Sens Cathedral are related in composition and ornament to Chartres and Bourges and also have certain stylistic affinities with the contemporary windows at Canterbury Cathedral.

Considerable activity was also centred in the Paris area during the second quarter of the century. The major monument of the period is the Sainte-Chapelle, which was built in Paris between 1243 and 1248. Forming what amounts to a continuous wall of 50-foot- (15-metre-) high stained glass around three sides of the chapel, it contains the most extensive narrative cycle ever produced in this medium, numbering 1,134 scenes in 15 windows. Stylistically these windows are closely related to Parisian court art of the same date, and their influence can be seen in the later windows at Le Mans Cathedral (about 1254–60) and in the Cathedral of Tours (1245/55–76).

England. The only extensive remains of 13th-century glass in England are found at Canterbury Cathedral, where the 12 Theological windows were produced in about 1200 and the windows relating to St. Thomas Becket in about 1200–30. Lincoln Cathedral retains impressive fragments of a series of windows made between 1200 and 1220, but it is impossible fully to appreciate either of these series without making comparison with French work. There are important similarities between Canterbury and Sens, on the one hand, and probably between Lincoln and Paris, on the other. The glaziers, however, were probably English with a close acquaintance with French models.

Germanic countries. Thirteenth-century stained glass in Germanic countries, however, was comparatively uninfluenced by French models. It is more turbulent in design, with agitated draperies, expressive faces, and a complicated ornamented character, particularly in the backgrounds. There were many distinct regional schools, among which Cologne was an important centre. The full-length figures of saints and the Legend of St. Kunibert window (*c.* 1220–30) in the Church of St. Kunibert at Cologne have elaborate geometrical frames around the figures and scenes that are without parallel in French art. These frames are a typical feature of German work; they occur again in later work of this school in the St. Nicholas window (*c.* 1240–50) at Büchen, west of Hamburg, and elsewhere. Another workshop, which produced the Jesse tree window (*c.* 1225) in the Cathedral of Freiburg im Breisgau, shows a marked affinity with the slightly earlier enamel and metalwork produced by Nicholas of Verdun and his circle (active 12th–13th century), while the remains of a group of windows (*c.* 1230) made for the Franciscan church at Erfurt constitute a particular group strongly indebted to Byzantine models. It appears that after the completion of the Erfurt windows, this workshop, or at least some of its members, went to Assisi in Italy and also to Gotland in Sweden. The most outstanding glass of the mid-century is a related series of windows in the cathedrals of Naumburg, Strasbourg, and Frankfurt. The Naumburg window of Holy Knights and Virgins can be contrasted with the delicate mannered style of Parisian court art.

Features of 13th-century German glass

The earliest Italian examples of stained glass were the three windows executed by German craftsmen of the Erfurt school in the apse of the upper church at Assisi between 1230 and 1240. At the end of the 13th century, native designers and craftsmen produced windows. The oculus window (*c.* 1288) in the apse of Siena Cathedral has been attributed to Duccio di Buoninsegna (died 1318 or 1319), and the style of the painter Guido da Siena (active *c.* 1250–75) seems evident in the Madonna and Child panel of the Sanctuary of the Madonna della Grotta near Siena.

Early examples of stained glass in Italy

EARLY 14TH CENTURY

Stained glass of the first half of the 14th century is everywhere distinguished by an insouciant fairy tale quality and a languorous charm sometimes tinged with pathos. Regional differences, however, persisted—the gentle reserve and earthy lyricism of the English; the virtuoso painting and exquisite drolleries of the Norman-French; and the full green-, gold-, and russet-dominated palettes of the German windows. The full flowering of the Gothic style side by side with the beginnings of stylistic developments that were to culminate in the Renaissance characterized the aesthetic nature of the early 14th century. The new movement toward the representation of volume and spatial depth, by means of modelling and perspective, had its origins in Flemish and Italian painting. That the glass painter was quickly influenced by this new style is seen, for example, in the St. Anthony window in the lower church of S. Francesco at Assisi, Italy. North of the Alps the earliest extant manifestation of this new interest in perspective and modelling, based on Italian models, occurs in the chancel windows (1325–30) of the Habsburg expiatory church at Königsfelden, near Brugg, Switzerland. The knowledge of Italian models spread quickly and extensively and can be seen in France in the windows (1325–39) at Saint-Ouen in Rouen and those made about 1330 at Évreux Cathedral. In the Germanic lands proto-Renaissance spatial illusionism influenced the transept windows at Augsburg Cathedral and the east window (*c.* 1340) of Vienna Cathedral, while the earliest remaining example in English glass painting is probably the nave windows (*c.* 1330–35) of Stanford-on-Avon in Northamptonshire, England.

In the early 14th century the third dimension in canopies was still highly untheoretical and largely governed by considerations of pure design. The practice of representing a figure beneath an architectural canopy was an established convention of the 13th century, particularly used

in clerestory windows. In earlier examples the canopy plays a comparatively unimportant part in the total design, but by the end of the 13th century, although still two-dimensional, it had become more elaborate and is an important ornamental feature of the windows of Merton College, Oxford. In German and Austrian windows the canopy work is often elaborate and complex in its spatial organization; examples are found at Vienna Cathedral (*c.* 1340) and Erfurt Cathedral (*c.* 1360–70).

Currents in France and England

The art of glass painting, however, did not respond equally to these new influences emanating from Italy. It subdivides itself into two groups, of which France and England together make up one, characterized by its resistance to Italian influences. The use of perspective was purposefully restrained, so that the essential overall surface unity of the design was not violently upset, for the use of flat, patterned diaper grounds effectively counterbalanced the suggestion of spatial effect. In the first half of the century the most important work in France is found in the region of Normandy, especially in the choir windows (*c.* 1330) of Évreux Cathedral and those dating around 1325 to 1339 at Saint-Ouen in Rouen. The English glaziers of this period were extremely prolific, with Oxford, Coventry, and York as important regional centres. The nave windows of York Minster were made between 1300 and 1338 and are the largest single enterprise of this period in England. It appears probable that some of the later glass at York (*c.* 1350–70), now distributed over the windows of the choir clerestory, was the work of an imported French glazier, probably from Rouen. A flourishing school in western England, whose best work is found at Wells Cathedral and Eaton Bishop in Herefordshire, shows some affinity with German work. The best French and English work, however, has a lightness of colour and graphic refinement that is enhanced by an extensive use of yellow stain. After about 1300 the geometric grisaille glass gave way to simpler diamond-shaped pieces, painted with delicate trails of foliage and leaded together to give the effect of trellis work.

Three-dimensional style of the Germanic countries

The second group, which might be termed "Germanic"—as it embraces Germany, Bohemia, and Austria—displays a much more three-dimensional style; the colours are deeper and more saturated, the compositions are more complex, both on the surface and in depth, and the canopy designs particularly are often complicated essays in perspective; the figures are shorter in proportion and their volume more accentuated. It is brusque, almost harsh, contrasting strongly with the elegance of French and English work. All of these traits can be seen, for example, in the panels (*c.* 1350) from Strassengel, near Graz, Austria, now in the Victoria and Albert Museum, London; the earlier windows (*c.* 1350–60) at St. Maria-am-Gestade in Vienna; and at Erfurt Cathedral (*c.* 1360–70). A particular trait of this Germanic group, of which Erfurt is a good example, is a tendency to extend a single composition across the main lights of a window, ignoring the natural divisions of the stonework. The reason for this is partly architectural: the window lights are comparatively much narrower and taller than those in French or English windows.

LATE 14TH, 15TH, AND 16TH CENTURIES

The International Style

The arts from about 1380 to about 1430, which are frequently grouped together under the title of the International Gothic Style, belong essentially to an era of court art inspired by the patronage of kings, the nobility, and the higher orders of ecclesiastics. Surviving windows are extensive, and interactions between the various centres of patronage, complicated by family alliances and the exchange of works of art and artists, are particularly complex. The various national and regional styles can still be distinguished in glass painting, but there is a general tendency toward a mannered, extremely sophisticated elegance of style, sometimes verging on the precious, combined with an interest in portrait realism.

If the genius of the 13th-century stained glass lay in its epic sense of monumentality and that of the early 14th century in its warmth of human feeling, that of the late 14th and early 15th centuries is far more difficult to characterize in a phrase. The style of glass painting became at once more corporeal and more introspective. Figures are rendered with far more attention to individual human traits yet are akin in their majesty to the great prophets in the 13th-century windows. The figures painted between 1384 and 1392 by Hermann von Münster, for the west window of Metz Cathedral in France, and those painted in about 1400 by Thomas of Oxford for the chapel of William of Wykeham's College at Winchester, England, seem both newer and older than their immediate predecessors—newer in that they are beginning to bear the signature of a personal style, older in that they recall the grandeur of an earlier, essentially collective expression that now seemed everywhere to be giving way to arid cameo-like refinements on the one side and an earnest rusticity on the other.

The glass painting of this period is of high quality. The most significant examples in France are the "Royal" windows (*c.* 1395) at Évreux Cathedral. One of the most ambitious works of the period is the great east window of York Minster, made between 1405 and 1408 by John Thornton of Coventry.

In Germany and Austria there was a softening and refining of the "plastic style" of the earlier part of the century. In Austria an important atelier associated with the court produced the window (*c.* 1386–95) in the church of St. Erhard in der Breitenau and later the series of windows (*c.* 1400) at Viktring, and for the Freisingerkapella at Klosterneuburg (*c.* 1410). Germany contains a large amount of work of this period. At Erfurt Cathedral the window given by Johann von Tiefengruben (*c.* 1400) is lighter in tone and has a more refined pictorial style than the earlier windows there. The series of windows at Rothenburg, which were probably made in about 1400, should be noted, together with the cycle of windows (*c.* 1420–30) for the Bessererkapelle at Ulm Cathedral, which show an admirably refined technique.

The period 1430–1550 saw not only the decline of the Gothic style and the establishment of the new Renaissance style but also the beginning of the transformation of the art of glass painting from a significant means of artistic expression into a hybrid art form: the translucent emulation of fresco and easel painting.

The International Gothic Style continued to influence glass painting during the first half of the 15th century but to a lesser degree. Its mannered elegance and extravagant costumes can still be seen in France in the two rose windows (*c.* 1440) at Le Mans Cathedral and also the rose windows (1441–42) at Angers Cathedral. In England this aesthetic is continued in the east window (*c.* 1423–39) of the priory in Great Malvern (Worcestershire), the chapel windows (1441–47) of All Souls College at Oxford, and in the windows made by John Prudde, the king's glazier, for the Beauchamp Chapel of St. Mary's in Warwick, which were commissioned in 1447. The work of Germanic glass painters provides outstanding examples, particularly the window (after 1424) from St. Lambrecht, now in the museum at Graz, Austria, and the charming Alsatian window of St. Katherine (*c.* 1425–50) at Sélestat, France.

There were, however, important new influences affecting the styles of glass painting. In northern Europe during the first half of the 15th century a flourishing school of painting emerged in Flanders. Although the origin of the Flemish style is partly to be found in the International Gothic, a more realistic manner of representation and a detailed awareness of actuality developed that is almost the antithesis of the mannered sophistication and the essentially unrealistic world of that style.

The Flemish style

It was impossible for the glass painter to participate fully in the new realism. Glass is a translucent material; the passage of light through it is alone sufficient to create a feeling of unreality. Furthermore, although the panel or mural painter could use the new discoveries of linear perspective to heighten the sense of reality, the glass painter had to contend with the presence of the leading line, which emphasizes the surface plane. This creates a tension and a sense of ambiguity between the actual surface and the illusion of depth. Attempts were made to resolve the problems, but with little success; one result was that the lead line became increasingly divorced from the design

instead of being an integral part of it. The increasing use, from the mid-16th century onward, of vitreous enamel pigments had the effect of accelerating this process.

The full flowering of the Renaissance style in Italy and the intense interest in classical art that it stimulated resulted, in about 1500, in a profusion of ornamental details, borrowed from the formal language of classical art, in contemporary window designs. In addition the glaziers at this time often drew inspiration from contemporary engravings, particularly those of Albrecht Dürer.

The period 1450–1550 saw no decline in demand for stained glass. One of the most productive and influential areas at this time was Flanders. The six windows (*c.* 1475–1500) of the church of St. Gommaire at Lier and the Virgin window (*c.* 1482) at Anderlecht, although restored, have original portions of excellent quality and close affinity with contemporary Flemish painting.

English stained glass in the 15th century becomes more intimate, more anecdotal. It is less a cathedral art than an art of parish churches and is addressed less to an assembled ecclesia than to the individual believer. At its best it achieves a quiet intensity in the woodcut-like figures in East Harling church (Norfolk), a pathos in the Long Melford church (Suffolk) "Pieta," and a sheer power of expression in the Clavering church (Essex) "Martyrdom of St. Catherine."

The trading and political links between Flanders and England in the second half of the 15th century encouraged the influx of Flemish works of art and artists into England. A number of Flemish glaziers established themselves in Southwark, London, and some even assumed English names. The early 16th century was marked by a series of disputes between the London Guild of Glaziers and the foreigners. The latter were particularly patronized by the court and the more wealthy merchants. The two outstanding monuments of this imported style are the windows (*c.* 1480) of Fairford church (Gloucestershire) and the windows (1515–31) at King's College Chapel, Cambridge, many of which were probably designed by the Antwerp painter and engraver Dirk Vellert.

New realism in French glass painting

The spread of the new realism can be traced in French glass painting. The interactions with Flemish glaziers can be seen, for example, in the realism of the windows (*c.* 1430–40) from the Duke of Burgundy's chapel at Dijon, now in the Victoria and Albert Museum, London, which are the work of Flemish glaziers, and also the Jacques Coeur window (Figure 209) at Bourges Cathedral, which is markedly Flemish in style. Native French glaziers were extremely prolific at this time, and Normandy and particularly the city of Rouen contain an incomparable display of windows produced by a large number of distinctive workshops. The leading figures of the first part of the 16th century were Arnoult of Nijmegen (*c.* 1470–1540) and the Le Prince family at Beauvais. Arnoult of Nijmegen worked in both Flanders and France. His most important works are the windows he executed between 1490 and 1500 in Flanders for Tournai Cathedral and the Jesse window (1506) in Saint-Godard at Rouen, which is one of the most impressive examples of glass painting of the period. The works by the Le Prince family are equally impressive, particularly the Jesse tree window (Figure 207, left) in Saint-Étienne at Beauvais.

In Germany the later 15th century is dominated by the prolific activity of Peter Hemmel von Andlau (active 1430–1500) and his workshop. Examples of his work were done for St. Wilhelm's Church in Strasbourg.

In Italy a remarkable ensemble of stained-glass windows was created in the first half of the 15th century for the cupola of Sta. Maria del Fiore in Florence by some of the greatest masters of early Renaissance art: Ghiberti, Donatello, Castagno, and Uccello. Domenico Ghirlandajo created in the second half of the century windows for the Florentine church of Sta. Maria Novella. The late 15th and early 16th centuries are mainly associated in Italy with the name of Guglielmo de Marcillat (1467–1529), a Frenchman whose works display a thorough mastery of technique. His finest windows are at Arezzo Cathedral. The building of Milan Cathedral caused an important school of glass painting to develop there, and the work of Conrad Munch, a German from Cologne, and Nicolo da Varallo is noteworthy. The Milan school continued in full activity during the 16th and 17th centuries.

In Spain—especially at Seville, Leon, and Avila—there are some good 16th-century windows. They are in all cases the work of imported Flemish glass painters.

17TH AND 18TH CENTURIES

The spatial illusions of Baroque paintings were beyond the limitations imposed by the stained-glass medium. The glass painter of the 17th and 18th centuries found himself reduced to completing the cycles of stained-glass windows in medieval churches or to creating contemporary art for an architecture with no artistic affinity with traditional stained glass. The most interesting development in the late 16th and early 17th centuries was the intimate and portable heraldic panel, which became fashionable to hang in domestic windows, particularly in Switzerland, the Low Countries, and Germany. These panels, seldom more than two feet high, are the glass painter's showpieces; they complete the divorce between stained glass and architecture.

The fashionable heraldic panel

Painting glass with vitreous enamels in the 17th and 18th centuries led to the final decline of the art of stained glass. In the St. Janskerk windows at Gouda, Holland, painted by the brothers Wouter and Dirk Crabeth at the end of the 16th century, and in the works (1620–40) of Abraham and Bernard van Linge, the realization of the window as a translucent canvas painting is complete. Abraham van Linge's windows painted in 1630 to 1640 for Christ Church Cathedral at Oxford are an excellent example of the destruction of the lead line as an integral part of the design. The leading simply holds together the square sheets of glass: the effect is the same as looking at a picture set behind a rectangular grid. This type of design was continued by English glass painters such as Henry Gyles and the Price and Peckitt families, all of York, Francis Eginton, and Sir Joshua Reynolds, who designed in 1778 the west window for New College Chapel, Oxford.

19TH CENTURY

The Gothic revival that came as an offspring of the Romantic movement of the late 18th and early 19th centuries represents the beginning of a revitalization of the art of stained glass. The revival of interest in Gothic art stimulated an interest in both the technique and history of medieval glass painting. The pioneer figures in this field were E. Viollet-Le-Duc in France and Charles Winston in England. Winston was a lawyer and antiquarian who associated with various London glaziers and, with the technical help of James Powell and Sons, brought about a considerable improvement in the technical quality of coloured glass. In 1847 he wrote the first comprehensive study of the medium. The experiments were continued by W.E. Chance, who first successfully produced "antique" glass in 1863.

Revival of medieval glass painting

In the first half of the 19th century the styles and methods of the early Gothic period were reconstructed, but without much aesthetic appreciation of medieval art. Much of the work was stereotyped and mass-produced, particularly in Germany, and varied considerably in technical quality. The latter part of the century is dominated in England by Edward Burne-Jones and William Morris. Burne-Jones provided the designs and Morris adapted them to the medium of stained glass. In windows by them the lead line is once again treated as an integral part of the design, as seen, for example, in the windows for Christ Church at Oxford (1874–75 and 1878), Salisbury Cathedral (1879), and Birmingham Cathedral (1897). In the U.S. the works of John La Farge and Louis Comfort Tiffany were influential in creating an American interest in stained glass. Although the style and sentiment of 19th-century work has not been much in favour in the 20th century, the period had great historical significance in the revival of the basic technique of making stained glass.

Art Nouveau designers used stained glass decoratively for making such objects as lampshades and light fixtures, and turn-of-the-century architects increasingly employed stained glass as an integral element in wholly modern architectural settings: Victor Horta in his Hotel Solvay (1895–1910), Brussels; Antonio Gaudí in his Chapel of Santa Coloma de Cervelló (1898–1914) in the Güell Colony near Barcelona; Charles Rennie Mackintosh in the Willow Tea Rooms (1904), Glasgow; and Frank Lloyd Wright in the Coonley House (1908), Riverside, Illinois, and the Unity Church (1906), Oak Park, Illinois. These windows and panels clearly mark the beginnings of an authentically modern stained glass, despite their strictly ornamental intent.

20TH CENTURY

Three interrelated creative currents can be discerned in the development of 20th-century stained glass. First, a significant number of architects, following the lead of their turn-of-the-century predecessors and taking advantage of the new systems of fenestration made possible by modern structural engineering, have continued to discover many new ways of using stained glass. Second, especially in post-World War II France, several major easel painters turned their attention to stained glass, infusing it with many new and powerful images. Third, during the 1950s and 1960s Germany produced the first authentic school of stained glass since the Middle Ages, dedicated to exploiting the unique technical and expressive resources of the medium.

Although the bulk of significant 20th-century stained glass belongs to the period after World War II, earlier experiments, especially in France and Germany, suggested the possibilities that could be creatively explored. In Auguste Perret's church of Notre-Dame (1922–23) in Le Raincy, near Paris, the entire wall surface becomes a geometric grillwork of coloured glass by the Symbolist painter Maurice Denis. In 1930 the Dutch-born artist Johan Thorn Prikker completed a cycle of windows for the Romanesque Church of St. George in Cologne in which lead lines are used with a graphic eloquence and deep smoldering colours with a monumental gravity that have no parallel even in the greatest medieval windows.

Work after World War II

After 1946 there was an unusual burst of activity. In Le Corbusier's Notre-Dame-du-Haut (1952–55) at Ronchamp, northwest of Dijon in France, the massive south wall, 12 feet (2.72 metres) thick at the base and five feet at the top, is dramatically punctuated with a series of crude, yet remarkably effective, stained-glass windows through which shafts of light fairly explode into the church. Simultaneously, in Dominikus Böhm's and Heinz Bienefeld's Church of Maria Königin (1953–54) in Cologne-Marienburg an entire sidewall of the church is conceived as a diaphanous veil of silvery gray stained glass that half reveals and half conceals the parklike grounds outside with equally dazzling effect. In Wallace K. Harrison's First Presbyterian Church (1958) in Stamford, Connecticut, the whole central section of the church is nearly engirdled with slab glass and concrete. In all of these structures, different as they are in nearly every other respect, stained glass is seen boldly exploited once again not merely for its local ornamental quality but as a major, integral atmosphere-creating element.

The most seminal contributions of the School of Paris painters to the art of stained glass were Henri Matisse's Chapel of the Rosary (1948–52) in Vence and Fernand Léger's windows for the Sacré-Coeur (1950–52) in Audincourt. Both are by artists whose manner was rather directly translatable into stained glass. It was but a comparatively short step from Matisse's large coloured-paper collages to the disarmingly simple decorative windows in Vence, but the way Matisse used them to create an enchanting play of colour in the chaste white space of the chapel is masterful. And it took the boldly emblematic style of Léger to reveal the true expressive potentialities of slab glass and concrete. A third important work of this period is the long friezelike window created by the sculptor Léon Zack for the Church of Notre-Dame-des-Pauvres (1955) in Issy-les-Moulineaux, remarkable for its daring sequence of colour harmonies and delicate lead line motifs reminiscent of the art of Paul Klee. The stained-glass windows of Georges Braque, Jacques Villon, Georges Rouault, Marc Chagall, and Alfred Manessier are also noteworthy if less authoritative in their handling of the medium.

In Germany such distinguished prewar church architects as Dominikus Böhm and Rudolf Schwarz and the stained-glass artist Anton Wendling were able to resume careers interrupted by the Nazi era and to set the course for a whole new generation of stained-glass artists, especially in the Rhineland. Inspired by the example of Thorn Prikker, these artists have continued to explore the unique qualities of stained glass—the special refractory properties of opal-flashed antique glass, the graphic potentialities of the lead line, the bold effects of texture and relief that had become possible with slab glass and concrete—and to create a whole gamut of strange brooding colour harmonies the like of which had not been seen in stained glass since the Augsburg prophets. Among the more important works of this Rhenish school are Georg Meistermann's windows for the Dom Sepulchur (1957) in Würzburg and his complete ensemble of windows for the 15th-century church of St. Matthew (1964) in Sobernheim; Ludwig Schaffrath's cycle of modern grisaille windows for the cloister (1962–65) in Aachen, his high triple-gabled window walls for the transepts of St. Peter's Church (1964) in Birkesdorf, near Düren, and his powerfully iconic and technically innovative slab- and rod-glass sanctuary window in St. Matthew's Church (1966–67) in Leverkusen; Wilhelm Buschulte's unusually rich colour harmonies in his cycle of nave windows for the Cathedral of Essen (1964) and the choir of the Church of SS. Peter and Paul (1967) in Wegsburg, near Mönchengladbach; and Johannes Schreiter's almost monochromatic Abstract Expressionist windows for the Church of St. Margaret (1961) in Bürgstadt. Trained once again to work of the scale of the cathedral windows and to develop their art in accordance with its own intrinsic potentialities, such artists have been collaborating with some of the best architects in Germany to create the most impressive body of stained-glass windows since the Middle Ages.

(R.So./Ed.)

THE HISTORY OF GLASS DESIGN

From very early times glass has been used for various kinds of vessels, and in all countries where the industry has been developed glass has been produced in a great variety of forms and kinds of decoration, much of it of great beauty. For the composition and properties of glass and the manufacture of various glass products such as glass containers, window glass, plate glass, optical glass, and glass fibres, see INDUSTRIAL GLASS AND CERAMICS.

This section is concerned with the aesthetic or artistic aspect of glass.

Antiquity and the Middle Ages

EARLY GLASS

It is not certain in which of the civilizations of the ancient Near East glass was first made. The earliest wholly glass objects from Egypt are beads dating from some time after *c.* 2500 BC. A green glass rod found at Eshnunna in Babylonia may go back earlier, possibly to 2600 BC. A small piece of blue glass found at Eridu dates from before 2200 BC. The manufacture of glass vessels, which may have begun slightly earlier in Mesopotamia, was carried to a high point of excellence in Egypt during the 18th dynasty (*c.* 1490 onwards). These vessels are distinguished by a peculiar technique: the shape required was first formed of clay (probably mixed with dung) fixed to a metal rod. On this core the body of the vessel was built up, usually of opaque blue glass, on which, in turn, were coiled threads of glass of contrasting colour. The threads were pulled alternately up and down by a comb-like instrument to form feather, zigzag, or arcade patterns (Figure 210). The threads—usually yellow, white, or green in colour, and sometimes sealing-wax red—were rolled in (marvered) flush with the surface of the vessel. Finally, if desired, handles—often of translucent glass and sometimes of patterned "canes"—were added. The vessels were nearly always small, mainly for unguents and the like. Occasionally glass was decorated on the lapidary's wheel. Glass is known to have been made on the palace site of Tell el-Amarna, the residence of Akhenaton (reigned *c.* 1379–62 BC), and the number of fragments found in and near the palace of Amenhotep III (reigned *c.* 1417–1379 BC) at Thebes suggests that it was made there also. This palace activity seems then to have died down and after the 21st dynasty (1085–945 BC) to have ceased altogether.

Egyptian technique

Figure 210: Fish of core-made glass with "combed" decoration, Egyptian, New Kingdom, 18th dynasty (*c.* 1363–46 BC). In the British Museum. 0.141 m × .069 m.

In Mesopotamia the Nineveh tablets of the reign of Ashurbanipal (668–*c.* 626 BC) and the remains of glass in various forms excavated at Nimrūd (ancient Calah, Assyria) indicate that glassmaking was carried on there during the 8th to the 6th centuries BC. It is probable that certain vessels of palish-green or deep blue glass, cut from a solid mass as if from stone, are Mesopotamian and date from as early as the 8th century BC, as a dish from controlled excavations in Phrygia proves. A vase of this type, contrasting completely with the core-wound glass of Egypt, bears the cartouche (panel enclosing the name) of the Assyrian king Sargon II (reigned 721–705 BC), and it is probable that glass treated in this way was manufactured over a long period in Mesopotamia.

Glass was made in Greece in Mycenaean times (*c.* 1400–1200 BC) usually in the form of small molded architectural details. A few pieces suggest, however, that perhaps some vessel glass also was made by the Egyptian technique, though not in Egyptian forms. Other Aegean-area glass of this period may have been imported from Egypt.

In general, glass of the earlier half of the 1st millennium BC is scarce and displays little homogeneity. From the 6th century BC, however, glass begins to appear in great quantities once again, particularly on the Greek-inhabited islands of the Aegean, in Greece itself, in Italy and Sicily, and even farther west. This contrasts with the meagre contemporary finds on Egyptian soil. The later glasses in the old Egyptian core-wound technique were probably made in Syria or some part of the Greek world. Such vessels were still small but differ in shape from the earlier Egyptian dynastic work. They were usually decorated with light-coloured threads on a dark, usually blue, ground (familiar from the Egyptian 18th dynasty), but a notable variation was displayed in pieces decorated with dark purple threads on a white ground. In the Hellenistic period (roughly from the 4th century BC) the shapes of glass degenerated. The technique of decoration, however, remained the same; new colour combinations were used, and indeed these combinations continued into the era of blown glass.

THE ROMAN EMPIRE

In Egypt during the Ptolemaic period (330–305 BC) Alexandria came to the fore in glassmaking. By about the 1st century BC, which saw the beginnings of glass as known today, it had become preeminent in certain glass techniques. Alexandria inherited and perfected the manipulation of coloured glass rods to make composite canes, which, when cut across, revealed a design (mosaic glass). Slices from such canes could be arranged side by side to produce repetitive patterns. When, as often happens, the cane slices show starry or flowerlike designs, the resultant glass is called millefiori ("thousand flowers"). An Alexandrian technical speciality more important for the future, however, was molding, glass being pressed into, or powdered glass melted in, a mold. A combination of this process with the millefiori technique produced bowls with variegated designs in infinite variety (Figure 211). Sometimes glass of various colours was irregularly compounded to give the effect of a natural veined stone; occasionally enclosures of gold leaf in the glass simulated the glitter of natural pyrites (aventurine glass). Bowls were often finished around the rim with a cordon made of a clear glass thread twisted with one of opaque white. Sometimes such cable threads were themselves coiled round and round from a centre to make a bowl of lacy appearance, with the opaque white glass threads apparently set in a clear colourless matrix.

Dominance of Alexandria in glassmaking

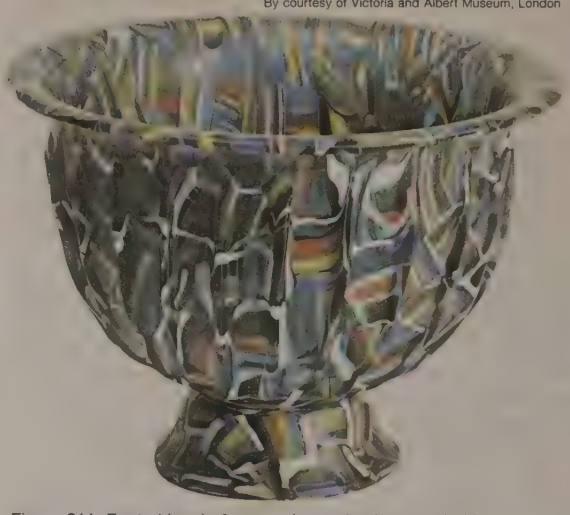

Figure 211: Footed bowl of pressed mosaic glass, probably Alexandrian, 1st century AD. In the Victoria and Albert Museum, London. Diameter 15.5 cm.

All these pieces might be finished with a fire polish by returning them to the furnace, but many mold-pressed glasses were, in fact, given a rotary polish, either by means of a spinning wheel fed with abrasives or by a process similar to lathe turning, in which the object spins and the tool is stationary. Similar equipment probably produced the numerous pieces that give every appearance of having been cut from a solid block of glass or at least from a thick, mold-pressed blank. Such pieces (usually flat dishes or two-handled cups) follow the contemporary forms of pottery and metalwork. Wheel engraving appears to have become an Alexandrian specialty around the 1st century

BC and probably continued so throughout the two succeeding centuries. Alexandrian wheel engravers produced not only massive cut shapes, but also intaglio (incised) and relief surface decoration, the latter by laboriously grinding back the surface of the glass to form a background for the design. Simple motifs such as lotus buds or lotus flowers were produced in this way and occasionally more elaborate figural compositions were also done. Other specialties attributed to Alexandria were enamel painting (pigments mixed with a glassy flux were fused to the surface of the glass vessel by a separate firing) and an extraordinary technique of sandwiching a gold leaf etched with a design between two layers of clear glass.

Introduction of blown glass

The most important innovation in the whole history of glass manufacture was blowing. Perhaps by a stroke of pure inventive genius it was perceived that glass on the end of a hollow metal tube could be blown into a mold as easily as it had theretofore been pressed in. The next stage was to use molds for forms, such as flasks, that could not be made by pressing. Finally, it was realized that the glass bulb on the end of the blowpipe could be shaped freehand to any form desired, and handles, feet, and decorative elements could be added at will. This liberating discovery, probably made during the 1st century BC, gave rise to the astonishing growth of the glass industry in Roman imperial times. In addition to the luxury vessels of types already described, which were produced with an elaboration of skill that astonishes and often baffles the modern technician, commercial containers in great variety were mass-produced in common greenish glass on a scale that was not matched until the 19th century.

The discovery of glass blowing may well be credited to the Syrian glassworkers, since the first mold-blown glasses bear the signatures of Syrian masters and since the readily ductile Syrian soda glass was especially apt for this purpose. Syrian glassworkers, however, seem to have migrated wherever demand promised a ready market, and some masters of mold blowing appear to have moved to Italy early in the 1st century AD; in the course of that century Italy became an important glass-producing area. Glass engraving especially seems to have flourished there and particularly one form of the art—grinding through an opaque white layer to a darker ground (cameo glass). The most famous example of this exacting technique is the Portland vase, in the British Museum, London. The capacity of the Italian glass craftsman to surpass all earlier masters in work of the most complex character is seen in the so-called cage cups (*diatreta*), on which the design—usually a mesh of circles that touch one another, with or without a convivial inscription—is so undercut that it stands completely free of the body of the vessel, except for an occasional supporting strut (Figure 212). These cups were made perhaps at Aquileia and date from the 3rd and 4th centuries.

Cameo glass engraving technique

Parallel to the pottery industry, glassmaking spread from Italy to northern Gaul, in particular to the valleys of the Rhône and the Rhine. In Britain the industry was probably not of great importance. The Rhineland, however, became one of the great glassmaking areas of the Roman world (partly, it is thought, because of successive migrations of Near Eastern workers) and, although Rhenish glass is always recognizably Roman, several types of decorated glass were specialities of the district. Glasses decorated in serpentine patterns by threads trailed on and then pressed flat and notched are perhaps the most important and typical (*Schlangenfadengläser*). A considerable school of glass engraving also seems to have flourished, probably around Cologne. Although some engraving shows an impoverished linear style eked out by lines scratched with a hard stone point, some is executed by means of wheels sufficiently thick to permit rounded cuts corresponding to the modelling of the human figure, and simulating it when the piece is seen against the light. Both types of decoration flourished in the 3rd and 4th centuries.

In Egypt in the later centuries of the Roman epoch glass was in frequent use for tableware, but artistic standards were not high. Plain dishes, cups, bowls, and lamps are characteristic; the glass of such tablewares ranges from an almost colourless "metal" (basic glass) of good quality to

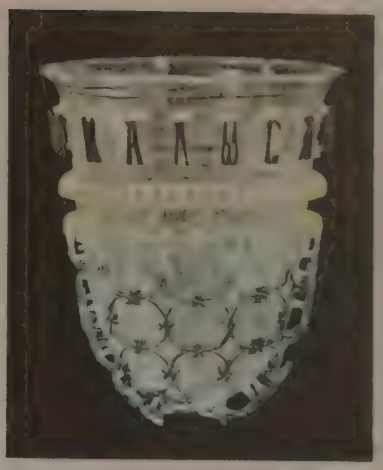

Figure 212: An example of *diatreta* ("cage cups"), perhaps made for a Greek living in the Rhineland, 3rd to 4th century AD. In the Römisch-Germanisches Museum, Cologne. Height 12.1 cm.

By courtesy of Romisch-Germanisches Museum, Cologne

a greenish brownish substance full of bubbles and impurities. Decoration in this late period is mainly restricted to a few rough-cut lines, an occasional group of coloured glass blobs on the lamps, or a zigzag trail of glass thread running between the lip and the shoulder of a vase. In Syria during the same period, however, this trailing technique, which was particularly suitable to the ductile Syrian material, was carried to extreme lengths—threads circling the body or neck of a vessel, a profusion of zigzags, and fantastically worked handles.

Syrian use of trailing technique

With the breakdown of the Roman Empire, glassmaking fared differently in different parts of the world. In the East, urban life continued relatively undisturbed, and glassmaking evolved in an unbroken progress into Islāmic times. In the northern provinces, however, glassmaking became an affair of small, often isolated, glasshouses working in the forests that supplied them with fuel. Relatively simple shapes were made of an impure greenish or yellowish material, and decoration was restricted to simple trails of thread. Considerable virtuosity, however, was displayed from *c.* 500 onward in the manufacture of the elaborate

By courtesy of the trustees of the British Museum

Figure 213: *Rüsselbecher* Frankish glass, probably 7th century AD. In the British Museum. Height 19.0 cm.

and fantastic *Rüsselbecher* ("elephant's trunk, or claw beaker") on which two superimposed rows of hollow, trunklike protrusions curve down to rejoin the wall of the vessel above a small button foot (Figure 213).

In the East, Syria appears to have continued its predilection for trailed and applied ornamentation. In Egypt the art of glass suffered a catastrophic decline; only small rough vessels of impure green or blue material were manufactured.

BYZANTIUM

In Byzantium itself the position of glassmaking is obscure. A distinction was made between *vitrarii* ("glassmakers") and *diatretarii* ("glass cutters") in edicts of Constantine the Great, Theodosius, and Justinian—suggesting that cutting played an important part in Byzantine glass decoration. This is borne out by the fact that cut glass made up the greater part of the glass that was brought back from the sack of Constantinople by the crusaders and placed in the treasury of St. Mark's in Venice. Apart from a few pieces of obviously Roman glass, presumably kept as heirlooms in Byzantium, these glasses are decorated either with tessellated (mosaic) patterns of overlapping round or oval facets or with round bosses in relief. These same two forms of cutting are observable in glass of the 5th century excavated at Kish in Mesopotamia; it is a fair assumption that Byzantine taste in glass, as in some of the other arts, was strongly influenced by the East. It is probable, however, that some enamelled and gilt glass also was made in the Byzantine provinces (*e.g.*, in Corinth), if not in Byzantium itself.

Glass from the sack of Constantinople

ISLĀM

In the 7th century the whole Near East was overrun by the Arabs, and a number of rival dynasties were established in different parts of the conquered territory. An Islāmic civilization developed comparable to the preceding area of Greco-Roman culture, and a distinctively Islāmic glass style evolved. Although often it is not possible to say where a particular glass was made, different parts of the Islāmic world seem to have shown predilections for one or another type of glassmaking. In Syria, pieces more or less heavily decorated with trailed threads or applied blobs and pieces blown in molds, patterned with ribs or other allover designs, were still made. In Mesopotamia, glassmaking and, in particular, engraving flourished, especially during the ʿAbbāsid dynasty (750–1258), and attracted many of the best artists in the Islāmic world. Not only were the earlier modes of facet and boss cutting continued, but (perhaps deriving from them) two splendid new styles were created, one of linear intaglio, the other of relief cutting (outlines were left in relief by cutting back the ground and were then enlivened by crosshatching). Bowls, bottles, and ewers of remarkable sumptuousness were decorated with forms of running animals and plant scrolls. The quantity of engraved glass of these types found in Persia suggests that such work was done there also.

In Egypt there was both innovation and, after the post-Roman period, a notable revival of earlier techniques. Among the innovations was the stamping of glass by means of tongs, one jaw of which was patterned. The technique also is found in other lands. One extension of it, by which a bottle's upper and lower halves, made separately in contrasting colours, were decorated by the tongs and then joined together, was probably a Syrian innovation. More important was the Egyptian invention of lustre painting. In its simplest form it consisted of painting with a pigment containing silver that when fired in a smoky atmosphere (*i.e.*, without oxygen) produced on the glass a thin, metallic film that varied in colour from pale yellow to brown. Intact bowls and a bottle decorated by this technique exist, but whole classes of much more elaborate lustre-painted glass are represented only by fragments. A very wide variety of sumptuous polychrome effects are represented, although many were probably not produced by lustre properly so-called. The technical processes by which these effects were achieved are not yet understood.

Egyptian tong stamping and lustre painting

Egyptian Islāmic revivals in glass included millefiori effects, found mainly in plaques for wall decoration, and white fern and feather patterns that were produced on dark glass vessels by combed and imbedded glass threads. Glass cutting was also practiced in Egypt, primarily for the production of deeply incised small perfume bottles of square sections, the bases of which were often cut into four tapering feet ("molar tooth" bottles). It seems probable that in Egypt was also perfected the techniques of gilding, decisive for the next phase in Islāmic glassmaking. In gilding, gold leaf is applied to an object that is then fired to fix the glass.

Glassworkers migrating from Egypt to Syria after the fall of the Egyptian Fāṭmid dynasty in 1171 may have laid the foundation of the Syrian art of enamelled and gilt glass. Although earlier phases of this art are incompletely understood, the first group of enamelled and gilt glasses seems to be one in which thick enamels are used (particularly white and turquoise blue), often in series of beadlike drops; this group is tentatively associated with the town of Raqqah in Syria. A similar doubt surrounds the origins of two broad families into which Syrian glass of the 13th century is divided. One, characterized by the use of thick, jewellike enamels, is connected with the town of Aleppo; the other, notable for its exquisitely painted small-scale figural decoration, is attributed to Damascus.

Syrian enamelled and gilt glass

Both cities were famous for their glass at this time, but it is uncertain what each produced. Wherever made, these two types of glass represent one of the highlights in the history of the art, whether one considers the rich green, red, yellow, white, and turquoise-blue enamels of the "Aleppo" group or the masterly red outline drawing of the "Damascus" group.

Toward 1300, Chinese influence, infiltrating by way of the Mongols and Tatars, makes itself felt in the decoration of these glasses (Figure 214), as is apparent in the series of great mosque lamps that then began to be inscribed with the names of rulers and great officers of state in Egypt. From a peak of excellence at the beginning of the 14th century a decline set in, greatly precipitated by the Mongol conqueror Timur's sacking of the chief Syrian cities at the end of the century.

Damascus fell finally in 1400, and it is recorded that the glassworkers of that city were carried into captivity in Samarkand. Nevertheless, some enamelled glass of in-

ferior quality continued to be made in the 15th century, perhaps in Egypt. By the end of that century, however, there is evidence that mosque lamps were being made in Venice for the oriental market and the great Near Eastern tradition of enamelled and gilt glass was clearly moribund.

Mid-15th to mid-19th century

VENICE AND THE FAÇON DE VENISE

A glass industry was already established near Venice in the 7th century, and vessel glass was made there by the last quarter of the 10th century. In 1291 the glass furnaces were removed to the neighbouring island of Murano to remove the risk of fire from the city. Although Venice had constant contact with the East, there is no evidence that it was indebted to that source for its skill in glassmaking. Venetian enamelled glasses (Figure 215) appear in the second half of the 15th century, and, although their technique is essentially similar to that of the Syrian glassmakers, it is likely that they are of independent development. Little is known of the vessels made before this period, but it is evident from representations in pictures that they were mainly footed flasks and low beakers. The Venetians attributed the introduction of enamelling to a member of the glassmaking family of Barovier. The earliest pieces known, commencing with a goblet dated to 1465, certainly show no signs of outside influence. These, like most Venetian glass of the period, were inspired by the artistic ideals of the Italian Renaissance. The decorations represent triumphs, allegories of love, grotesques (fanciful combinations of human and animal forms), and so forth, with borders of dots of enamel laid on a ground of gold etched in scale pattern. Many of these pieces were of richly coloured glass, blue, green, or purple.

The Venetians were keenly aware of Roman achievements in glassmaking as in the other arts; they reproduced mosaic, millefiori, and aventurine glass, and glass resembling natural layered stones (*calcedonio*, sometimes miscalled *Schmelzglas*), and they even copied a Roman form of bowl that had vertical, external ribs. All these types of glass were Venetian specialities, and they were probably developed as a part of the extensive local bead industry.

Clear, colourless *cristallo* glass

The greatest achievement of Venice, however, and that upon which its great export trade came to be based, was the manufacture of clear, colourless glass, which was apparently exclusive to Italy during the Middle Ages (Figure 216). From its resemblance to natural crystal, this material was called *cristallo*, although in fact it often has a not unpleasing brownish or grayish cast. Made with soda, it was very ductile and cooled quickly. It therefore demanded of the workmen great speed and dexterity, and this, in turn, affected the nature of the glasses made. In the first half of the 16th century the Venetian glassblowers produced glasses of an austere simplicity. As the century proceeded (and more markedly still in the 17th century), however, there was a tendency to produce elaborate and fantastic forms. Enamelling on glass went out of fashion in Venice (except on pieces for export) in the first half of the 16th century. Its place was taken to some extent by the use of opaque white glass threads for decorative purposes (latticinio). This form of decoration became progressively more complex (Figure 217); opaque threads were embedded in a matrix of clear glass and then twisted into cables, which were themselves used to build up the wall of a vessel. The height of complexity was reached when a bulb of glass decorated with cables or threads running obliquely in one direction was blown inside a second bulb with threads twisted in the other direction. The composite globe thus formed was then worked into the desired form. This resulted in a vessel completely covered with a lacy white pattern (*vetro di trina*). Other methods of decoration at this time were mold blowing and dipping a vessel while hot into water or rolling it on a bed of glass fragments to produce a crackled surface (ice glass). *Cristallo* was also found suitable for engraving with a diamond point, a technique which produced spidery opaque lines that were especially suitable for delicate designs. The technique seems to have come into use about 1530.

Spread of Venetian glass-making

The glassworkers of the island of Murano were forbidden to leave Venice or to teach their secrets to outsiders, under dire penalties both to themselves and their families. Such was the demand for Venetian glass in the rest of Europe, however, and such was the desire of kings and nobles to control and reap the profits of its manufacture, that many Venetian workmen in the course of the 16th century were tempted to abscond to other countries, where they helped to set up glassworks. Furthermore, at Altare, near Genoa, existed a second great centre of glassmaking. Its glass was so like the Venetian in style and material that it is nowadays impossible to distinguish between the two. The

glassworkers at Altare, moreover, were governed by no such laws as the Venetians; rather, they made it their policy to supply their men and teach their methods wherever there was a demand. Thus, the fugitive Venetians and the willing Altarists spread the Italian art of glass to the rest of Europe, and glasshouses were established in France, Spain, Portugal, Austria, and Germany, while in the North, Antwerp was a secondary source of diffusion.

Italian glassworkers ranged as far north as England, Denmark, and Sweden. Their labour was necessarily diluted by that of native workmen to whom they were often required to teach their methods. Variations in locally available raw materials modified the quality of the glass, and local taste influenced the form and ornamentation of the objects they produced. Nevertheless, in the late 16th and the 17th centuries an international style in glass developed, wholly Italian in origin and inspiration (*façon de Venise*).

Although there was everywhere a family likeness among glasses of the *façon de Venise*, certain countries developed types peculiar to themselves that are worthy of mention. Thus in Spain not only were fantastic and even bizarre shapes evolved in green glass, but in Barcelona a characteristic kind of enamelled decoration was developed, the peculiarities of which include a light-leaf-green colour and a constantly recurring lily-of-the-valley motif (late 15th–16th century). Elsewhere, at Hall, in the Tirol, a characteristic decoration with the diamond point, often supplemented by cold painting (*i.e.*, unfired oil—or other paint applied to a finished object), was favoured in alternating broad and narrow upright panels containing symmetrical scrollwork or coats of arms and other devices. Almost equally stiff and formal diamond-point work is to be seen on glasses probably made at the London glasshouse of Jacopo Verzelini (examples dated between 1577 and 1590). A more promising development of diamond-point engraving occurred in the Netherlands. There too the work of the 16th century was relatively formal and stiff, linear and clear, with simple hatching only. In the succeeding century, however, diamond-point engraving became initially more supple and pleasing, only to degenerate eventually into over-elaboration.

Diamond-point engraving in the Netherlands

Diamond-point engraving was practiced there widely by talented amateurs in the 17th century, among them Humanists such as Maria Tesselschade Roemers Visscher, her even more famous sister Anna Roemers Visscher and Anna Maria van Schurman. The latter two decorated their glasses with flowers and insects drawn with a gossamer touch, often accompanied by epigrams in Latin or Greek capitals scratched with severe precision or in the free scrolled style of the Italianate writing masters of the time. A similar calligraphy was practiced later in the century by the amateur Willem Jacobsz van Heemskerk, with notably beautiful results.

Engraving in the first half of the 17th century gradually abandoned linear clarity in favour of crosshatched chiaroscuro (shading) effects, the highlights formed by sometimes completely opaque spots. Many artists worked in this manner; two are worthy of special mention. One was an accomplished engraver signing "C.J.M.," whose earliest dated glass is of 1644; the other was Willem Mooleyser, of Rotterdam, who worked in the last two decades of the 17th century with a scribbled freedom and vigour that raised his work above the average. By the end of the century this type of diamond-point work was superseded in popularity by wheel engraving.

GERMANY

In Germany toward the end of the 17th century a reaction to Venetian glass styles seems to have set in. In that country there had been a continuous survival, probably from late Roman times, of a local type of green glass, a product of forest glasshouses made with potash obtained by burning forest vegetation and called therefore Waldglas ("forest glass"). From this material, often of great beauty of colour, were made shapes peculiar to Germany, notably a cylindrical beer glass studded with projecting bosses, or prunts (*Krautstrunk*, or "cabbage stalk"), and a wineglass (*Römer*) with cup-shaped or ovoid bowl set on a similarly prunted hollow stem (Figure 218). This became the classic

The Waldglas tradition

German shape of wineglass, which survived into the 18th century and, with modifications, to the present day. Apart from these indigenous forms, German glass in Venetian-type *cristallo* developed local characteristics of its own in the latter part of the 17th century.

In Nürnberg, for instance, the tall-stemmed Italianate goblet underwent a transformation into a severe glass with stem composed of no more than a baluster-shaped element and a bulb, which were joined together by a number of disk-shaped elements, or mereses, and attached to foot and bowl by the same means. Such goblets display some of the most accomplished glass engraving that has ever been practiced.

The leader and founder of the Nürnberg school of engravers was Georg Schwanhardt, a pupil of Caspar Lehmann. Lehmann had been gem cutter to the emperor Rudolf II in Prague and there had taken the decisive step of transferring the art of engraving from precious stones to glass. His first dated work is a beaker of 1605; in 1609 he obtained an exclusive privilege for engraving glass. Although he is the first great personality in glass engraving, he was not the first to practice the art in the German area.

On Lehmann's death in 1622 Schwanhardt inherited his patent and moved to his own native city, Nürnberg, where a whole school of glass engraving grew up around him and his family. Schwanhardt's work is characterized by delicate, tiny landscapes, often accompanied by bold formal scrollwork. His son Heinrich excelled in minute landscapes but also engraved inscriptions of fine calligraphic quality. Other notable Nürnberg engravers of the late 17th century were Paulus Eder; Hermann Schwinger, a master calligrapher; and H.W. Schmidt and G.F. Killinger, both notable for the delicacy with which they rendered landscapes. Somewhat similar work was done at Frankfurt am Main by members of the Hess family.

In Bohemia, after Lehmann's death, little engraving of high quality was done. Just before 1700, however, with the perfection of a massive, crystal-clear, potash-lime glass that allowed cuts of considerable depth, the engravers of the Bohemian–Silesian area came into prominence. The harnessing of the mountain streams in the Riesengebirge for water power enabled engravers (those of the Hirschberger Valley in particular) to practice relief engraving, which demands immense energy for grinding down the background of the design. Massive covered goblets were decorated with powerful acanthus scrolls in the contemporary baroque taste. Relief engraving (*Hochschnitt*) was only occasionally used by itself in the Bohemian–Silesian area in the 18th century; more often it was employed in conjunction with intaglio (*Tiefschnitt*). By the turn of the 18th century the engravers of this area—anonymous workmen regarded as artisans rather than as artists—had acquired great technical skill; this enabled them to adapt to glass all the changing fashions of the 18th century in the decorative arts. Glass engraving, often of fine quality, was also practiced in many parts of Germany—notably Thuringia, Saxony, and Brunswick—but the most significant work of the late 17th and early 18th centuries was that done in Brandenburg. There, the glassworks at Potsdam (moved to Zechlin in 1736) produced massive goblets and beakers that were engraved—usually to order for the court—in Berlin, where a water-powered engraving shop had been installed in 1687. Both relief and intaglio engraving were practiced, the latter being favoured. This workshop, indeed, produced perhaps the greatest of the German intaglio engravers, Gottfried Spiller, whose deep cutting on the thick Potsdam glass has seldom, if ever, been surpassed (Figure 219). A notable, if lesser, engraver from the same shop was Heinrich Jäger; and later, in the 1730s and 1740s, work of high quality was done by Elias Rosbach.

Bohemian relief and intaglio engraving

Another workshop of great significance was established toward the end of the 17th century at Kassel, in Hesse. There perhaps the greatest of all the relief engravers, Franz Gondelach, handled glass with a truly sculptural feeling.

In the second half of the 18th century, engraved glass declined in favour, although the technical skill required for its production never died out in the Bohemian–Silesian area. It experienced a great revival in the second quarter of the 19th century, when the taste of the newly prosperous bourgeoisie favoured elaborate decoration. The engraving of this period is often skillful in the extreme, although marred by excessive naturalism. Striking innovations of the period were the use of a casing (normally ruby red, blue, or opaque white) through which the design was cut down to the colourless glass. A yellow coating (the silver stain of the stained-glass artist) was often used in the same way. Notable engravers of this epoch were Dominik Bimann, August Böhm, A.H. Pfeiffer, and members of the Pelikan and Simm families.

German enamelled glass

Second in importance only to engraving as a method of decorating glass in Germany was enamelling. Germany had proved a profitable market for enamelled Venetian glass during the 16th century, and, in the latter part of that century, glass enamelling began to be practiced in the Germanic lands themselves, most notably in Bohemia. This enamelling, in bright opaque colours, was much favoured throughout the 17th century, chiefly on the cylindrical drinking glasses, often of great size, known as *Humpen* (Figure 220). The glass they were made of was often impure and of a greenish or yellowish cast, while the painting itself was the simplified repetitive work of artisans rather than of original artists. Nonetheless, the gaiety of colour of these glasses and a certain naïveté in their painting give them an authentic unsophisticated charm. The most favoured types of decoration include a representation of the imperial double-headed eagle (*Reichsadlerhumpen*); representations of the emperor with his seven electors, either seated or mounted on horseback (*Kurfürstenhumpen*); subjects from the Old and New Testaments; and allegorical themes such as the Eight Virtues and the Ages of Man. These were painted between borders of multicoloured or white dots or intersecting ellipses, often on a gold ground. This general style continued into the 18th century; but in the course of that century the levels of artistic and technical competence sank, and the tumblers and spirit bottles, which were the main types produced, can be regarded only as objects of peasant art.

The *Schwarzlotmalerei* technique

A far more sophisticated type of enamel painting was carried on during the third quarter of the 17th century at Nürnberg. There, painting in black or sepia (*Schwarzlotmalerei*)—a technique borrowed from the stained-glass artist—was used to decorate the small cylindrical beakers (often resting on three hollow ball feet), which were a locally favoured shape. Other colours, notably red used in touches with the black, were occasionally employed. The greatest and most original artist of this school was Johann Schaper, who painted delicate architectural and landscape compositions in which a fine point was used to etch in details (Figure 221). The best of Schaper's followers were J.L. Faber, Hermann Bencherlt, Johann Keyll, and Abraham Helmhack, but none of them equalled him in artistic competence. Comparable work appears to have been done, although on a more restricted scale, in the Rhineland, notably by Johann Anton Carli of Andernach. At the beginning of the 18th century *Schwarzlot* painting, often with touches of gold, was practiced in Bohemia and Silesia and reflected the changing fashions in the decorative arts. Daniel Preissler and his son Ignaz are known to have done this work.

In the first half of the 19th century the decorators of vessel glass once again borrowed from the stained-glass artist. Samuel Mohn, his son Gottlob Samuel Mohn, and Anton Kothgasser painted the beakers typical of this "Biedermeier" period in transparent enamels and yellow stain.

Figure 222: *Zwischengoldglas* ("gold sandwich glass"), double-walled beaker decorated with a bear hunt, Bohemian, c. 1730. In the Kestner-Museum, Hannover, Germany. Height 8.9 cm.

The *Zwischengoldgläser* technique

A technique peculiar to Bohemia in the 18th century was that of the "gold sandwich glasses" (*Zwischengoldgläser*). These were beakers or less often goblets made of two layers of glass, exactly fitting one over the other, between which was sandwiched a gold leaf previously etched with a steel point to the desired design (Figure 222). The earliest work in this technique was anonymous, but late in the century J.J. Mildner employed it with notable success, making gift tumblers decorated with medallions of etched gold or silver leaf (often backed with red pigment) and sometimes also engraved on the wheel or with the diamond point.

ENGLAND

Glass was certainly made in England during the later Middle Ages, but most of it was used for church windows (see *Stained glass*). The vessel glass of the period has not been much studied and is only imperfectly understood. Only by the second half of the 16th century does the picture become clearer. Two lines of development may be traced in this period. One is the glass of German waldglas type, made in the woods that supplied the furnaces with fuel and a source of potash. These glasses were made by workers whose traditions were those of Lorraine and northern France. Much of their production was of window glass, but they also made vessels in a modest variety of shapes and modes of decoration. Chief among them was a tumbler-like drinking glass with a low, double foot-rim produced by pushing in the bottom of the bulb from which the glass was made; this might be decorated either by mold-blown diaper (overall repeat) patterns, by swirled ribbing imparted by mold blowing and subsequent twisting, or by a zone of trailed threading below the rim. Applied notched ribbons or small circular motifs also were used. Small bottles of mold-blown hexagonal section or of flattened ovate form with diagonal ribbing also were made. The second line of development was that of the international Venetian style brought by immigrant Italians; this, however, in time acquired an English idiom. The work was done mainly in London.

17th-century English glass

In the 17th century these two traditions were welded into one, spurred by the proclamation of 1615 that forbade the use of wood in glass furnaces, as well as in certain other industries, in an effort to prevent the deforestation of the country. Thereafter, with coal as the sole means of fusing glass, glassworks tended to be located where coal deposits (and the frequently concomitant fire clays for making glass pots) were abundant. Since such areas for the most part were those that have been continuously occupied by industry (*e.g.*, the Stourbridge area and Tyneside), exploration of the early glass factory sites has seldom been practicable. Little, therefore, is known of provincial glassmaking in England in the 17th century, but it is clear that Venetian influences gradually replaced the earlier waldglas tradition, which had depended on supplies of wood. Some idea of the new style may be gained from the fragments of glasses often excavated in London and other cities. It is frequently difficult to distinguish between an English glass and an imported European one, although a certain coarseness may be taken as symptomatic of English make.

During the first half of the 17th century, glassmaking was among the English industries for which monopoly rights were granted by the crown; the greatest of a series of monopoly holders was Sir Robert Mansell, who effectively controlled the industry from 1623 until his death in 1656. After the Restoration, although some monopolies were granted for certain categories of glasswares, an increasingly important role in the English industry was played by the Worshipful Company of Glass Sellers (reincorporated in 1664), which was able to keep closely in touch with the needs of the English market. Its members seem to have laid stress on simplicity of shape and durability of material, as appears from the correspondence of one of them, John Greene, with his suppliers in Venice. Dissatisfied with the quality of glass supplied to them and no doubt also anxious to make England independent of foreign sources of both finished glass and raw materials, they commissioned George Ravenscroft to make experiments with

native materials in the hope of evolving a more solid glass than the Venetian and one that more closely resembled rock crystal.

Discovery of lead glass

Ravenscroft was completely successful; his crucial discovery was the value of adding lead oxide. His "glass of lead," evolved about 1675, was perfected toward the end of the century and set a standard for the rest of Europe. It was solid and heavy and more durable than the Venetian-type glass, which it progressively displaced. It was also characterized by brilliance and dark shadow paradoxically combined. It was slower to work than the Venetian glass and gradually the Venetian idioms were dropped from English glassmaking in favour of a genuine native style. This style is best exhibited in the drinking glasses that, by the end of the 17th century and the beginning of the 18th, constituted the chief glory of the English industry. These often massive baluster-stem glasses were composed of a usually funnel-shaped bowl and a stem compiled of any of a large variety of pear-shaped and bulbous knops (ornamental knobs). In their simplicity and the harmony of their proportions they rank among the classics of the Queen Anne style.

Toward the middle of the 18th century, taste in the arts generally inclined to lighter forms, and in glass this tendency was given additional impetus by an excise (1745–46) levied on glass by weight. Drinking glasses became slighter, the bowls smaller, and the stems taller and more slender. The loss in architectonic values was often offset by extraneous decoration. At first this tended to be concentrated in the stem. Bubbles of air had sometimes previously been enclosed in a knop forming part of the stem of a wineglass, and these bubbles were now drawn out and twisted so that they formed a cable of air ribbons inside a cylindrical stem. Stems of this type were popular about the middle of the century. Just before 1750 a stem decorated with threads of opaque white glass instead of air twists came into favour. These stems were made by much the same techniques as the Venetian latticinio glass. They remained in fashion until about the time of the second Glass Excise Act in 1777, which imposed a tax on the opaque white "enamel" glass, previously exempt.

These forms of ornament had been restricted to the stems of glasses, but other methods of decoration were simultaneously evolved to embellish the whole glass. First of these was engraving, which had been sporadically practiced in England as early as the end of the 17th century. This work and the inscriptions, coats of arms, and arabesque borders in German style that were engraved during the first 20 years or so of the 18th century were undoubtedly the work of immigrant (probably German) artisans. By 1735, however, at least one English engraver was capable of executing such commissions and from about this time engraving on glass began to take on a more English character. An artless use of floral motifs, chinoiseries (Chinese themes), and scenes from country life is typical of the engraving of the third quarter of the 18th century, as were the frequent representations on glasses of Jacobite themes—portraits of the Old and Young Pretenders (James III and Charles Edward), the rose with buds, the honeysuckle, and the other flowers used in the symbology of the Stuart cause, together with the mottoes of such "loyal" societies as the Cycle Club.

Development of engraving and enamelling in England

Engraving never reached great heights in England, but English glasses were in demand by engravers in Europe, particularly in the Netherlands, where the work of at least one notable artist—Jacob Sang, of Amsterdam—was almost exclusively done on imported English drinking glasses. English lead glass also seems to have been particularly favoured by the Dutch diamond-point engravers, whose work in this period was executed almost exclusively in stipple (*i.e.*, dotted engraving). The chief masters of this delicate art, in which the design seems no more than a bloom on the surface of the glass, were Frans Greenwood of Dordrecht, the originator of the style (Figure 223), and David Wolff of The Hague, whose work, if uninspired, is of high technical accomplishment.

Enamelling, the second decorative technique of foreign inspiration, began to be used on English glass in the mid-18th century. It embellished opaque white glass in imitation of china—a type of work usually associated with the name of Michael Edkins, a Bristol artist, but in fact done in many parts of the country. Perhaps the most original work in this medium was done on clear glass by members of the Beilby family of Newcastle upon Tyne during the 1760s and 1770s. Their rendering in usually blue-toned white enamel of ruins, trophies of arms, and rural pastimes, often framed in scrollwork of the utmost delicacy, is one of the best things in English Rococo glass. Gilding was also used at this time to decorate glasses, usually with simple designs of vines and grapes.

Figure 223: Glass goblet with diamond-point stipple engraving; signed "F. Greenwood fecit 1764." Holland. In the Museum für Kunst und Gewerbe, Hamburg. Height 28 cm.

By courtesy of Museum fur Kunst und Gewerbe Hamburg

These ornamental techniques, however, were of ephemeral growth in England. Far more significant than any of them, because more firmly rooted in the very nature of English glass, was the art of cutting. Although literary references to cut glass occur before 1720, the earliest known pieces can hardly be dated much before 1725. On them the cutting is mainly confined to brims and feet, which are scalloped or notched; or, on wineglasses to the thicker parts of the glass, such as the stem, which might be fluted or cut in an allover pattern of flat diamonds. Throughout the period from about 1745 to 1770, shallow cutting was the norm. Diamonds, hexagons, flutes, and scale pattern were combined with segmental lunate cuts (produced by holding the glass at an angle to the cutting wheel) and with triangular and diamond motifs in very low relief. All of these elements could be combined to produce designs of great complexity and richness. This period marked the golden age of English cutting.

Importance of cutting as a decorative technique

About 1770 a plainer style, employing mainly flutes, responded to the rising Neoclassical fashion in the other arts. The flutes were sometimes combined with diamonds in relief. When further taxes were imposed on glass in 1777 and 1781 and when in 1780 trade between England and Ireland was freed, it was this relief-diamond style that was taken up in Ireland by the glasshouses founded there. The Irish glassworkers could afford to be more lavish with their material and on this thicker glass increasingly deeply cut diamonds and other relief motifs could be produced. About the turn of the century the diamonds began to be reduced in size and to be incorporated into a diaper pattern covering whole areas, often alternating with fields of larger truncated diamonds, the surfaces of which were themselves diversified with cut crosshatching. Such designs were often combined with deeply cut horizontal grooves. These styles, which were subsequently followed

in England as well as in Ireland, finally led to a complete breaking up of the face of the glass into points and ridges, with increased prismatic effect but with a disastrous loss of surface quality, which is one of the peculiar beauties of glass. The prismatic brilliance was enhanced by the progressively greater purity and whiteness of the glass made during the second quarter of the 19th century. The temptation to cut ever more deeply and with greater complexity finally seduced the glassmakers into producing the "prickly monstrosities" of the Great Exhibition of 1851.

Throughout the 18th century there had been great admiration in Europe for English lead "crystal," and in the second half of it some of the European glasshouses were using lead oxide and had contrived to produce a comparable material. English cut glass was admired and exported, and the styles of cutting of the late 18th and early 19th centuries were much imitated abroad. (R.J.Ch.)

UNITED STATES

Glassmaking was apparently the first industry to be transplanted from Europe in the wake of the Spanish conquerors. As early as 1535 glass was being made at Puebla in Mexico, and in 1592 a glasshouse was located in the territory of the Río de la Plata in the town of Córdoba del Tucumán, Argentina. Broken glass, undoubtedly of European origin, was remelted at Córdoba and fashioned into various objects including thick, semitransparent flat glass.

The London Company of Virginia set up a glasshouse in Jamestown in 1608 for the manufacture of "glasses" and beads. A "tryal of glasse" was sent off to England before the winter of 1609, the "starving time" during which 440 of the colony's 500 inhabitants died. In 1621 the company tried again and, although the second attempt was more carefully planned, it too failed. Excavation of the site has revealed that glass was melted in considerable quantities though no evidence of glass bead manufacture has been found.

South Jersey-type glass. For more than a century after Jamestown, there was little American glass. The earliest successful glasshouse was begun in 1739 by Caspar Wistar in Salem County, New Jersey. The fact that his works produced only humble utilitarian vessels and windowpanes saved him from extermination by the "lords of trade." Wistar died in 1752, after which the factory was operated by his son Richard. It was offered for sale in 1780. Although few, if any, objects exist that can be assigned to the Wistar Glass Works with certainty, it is important as the cradle of the American glass known today as South Jersey type. That glass is the work of individual glassblowers using ordinary bottle or window glass to make objects of their own design. Applied glass and, occasionally, pattern molding were the only feasible means of decoration, and the resultant loopings and threadings are typical of European traditions. One decorative device, the lily pad, is of particular importance, as no European prototype is known. A hot mass of glass applied to the base of the bowl is pulled up around the sides in a series of projections in which the bowl appears to rest.

Wistar's glasshouse

Stiegel glass

The second great name in early American glass is Henry William Stiegel. Like Caspar Wistar, Stiegel at first was concerned with the manufacture of bottles and windowpanes, which he began in 1763 at his iron forge in Lancaster County, Pennsylvania, and continued in his new glasshouse at Manheim, also in Lancaster County, sometime after 1765. Encouraged by the patriotic adoption of the non-importation agreement, he ventured into the table-glass business, running many advertisements in which he favourably compared his wares with English imports. Later called the American Flint Glass Works, it failed in 1774 after adverse economic conditions, caused by both the approaching war and the colonial preference for imported tablewares.

Few pieces can be attributed with confidence to the Stiegel factories, and, like that of Wistar, his name survives as the founder of a tradition (Figure 224). Stiegel-type glass is characterized by the use of clear and artificially coloured glasses; by extrinsic decoration such as engraving, enamelling, and pattern molding; and, in general, by two distinct styles, one employing English and the other

German techniques and decorative devices. Certain mold-blown patterns, such as the diamond daisy and daisy in hexagon, are believed to have been originated at the Stiegel houses, no European prototypes having been identified.

Post-Revolutionary glassworks. Before the turn of the century, several other glassworks were founded, but few survived the Revolution. These houses were devoted largely to the manufacture of bottles and window glasses and, with the notable exception of the New Bremen Glassmanufactory, most of the offhand (*i.e.*, shaped by hand) pieces that can be tentatively assigned to them are of the South Jersey tradition. Three of these enterprises are of particular importance. First, the New Bremen (Maryland) Glassmanufactory, founded by John Frederick Amelung and Company, is of special interest as many of its presentation pieces are both signed and dated as well as being among the finest produced in the United States before

1800. Originally from Bremen, Germany, Amelung was persuaded to go to America for the express purpose of founding what he believed to be a much-needed industry. By 1785 his works offered green and white hollow ware for sale; by 1795 the glassworks themselves were offered for sale. One of the most famous pieces in the history of American glass is the Bremen Pokal (the German word for goblet), blown and engraved in 1788 (Figure 225) and sent back to Amelung's financiers in Bremen, probably the only return they ever received on their investment.

The second factory of importance, later known as the Olive Glass Works, Gloucester County, New Jersey, was completed in 1781 by former employees of the Wistar Glass Works, the Stanger brothers. In addition to the many fine South Jersey pieces attributed to this house, it is of interest because of its long history, eventually becoming part of the Owens Bottle Company, a forerunner of Owens-Illinois, Inc.

The Pitkin glassworks

The third notable venture begun before 1800 is the well-known works associated with the name Pitkin. Erected at East Hartford, Connecticut, near the Connecticut River in 1783, it was intended for the manufacture of window glass, but in 1788 it was converted to the manufacture of bottles and flasks. The factory thrived until 1830 and is best known for the half-post (*i.e.*, dipped twice up to the neck) ribbed flasks in natural browns, ambers, and greens. Today the word Pitkin denotes a type of flask and not a specific glassworks.

After the War of 1812. The few houses that survived the 1790s and the depression after the War of 1812 had multiplied to more than 90 by 1830. For convenience, the glassworks are divided into three geographical groups: New England, the Middle Atlantic, and the Midwest. Until that time, they had produced little more than simple imitations of European glasses, at best interesting and often very handsome combinations of various decorative devices and traditions. The big change occurred between 1830 and 1840 with the production of fine lead glass, the use of the full-size incised mold, and, finally, the pressing machine.

Bakewell's fine glass

The glasshouse known as Bakewell's was synonymous with the finest achievements of the revived industry. Originally established in 1808 in Pittsburgh, the first city to use coal for fuel in glassmaking, the company survived under several different firms until 1882. Glass cutting, introduced to Pittsburgh by William Peter Eichbaum, glass cutter to Louis XVI, was an important part of Bakewell's operation. In addition to being the first American company to supply the White House, serving President James Monroe in 1817, Bakewell's produced such specialties as lead-glass tumblers with "sulphides" (cameo insertions of white fireproof material in an envelope of glass) in the bases portraying the Marquis de Lafayette, Andrew Jackson, New York governor George Clinton, Benjamin Franklin, and George Washington. The company also held the first patent on mechanical pressing, granted in 1825 for a device to make knobs.

Fine lead glass in the New England area was first successfully made in the South Boston works of the Boston Crown Glass Company. Thomas Cains was making flint glass there in 1813. He left the firm in 1824 to found the Phoenix Glass Works in South Boston, which survived until 1870. One particular device usually associated with the Boston manufactories of this period is the guilloche, or chain, employed in the decoration of a large variety of tableware.

The New England Glass Company, founded in 1818 in Cambridge, Massachusetts, maintained the same high standards as Bakewell's, even to the point of making glass for President Monroe. This factory held the second patent on a device for mechanical pressing, granted in 1826, and produced quantities of pressed glass of all types before it was moved to Toledo, Ohio, in 1888. The New England Glass Company was also famous for its very fine freeblown and engraved glass. In addition, vessels were made there in the so-called blown three-mold technique, in which decorative designs adapted from cut-glass patterns of the period were impressed in the glass by blowing in molds hinged in two, three, or more sections. More than 400 different molds have been determined and grouped according to pattern under three primary headings: geometric, arch, and Baroque. By 1830 this type of production was being replaced by the much more efficient pressing machine.

The three-mold technique

Deming Jarves, one of the founders of the New England Glass Company, founded the Boston and Sandwich Glass Company in 1825. Because of his *Reminiscences of Glassmaking*, extensive advertisements, and thorough excavations of the factory site in Sandwich, Massachusetts, more is known about this particular factory than any other of the period. Consequently, "Sandwich" has become a generic term for pressed glass even though many other factories used identical machinery and, in some cases, identical molds. Jarves's first patent on a pressing device, the fifth to be granted, was received in 1828 after the Boston mold maker Hiram Dillaway entered his employ. Jarves founded the Mount Washington Glass Works in 1837 in New Bedford, Massachusetts, and the Cape Cod Glass Works in 1857.

Among the outstanding makers of fine lead glass in the middle Atlantic states were the Brooklyn Flint Glass Works of John L. Gilliland and Company and the Dorflinger Glass Works. Gilliland, a partner in the Bloomingdale Flint Glass Works, sold out in 1823 and founded his own works in Brooklyn, New York. In 1864 two members of the Houghton family acquired controlling interest, and in 1868 the works was moved by barge to Corning, New York, to form part of the now famous Corning Glass Works.

Historical flasks. Perhaps the most fascinating aspect of American glass is a series of pictorially molded bottles known as historical flasks, produced between 1815 and 1870. Some three hundred ninety-eight different surviving examples have been divided into the following groups: (1) Masonic; (2) emblems and designs related to economic life; (3) portraits of national heroes and designs associated with them and their deeds; and (4) portraits of presidential candidates, emblems and slogans of political campaigns. In the second group are a number of interesting designs encouraging the United States system of better internal transportation and high protective tariffs. Among the 16 celebrities portrayed in the third and fourth groups are Jenny Lind, the Swedish singer; Lajos Kossuth, the Hungarian patriot (Figure 226); Marquis de Lafayette, the French hero of the American Revolution; and the notorious Thomas W. Dyott, a patent-medicine vendor and bottle manufacturer. These containers were used also as propaganda during political campaigns. William Henry Harrison is pictured in this connection with other impedimenta relative to the "Log Cabin and Hard Cider" campaign of 1840.

The "lacy period" of pressed glass

The first 25 years of pressed glass, 1825 to 1850, are referred to by collectors as the "lacy period." A mile-

By courtesy of the Corning Museum of Glass, New York

stone within this brief span occurred in 1830 with the development of the cap ring, a device that ensured uniform thickness at the edge of each piece regardless of the amount of glass forced into the mold. Before this date most impressed designs were inspired by Anglo-Irish cut glass, often coupled with popular American devices such as a sheaf of wheat. Between 1830 and 1840 the objects were thinner and more lavishly decorated, often including elaborate motifs based on the classic and Gothic revivals. Because of the unpleasant surface left by the mold and in an effort to imitate the brilliance of cut glass, unstippled areas were filled in with overall lacelike patterns; hence the term "lacy." About 1840 economic conditions forced glassmakers to revert to cheaper molds and simpler geometric forms and to abandon the stippled patterns.

During this period the mechanical press became firmly established, and by mid-century glassmaking had become one of the United States' new mass-production industries.

(T.S.Bu.)

Mid-19th to 20th century

The modern history of glass can be said to begin in the middle of the 19th century with the great exhibitions and with the new self-consciousness in the decorative arts that they expressed. Glassware was being publicly discussed in art journals and collected in museums, and this new spirit of awareness led to a greatly increased exchange of ideas among the leading glass centres and to the borrowing of ideas from the past.

In some degree the established glass-producing centres were still concerned in the modern period with the styles of glassware for which they had achieved an earlier reputation. The English glasshouses continued their production of deeply cut crystal; engraved glass and to a lesser extent coloured and painted glass were given the greatest attention in central Europe; the Venetian glasshouses at Murano were the leading exponents of furnace-manipulated glass. But alongside these traditional methods of using and decorating glassware can be discerned the development of a renewed interest in the beauty of the material itself. Expressed in various ways, in the use of thick masses and in internal figuring and patterning, this interest has been the keynote of the most significant modern contributions to the art of glass.

Pressed glassware, which had been first made with great promise in the first half of the 19th century, was being widely made in the middle of the century, and later, as a cheap imitation of cut crystal. The decorative possibilities of the process continued, however, to be exploited in a variety of popular wares; and in the 20th century a series of new simple forms of pressed glassware appeared that had been expressly designed in relation to the characteristics of its manufacture.

GREAT BRITAIN

The Great Exhibition of 1851 was the culmination of a period of intense activity in the British glasshouses. The excise duty on glass had been removed in 1845, and the British glassmakers were determined not only to excel in their traditional deeply cut crystal but also to rival the Bohemians and the French in coloured, layered, and enamel-painted wares. Probably the most enterprising of the English glassmakers of the period was Benjamin Richardson, of Wordsley near Stourbridge; surviving pieces of this period from the Richardson firm include some admirable painted and engraved pieces as well as crystal wares deeply cut in bold patterns.

Probably in reaction against the banality of pressed-glass imitations of cutting, the most sophisticated work in crystal during the later 1850s through the 1870s was decorated by engraving, often carried out by immigrant Bohemian craftsmen.

The Venetian style of furnace-manipulated glass was also exerting a strong influence. It can be seen, for instance, in the development of the elaborate Victorian centrepieces in the 1860s and 1870s. In some degree the Venetian style was also an influence, alongside that of the Far East, in the fashioning of the fancy wares that were made in Great Britain—as it was in the United States and elsewhere—during the 1880s and 1890s. These wares were often given specific trade names and were mostly made in the English Midlands by firms such as Thomas Webb & Sons of Stourbridge and John Walsh Walsh of Birmingham.

A striking form of mid-Victorian virtuosity was the cameo glass produced by Stourbridge glassworkers. This work, inspired by the Portland vase, required a lengthy process of etching and carving, normally through an opaque-white-glass layer to leave a white carved design in relief on a dark-coloured glass body. The first important pieces, such as the "Pegasus vase" (Figure 227), were produced in the

1870s by John Northwood, and in the later part of the century the most distinguished cameo work was carried out by George Woodall.

The influence of the Arts and Crafts Movement was toward the use of plastic forms and furnace decoration, which the English art critic John Ruskin had advocated in *The Stones of Venice*. In 1859 Philip Webb designed for William Morris some simply formed tableware that was made at the London glassworks of James Powell & Sons. From about 1880 this glassworks was under the control of Harry J. Powell who, working until World War I, developed a simple, dignified style of handmade blown glass, which was subsequently continued in designs by Barnaby Powell, James Hogan, and others.

Influence of the Arts and Crafts Movement

During the 1930s and after World War II other firms produced work in which a restrained and distinctively modern approach was made to the cutting of faultless crystal glass. Notable designs were produced by Keith Murray for Stevens & Williams shortly before World War II and by David Queensberry (12th marquess of Queensberry) for Webb Corbett in the 1960s. Among the more distinguished glass engraving may be mentioned the diamond-point fantasies of Laurence Whistler and the work of John Hutton, made by a movable wheel held in the hand, such as his great screen in the new Coventry Cathedral. The appearance of new factories in the 1960s, concerned primarily with form and colour, widened the scope of British glass design; and at this time the glass-teaching schools

were especially significant as centres for original work by individual artists.

UNITED STATES

Importance of pressed glass

By the middle of the 19th century, American pressed glass was already a disturbing influence on the design of the finer wares. Its decoration was by that time mostly designed in imitation of cut glass, and the process of fire polishing was being used to give a surface almost as smooth as that of blown glass. During the succeeding decades pressed-glass designs became increasingly complicated. This tendency was accentuated in the soda-lime glass that William Leighton began to use for pressed work at Wheeling, West Virginia, in the 1860s, and that was later widely used in the western glasshouses for the cheapest coloured wares.

In general the finer wares of the early part of the period were similar to those of the Biedermeier and later styles of Europe. The New England Glass Company at Cambridge, Massachusetts, was employing many European craftsmen and was producing a wide variety of richly decorated layered and engraved wares. At the Boston and Sandwich Glass Company layered glass was extensively used for large kerosene lamps. The effect of the competition of pressed glass on cut-crystal work can be seen in the appearance of fine-line cuttings, and, during the period up to the Philadelphia Centennial Exposition of 1876, the most significant crystal work was decorated by engraving. Louis Vaupel and Henry S. Fillebrown were two notable engravers employed by the New England Glass Company from 1856 and 1860, respectively.

At the time of the Centennial Exposition, cut-crystal work began to revive, and by 1880 a considerable boom in its production had developed—a boom that was to continue throughout the 1880s and 1890s. New industrial methods contributed to the production of crystal glass of flawless quality and to its deep cutting with mathematical accuracy in elaborate designs. Among many others, a noteworthy producer of this type of glass in the 1890s and later was the Libbey Glass Company, the successor to the New England Glass Company. Later, in the early years of the 20th century, intaglio cutting in crystal became popular, and work in this expensive process was carried out in a number of cut-glass factories such as the T.G. Hawkes Glass Company at Corning, New York.

As in Great Britain and elsewhere, a great amount of glass was made in fancy forms and colours in the 1880s and 1890s. Although undisciplined and often tasteless, such glass nevertheless preserves perhaps more than any other the flavour of the period. These wares, often bearing specific names such as Pomona, Burmese, and Peachblow, were made by such firms as the New England Glass Company, the Mount Washington Glass Company at New Bedford, and the Hobbs, Brockunier Company at Wheeling, West Virginia.

Figure 228: Peacock vase, Favrile glass by Louis Comfort Tiffany. In The Metropolitan Museum of Art, New York. 35.9 × 29.2 cm.

Although belonging essentially to the category of the fancy glasses, the Favrile glass of Louis Comfort Tiffany (Figure 228) represented an altogether higher level of achievement both in its shapes and in the colouring and figuring of the glass. It was first shown to the public in 1893, and in pieces that were produced a few years later Tiffany achieved an outstanding expression in glassware of the Art Nouveau style. Much of his work was in a heavily lustred glass that was considerably admired abroad, especially in central Europe where it created a new fashion.

Tiffany's Favrile glass

Figure 229: "Moby Dick," Steuben crystal sculpture designed by Donald Pollard and Sidney Waugh, first piece made in 1959. Length 28.6 cm.

From the period of World War I onward, new forms of pressed glassware appeared in simple, satisfying designs appropriate to their purpose and the process of manufacture, such as the Pyrex ovenware shapes of the Corning Glass Works. The Steuben Glass Company of Corning was known for fancy glasses designed by Frederick Carder, until in 1933 the company was given a change of direction by Arthur Amory Houghton, Jr., who, with the help of John Monteith Gates and the sculptor and designer Sidney Waugh, aimed to produce glass with engraved decoration that would rank as fine art (Figure 229). Other noteworthy modern American work included simple designs in blown glass by the Blenko Glass Company of Milton, West Virginia, and enamel patterned bowls by the independent artist Maurice Heaton. The appearance in the United States of studio blown glass, produced by individual artists, was a development of international significance. It was initiated in the 1960s notably by Harvey Littleton and Dominick Labino and included work such as that produced personally by Joel P. Myers at the Blenko Glass Company.

CZECHOSLOVAKIA, AUSTRIA, AND GERMANY

In the middle of the 19th century the glasshouses of central Europe were producing a great variety of the layered and coloured wares that had become particularly associated with Bohemia in the preceding Biedermeier period (Figure 230). They were also producing a great amount of cut crystal glass in the deeply cut English style, and indeed work of this nature continued with little change throughout the modern period.

Revival of engraving

A revival of the indigenous art of engraving was initiated

Figure 230: Bohemian layered-glass vase, painted and gilt by Wilhelm Hoffmann, Prague and Vienna, *c.* 1850–60. In the Victoria and Albert Museum, London. Height 42 cm.

By courtesy of the Victoria and Albert Museum, London

by Ludwig Lobmeyr, who from 1864 was in control of the Viennese firm of J. and L. Lobmeyr. His first opportunity came at the Paris International Exhibition of 1867, and his reputation was firmly established at the Vienna International Exhibition of 1873. He commissioned designs for his glasses from the leading Viennese architects and painters of the time, and his work was carried out by the finest craftsmen in Bohemia and Austria.

The Art Nouveau style, which went under the name of Jugendstil in central Europe, made a deep impression on central European glassware. The work made around the turn of the century abounds in slender shapes and flowing organic motifs. Glasses designed by Karl Köpping in Berlin, with long, waving stems and tulip-like bowls, were perhaps the extreme instance of Art Nouveau style applied to glassware. In 1897 an exhibition of glass by Tiffany was shown at several of the museums in the area. Not only the forms of the Tiffany glasses but also their figured and heavily lustred material attracted great interest. Several factories started making a similar heavily lustred glass, including the firm of J. Lötz' Witwe of Klášterský Mlýn (Klostermühle), which won a *grand prix* at the Paris Exhibition of 1900 with this type of glassware.

From around 1900 onward a movement toward a modern purist approach to glass was largely fostered by the work of designers connected with the Vienna Kunstgewerbeschule (School of Industrial Art). Men such as Kolo Moser and Josef Hoffmann, who were also closely associated with the Vienna Werkstätte (Workshop), were designing glasses in simple rational forms. Much initiative in this movement was shown by the firms of E. Bakalowits Söhne of Vienna and J. Lötz' Witwe. The Czech architect Jan Kotěra was influential in the modern design of glass, and in the early years of World War I the Czech Artěl organization of artists and architects was concerned with the design of glass in a forward-looking Cubist manner.

Post-World War I glass

After World War I the outstanding figure in Czech glass art was Josef Drahoňovský, who was professor at the Prague School of Industrial Art. He was essentially a sculptor, and most of his glass designs were for sumptuously engraved glass of a monumental quality. His colleague in Prague, Jaroslav Horejc, designed for engraved work of a broadly similar character, some of it for the Lobmeyr firm of Vienna. The decades after World War II saw considerable activity in glass design. Notable artists in the 1960s were Stanislav Libenský, René Roubíček, Pavel Hlava, and Václav Cigler.

In Austria after World War I the Lobmeyr firm under the control of Stefan Rath produced many engraved and relief-carved pieces designed by artists such as Ena Rottenberg, Lotte Fink, and Vally Wieselthier. Lobmeyr also produced some of the best designs of Michael Powolny, who had his own workshop and had designed for the firm of J. Lötz' Witwe.

In Germany the outstanding engraver and glass carver of the period after World War I was Wilhelm von Eiff, a professor at the Stuttgart Kunstgewerbeschule. Bruno Mauder of the glass-teaching school at Zwiesel in Bavaria advocated the use of natural and appropriate glass forms. Some fine tablewares were produced, especially after mid-century, by designers such as Wilhelm Wagenfeld, Richard Süssmuth and Heinrich Löffelhardt. An interesting development was that of the Rosenthal firm, which used the Finnish designer Tapio Wirkkala and the Dane Bjørn Wiinblad to effect in each case matching glass and porcelain suites of the firm's own manufacture.

FRANCE

In France, as in central Europe and in England, the production of fine glassware in the middle of the 19th century was mainly divided between cut crystal and coloured wares. The "opalines," the semi-opaque white and coloured wares, often with elaborately painted and gilt decoration, were especially popular; and it was during these years that the French paperweights, containing coloured patterns, became internationally known and admired. The larger factories, particularly Baccarat and Saint-Louis, continued to participate in the international fashions of the rest of the century and beyond. But in France inventive genius manifested itself mainly in the work of individual artists and thereby a new spirit was introduced into the modern conception of glass.

In the late 1860s and 1870s three individual artists were experimenting in glasswork, and all of them were represented in the International Exhibition of 1878 in Paris. The first was Joseph Brocard, who was studying the enamelling of glass and whose main ambition was to reproduce medieval Syrian glass. The second was Eugène Rousseau, a commissioning dealer in ceramics who had turned to glasswork at the end of the 1860s and was at the height of his achievement in the years *c.* 1880. Typically his glasses were thick walled and translucid, often with interior crackling and shot with random streaks of colour. In 1885 he associated with E. Léveillé, who continued to work in a similar style after Rousseau's death in 1891. The third of the individual artists at the 1878 exhibition and the best known of them was Émile Gallé of Nancy, who had been experimenting in glasswork since about 1867. His earliest work was in clear glass, lightly tinted and decorated with enamel and engraving. But he soon developed the use of deeply coloured, almost opaque glasses in heavy masses, often layered in several thicknesses and carved or etched to form plant motifs. His work reflected the prevailing interest in Japanese art and with its frequently asymmetrical form contributed largely to the Art Nouveau of the end of the century. In this period much of Gallé's manner was reflected in the glassware produced on a more commercial basis by the firm of Daum Frères of Nancy.

Gallé glass

A number of French artists successfully explored the use of *pâte de verre* (powdered glass fired in a mold). The pioneer in its use was Henri Cros, who was working near the end of the 19th century. It was later the medium for important work by Albert Dammouse and François Décorchemont.

Among the later leaders of French glass art was René Lalique, who around the 1920s was producing his most typical work, which is characterized by relief decoration produced by blowing into molds or by pressing. He was a leading advocate of the use of glass in architecture and much of his work was in the form of lighting equipment and in details of interior decoration. The work of his contemporary, Maurice Marinot, was more in the tradition of Rousseau, with heavy, thick-walled vessels in strong forms often with boldly cut-away abstract decoration; and Henri Navarre in the 1930s was producing work of a similar monumental nature.

The most significant work of Jean Luce and Marcel Goupy, designers of glass and ceramics, was in the production of elegant tablewares. For a long period André Thuret made glasses in thick plastic forms; and Jean Sala worked in bubbled glass. The firm of Daum was distinguished, after World War II, by its thick clear glass vessels manipulated into flowing shapes to designs by Michel Daum.

THE SCANDINAVIAN COUNTRIES

Development of modern Swedish glass

Up to the time of World War I the Swedish glass industry produced little original work. The sudden development of modern Swedish glass in the 1920s was attributable mainly to the initiative of the Swedish Arts and Crafts Society that resulted in the employment of the painters Simon Gate and Edward Hald by Orrefors glassworks and Edvin Ollers by Kosta glassworks, both in the glass-producing area of Småland in southern Sweden. The first results were exhibited in Stockholm in 1917 and consisted of handblown, undecorated tablewares, together with the luxury "Graal" glass with internal stained decoration, which had been rapidly developed under Gate's inspiration at Orrefors. It was, however, engraved glasswork, chiefly that designed by Gate and Hald at Orrefors, on which the reputation of Swedish glass was established in the 1920s and particularly at the Paris International Exhibition of Decorative Arts in 1925.

In the 1930s came a change of direction. The Swedish factories began to take less interest in engraving and followed the initiative of the French artists in making thick tinted and figured glasses. In this mode they found their greatest success—attributed largely to their having achieved a system of intimate association between the artists and the glassmaker craftsmen.

At Orrefors additional artists were added to the establishment from 1929 onward, including Vicke Lindstrand, Sven Palmqvist, Nils Landberg, Edvin Öhrström, John Selbing, and Ingeborg Lundin. Each of them worked in an individual style, and in addition to decorative pieces many of them designed tablewares for the subsidiary Sandvik factory. At Kosta important work was produced by Elis Bergh and later by Lindstrand. Gerda Strömberg designed for both Eda glassworks and for Strömbergshyttan. In the 1960s many new methods of forming and decorating glass were explored by young designers; and an element of the current Pop art was discernible, such as in the work of Gunnar Cyrén at Orrefors.

In Denmark the Holmegaard glassworks and in Norway the Hadeland glassworks both followed in some respects the example of Swedish glass. At Holmegaard the movement began in the late 1920s with the appointment as art director of Jacob E. Bang, whose designs included an amount of striking engraved work, and was continued in the clean forms of his successor, Per Lütken. At Hadeland some distinctive glass was designed by a number of artists including Sverre Pettersen, Willy Johansson, and Arne Jon Jutrem.

Modern Finnish design

In Finland original modern work of great significance has been carried out. Following the example of the Swedish factories, the artist Henry Ericsson was appointed designer at the Riihimäki glassworks in the late 1920s, and Göran Hongell was employed in a similar capacity at the Karhula glassworks in the 1930s. At this time the well-known Finnish artists Arttu Brummer and Alvar Aalto were also concerned in glass design. Shortly after World War I the influential designer Gunnel Nyman was producing glasses freely blown in thick masses to form asymmetrical shapes. Other important designers were Tapio Wirkkala and Timo Sarpaneva working for the Iittala glassworks (Figure 231), Kaj Franck for the Nuutajärvi glassworks (trading as Wärtsilä-Notsjö), and Helena Tynell and Nanny Still for Riihimäki. In the 1960s Timo Sarpaneva struck a new note with his sculptures formed from the charred inner surface of wooden molds, while Oiva Toikka designed for Wärtsilä-Notsjö objects of a markedly Pop art nature.

BELGIUM AND THE NETHERLANDS

In Belgium the Val-Saint-Lambert factory was an important producer of heavily cut crystal throughout the period. It is also associated with layered work and was particularly prominent with original work of this nature around 1900. Later Charles Graffart designed for it wares made in a variety of techniques, some of them with engraved decoration.

The Dutch glassworks at Leerdam played an important part in the modern movement and followed a line of development distinct from that of the Scandinavian factories. In 1915 the decision was made to invite designs from artists, and by the early 1920s excellent simple tablewares were being made to designs by the architects K.P.C. de Bazel and H.P. Berlage and by the decorative artist C. de Lorm. From the early 1920s onward individually designed pieces called Unica were made; some of the earlier examples were by Chris Lebeau, but most were produced by Andries D. Copier. Later decorative work included designs by Floris Meydam and Willem Heesen.

ITALY

Variations of traditional Venetion glass

By the middle of the 19th century, Italian glassmaking had partly revived. In the 1860s the Museo Vetrario was founded at Murano (Venice), and Antonio Salviati began to produce the glasses that attracted much attention at the Paris Exhibition of 1867. These were variations of the traditional Venetian style with elaborate furnace decoration, and the production of glasses of this nature continued at Murano throughout the remainder of the 19th century and beyond.

The 1920s saw the development of a more conscious spirit of artistry in Italian glasswork. Paolo Venini was concerned in producing simple elegant glasses designed by the decorative artist Vittorio Zecchin; and G. Balsamo Stella and his Swedish wife Anna were producing engraved work. In later years, both before and after World War II, much research was done in new methods of colouring and figuring glass; the results were seen in the glasses designed by Ercole Barovier for the firm of Barovier & Toso and in those designed by Giulio Radi for the firm Arte Vetraria Muranese.

From the Venini firm, presided over by Paolo Venini until his death in 1959, came many interesting innovations, such as the colourful glasses designed by Carlo Scarpa and by Fulvio Bianconi and an interesting series by the Finn Tapio Wirkkala. For the firm of Vistosi some striking modern glasses were designed by artists such as Peter Pelzel and Alessandro Pianon. Some of the work, such as a series of vases designed by Flavio Poli for Seguso Vetri d'Arte, showed some influence from the thick-glass techniques of the north, but the modern Italian glass mostly retained a distinctly Venetian, volatile character. An experiment of interest was the production of a series of glass

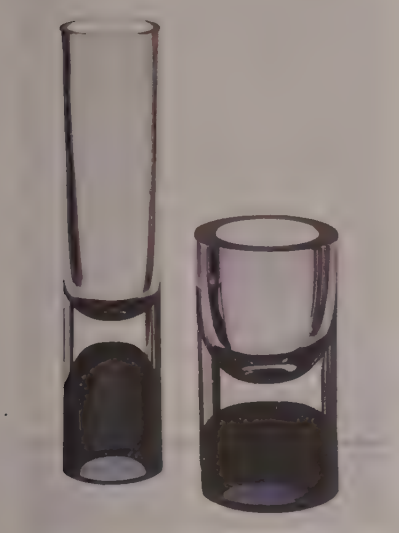

Figure 231: Double-cased glass vases designed by Timo Sarpaneva, Iittala glassworks, Finland, 1957. In Die Neue Sammlung, Munich. Height (left) 30 cm., (right) 17.5 cm.

sculptures from sketches and models commissioned by the dealer Egidio Constantini from internationally prominent painters and other artists. (Hu.Wa.)

Chinese glass

Glass has never been truly at home in China. Records suggest that it was brought there from the West as early as the 3rd century, but finds of small glass objects of typical Chinese shapes dating from as early as the Han dynasty (206 BC–AD 220) suggest that, even if the material was brought from the West, it could be worked on the spot to conform to Chinese usage. It was no doubt regarded as a cheap substitute for jade. The Chinese themselves do not claim to have made glass before the 5th century, and even then it is doubtful if they knew more than how to make beads and other similar small objects. The vessels of glass occasionally found in burials of the T'ang (618–907) and later dynasties, although perhaps locally made, are more likely imports. Of the extant glass vessels typically Chinese in form, none can be shown to be of a date earlier than the reign of the K'ang-hsi emperor (1661–1722), and there is every likelihood that glassmaking was in fact introduced in this period when, through the Jesuits, China became vividly aware of Western culture. To this period probably belongs a series of bowls and vases of which the blown character is manifest. They are often of a deteriorated material that appears to suffer from the same defects as European glass of the same epoch.

During the reigns of the Yung-cheng (1722–35) and Ch'ien-lung (1735–96) emperors, the emphasis on blown forms is subordinated to the desire to make glass a surrogate for natural stones. Although the colours used are often not such as are found in nature, the glass is handled as though it were jade, the foot in particular being fashioned as though cut from stone. This lapidary treatment is further emphasized in the cased glass bottles cut on the wheel in such a way that the design stands in one or more colours on a ground of a contrasting tone (Figure 232). (R.J.Ch.)

BIBLIOGRAPHY

Interior design. *General works:* ARNOLD FRIEDMANN, JOHN F. PILE, and FORREST WILSON, *Interior Design: An Introduction to Architectural Interiors* (1970), an introduction to the field of interior architecture written for students of design; SHERRILL WHITON, *Elements of Interior Design and Decoration*, 3rd ed. (1963), a scholarly text; RAY and SARAH FAULKNER, *Inside Today's Home*, 3rd ed. (1968), a thorough and well-illustrated book on the interior design of homes; DIANA ROWNTREE, *Interior Design* (1964), a brief and personal view of interior design written primarily for British readers; EDGAR KAUFMAN, *What Is Modern Interior Design?* (1953, reprinted 1969), a very brief but perceptive treatise. A later monograph on home decorating is MARY GILLIAT, *The Decorating Book* (1981), with special photography by Michael Dunne.

Special types of interiors: MICHAEL SAPHIER, *Office Planning and Design* (1968), a clear overview of the field of business and office interiors; BETTY ALSWANG and AMBUR HIKEN, *The Personal House* (1961), a photographic collection of very personal interiors primarily designed by the artist-occupants, rather than professional interior designers. The photographs and comments contained in the following works make them significant sources for the study and understanding of special interiors: WILLIAM WILSON ATKIN and JOAN ADLER, *Interiors Book of Restaurants* (1960); HENRY END, *Interiors Book of Hotels and Motor Hotels* (1963); JOHN F. PILE, *Interiors Second Book of Offices* (1969); MORRIS KETCHUM, *Shops and Stores*, rev. ed. (1957); GEORGE NELSON (ed.), *Living Spaces* (1952); MARY GILLIATT AND MICHAEL BOYS, *English Style in Interior Decoration* (1967).

Special subjects: JOHANNES ITTEN, *Kunst der Farbe* (1961; Eng. trans., *The Art of Color*, 1961); FABER BIRREN, *Color for Interiors, Historical and Modern* (1963); LESLIE LARSON, *Lighting and Its Design* (1964); JOHN F. PILE (ed.), *Drawings of Architectural Interiors* (1967); MARIO G. SALVADORI and ROBERT HELLER, *Structure in Architecture* (1963), a very readable introduction to structural principles understandable to laymen, but written on a very professional level; MARIO DAL FABBRO, *Modern Furniture*, 2nd ed. (1958). EDWARD LUCIE-SMITH, *The Story of Craft: The Craftsman's Role in Society* (1981), explores the unifying and the distinctive features of craft and fine arts.

Historical developments: GEORGE SAVAGE, *A Concise History of Interior Decoration* (1966), is the only English-language work that summarizes the history of the subject. Information about the earliest furniture may be found in HOLLIS S. BAKER, *Furniture in the Ancient World* (1966); and the *Natural History* (various editions) of PLINY THE ELDER, which contains much information in the final volumes on the Roman scene. Books about the Middle Ages are not numerous, but the *Guide to the Early Christian and Byzantine Antiquities* of the British Museum (1921), is a useful work. There are many books dealing with various aspects of the Renaissance, such as PETER and LINDA MURRAY, *The Art of the Renaissance* (1963); FRIDA SCHOTTMULLER, *Furniture and Interior Decoration of the Italian Renaissance* (1921); PIERRE DU COLOMBIER, *Le Style Henri IV–Louis XIII* (1941); GERMAIN BAZIN, *Classique, baroque et rococo* (1964; Eng. trans., *Baroque and Rococo*, 1964); and VICTOR TAPIE, *Baroque et classicisme* (1957; Eng. trans., *The Age of Grandeur*, 1960). PIERRE VERLET, *Le Mobilier royal français* (1945; Eng. trans., *French Royal Furniture*, 1963) and *Les Meubles français du XVIII siecle* (1956; Eng. trans., *French Furniture and Interior Decoration*, 1967), are important works by a great authority dealing with 18th-century developments. GEORGE SAVAGE, *French Decorative Art, 1638–1793* (1969), discusses most of the objects in general use for interior decoration. FISKE KIMBALL, *The Creation of the Rococo* (1943), is an important examination of the sources of this style; TERISIO PIGNATTI, *Il Rococo* (1967; Eng. trans., *The Age of Rococo* 1967; Eng. trans., *The Age of Rococo*, 1969), is a scholarly picture-book based on an exhibition so titled. ADRIEN FAUCHIER-MAGNAN, *Les Petites Cours d'Allemagne au XVIII Siecle* (1947; Eng. trans., *Small German Courts in the Eighteenth Century*, 1958), is valuable for information about the pervasion of French art and culture. The Wallace Collection (London) catalog of *Furniture* by F.J.B. WATSON (1956), and the catalog of *Sculpture* by JAMES G. MANN (1931), are scholarly works essential to the study of their subject; see also F.J.B. WATSON, *Louis XVI Furniture* (1960).

On English decoration the works of MARGARET JOURDAIN: *English Decoration and Furniture of the Early Renaissance* (1924), *Regency Furniture, 1795–1820* (1934), and *The Work of William Kent* (1948), are all worth consulting. PERCY MACQUOID and RALPH EDWARDS, *The Dictionary of English Furniture from the Middle Ages to the Georgian Period*, 2nd ed. rev., 3 vol. (1954), is a scholarly and important work. THOMAS A. STRANGE, *English Furniture, Decoration, Woodwork, and Allied Arts* (1900; reprinted 1950), reproduces many pages from 18th-century English design books, including Chippendale's *Director;* and HUGH HONOUR, *Neo-Classicism* (1968), discusses the style in its international implications, as well as dealing with that of the brothers Adam. SUSAN LASDUN, *Victorians at Home* (1981), discusses domestic interior in the period from 1820 to 1900.

For the Gothic revival there is no better source than SIR KENNETH CLARK, *The Gothic Revival* (1928, reprinted 1970). J. MORDAUNT CROOK, *William Burges and the High Victorian Dream* (1981), is a study of the life of a protagonist of the Gothic revival style in design. JOSEPH DOWNS, *American Furniture* (1952), is a standard work. GEORGE SAVAGE, *The Dictionary of Antiques* (1970), discusses former objects of interior decoration and their style from the Renaissance onwards. Art Nouveau has been the subject of a number of books in recent years. Among the best are MARIO AMAYA, *Art nouveau* (1966); MARTON BATTERSEY, *The World of Art Nouveau* (1968); and STEPHEN TSCHODI MADSEN, *Source of Art Nouveau* (1956).

There are no works discussing Oriental interior decoration only, and information must, for the most part, be gleaned from books discussing specific types of objects, such as painting, porcelain, furniture, and bronze. By far the best source is *Chinese Art*, 4 vol. (1960–65), an international symposium by several well-known Orientalists that discusses almost everything of importance to the subject. A useful general survey is LEIGH ASHTON (ed.), *Chinese Art*, by several well-known authorities (1935), which summarizes in one volume the salient facts about works in many differing materials. For Japanese art, MARCUS B. HUISH, *Japan and Its Art* (1889), is an excellent general work, but few books that can be recommended for the present purpose have been published in English.

On Islāmic art, an excellent work is DAVID TALBOT RICE, *Islamic Art* (1965); a more detailed survey is MAURICE S. DIMAND, *A Handbook of Muhammadan Art*, 3rd ed. rev. (1958). A.U. POPE and PHYLLIS ACKERMAN, *A Survey of Persian Art from Prehistoric Times to the Present*, 14 vol. (1938–67), should be consulted for this aspect. FRANZ BOAS, *Primitive Art*, new ed. (1955), discusses the principles behind the decoration of a wide variety of art of this kind, with special attention to the North Pacific Coast of North America. ERIC LARRABEE and MASSIMO VIGNELLI, *Knoll Design* (1981), is a history of modern commercial interior design.

Furniture and accessory furnishings. OLE HANSCHER, *Möbelkunsten* (1966; Eng. trans., *The Art of Furniture*, 1967), chronological survey of the art of furniture (with illustrations). GEORGE NAKASHIMA, *The Soul of a Tree: A Woodworker's Reflections* (1981), is an inspirational commentary of a designer and crafter on the art of furniture making.

Near East and classical antiquity: A. LUCAS, *Ancient Egyptian Materials and Industries*, 3rd ed. (1948), indispensable; HOWARD CARTER and A.C. MACE, *The Tomb of Thut-Ankh-Amen*, 3 vol. (1923–27); GISELA H. RICHTER, *The Furniture of the Greeks, Etruscans and Romans* (1966), the standard reference work in this area.

Middle Ages: VIOLLET-LE-DUC, *Dictionnaire raisonné bilier français de l'epoque carlovingienne a la Renaissance*, 6 vol. (1858–75), still an authoritative work.

Renaissance and later: (*Italy*): GEORGE LELAND HUNTER *Italian Furniture and Interiors*, 2 vol. (1918), mostly illustrations; WILLIAM M. ODOM, *A History of Italian Furniture from the 4th to the Early 19th Centuries*, 2 vol. (1918–19). (*Spain*): ARTHUR BYNE and MILDRED STAPLEY, *Spanish Interiors and Furniture* (1921), profusely illustrated with scale drawings and photographs. (*Germany*): HEINRICH KREISEL, *Die Kunst des deutschen Möbels*, 2 vol. (1968–70), thorough, illustrated history of German furniture. (*France*): PIERRE VERLET, *Le Mobilier royal français*, 2 vol. (1945–55); *Les Meubles français du XVII^e siecle*, 2 vol. (1956), a learned treatise on French furniture. (*England and the colonies*): PERCY MACQUOED and RALPH EDWARDS, *The Dictionary of English Furniture from the Middle Ages to the Late Georgian Period*, 2nd ed., 3 vol. (1954), documented survey of English and American furniture; RALPH FASTENEDGE, *English Furniture Styles from 1500 to 1830* (1962), an excellent elementary introduction to the study of English furniture; ANTHONY COLERIDGE, *Chippendale Furniture* (1968), illustrated study of Chippendale and his contemporaries; CLIFFORD MUSGRAVE, *Adam and Hepplewhite and Other NeoClassical Furniture* (1966), written by one of the best informed students of the Neoclassical English style of furniture; CHARLES F. MONTGOMERY, *American Furniture* (1966), a survey of Federal period furniture. See also BERRY B. TRACY, *The Federal Furniture and Decorative Arts at Boscobel* (1981); CHARLES SANTORE, *The Windsor Style in America* (1981); JOHN T. KIRK, *American Furniture and the British Tradition to 1830* (1983).

19th century and modern: E.D. and F. ANDREWS, *Shaker Furniture: The Craftsmanship of an American Communal Sect* (1937); R.V. SYMONDS and B.B. WHINERAY, *Victorian Furniture* (1962), with many illustrations; SERGE GRANDJEAN, *Empire Furniture, 1800 to 1825* (1966); MIKOLAUS PEVSNER, *Pioneers of Modern Design from William Morris to Walter Gropius* (1960); JEAN CASSOU, EMILE LANGUE, and NIKOLAUS PEVSNER, *Les Sources du vingtieme siecle* (1961); JOHN F. PILE, *Modern Furniture* (1979); JONATHAN L. FAIRBANKS and ELIZABETH BIDWELL BATES, *American Furniture, 1620 to the Present* (1981); DAVID A. HANKS, *Innovative Furniture in America from 1800 to the Present* (1981).

Rugs and carpets. For further study in this area the following summaries are recommended: FRIEDRICH SARRE and HERMANN TRENKWALD, *Altorientalische Teppiche*, 2 vol. (1926–28; Eng. trans., *Old Oriental Carpets*, 2 vol., 1926–29), excellent large plates with exact description and technical analysis of masterpieces of Oriental rugs and carpets, including a comprehensive bibliography; KURT ERDMANN, *Der orientalische Knüpfteppich*, 3rd ed. (1965; Eng. trans., *Oriental Carpets*, 2nd ed., 1962), an important discussion of Oriental rugs and carpets with regard to artistic development—contains a comprehensive bibliography for all areas of the Oriental carpet, including newspaper and journal essays, and museum and auction catalogs, arranged according to subject areas; and *Siebenhundert Jahre Orientteppich* (1966; Eng. trans., *Seven Hundred Years of Oriental Carpets*, (1970), a posthumous collection of the author's articles, presenting material not found in his earlier works; WILHELM VON BODE and ERNST KUHNEL, *Vorderasiatische Knüpfteppiche aus alter Zeit*, 4th ed. (1955; Eng. trans., *Antique Rugs from the Near East*, 4th rev. ed. 1970), a handbook on the scientific study of rugs and carpets; ALBERT F. KENDRICK and C.E.C. TATTERSALL, *Handwoven Carpets, Oriental and European*, 2 vol. (1922, reprinted 1973), a monographic treatment of the individual types, including products after 1800; ARTHUR V. POPE and PHYLLIS ACKERMAN, *The Art of Carpet Making in a Survey of Persian Art from Prehistoric Times to the Present*, 7 vol. (1938–39), the most comprehensive study of the art of carpet making in Persia, richly illustrated; CORNELIA B. FARADAY, *European and American Carpets and Rugs* (1929), a comprehensive study of European and American carpet production, including native arts and machine-made carpets (very richly illustrated but without bibliography); C.E.C. TATTERSALL, *A History of British Carpets*, rev. ed. (1966), an extensive study of carpet production in England, including machine-made carpets; M.J. MAJORCAS, *English Needlework Carpets, 16th–19th Centuries* (1963), a richly illustrated treatise; MADELEINE JARRY, *Manufacture nationale de la Savonnerie* (Eng. trans., *The Carpets of the Manufacture de la Savonnerie* 1966) and *The Carpets of Aubusson* (1969), two studies of French floor coverings, with ample illustrations and VALERIE JUSTIN *Flat-woven Rugs of the World: Kilim, Soumak, and Brocading* (1980). See also P.R.J. FORD, *The Oriental Carpet: A History and Guide to Traditional Motifs, Patterns, and Symbols* (1981); and GIOVANNI CURATOLA, *The Simon and Schuster Book of Oriental Carpets* (1982).

Tapestry. W.G. THOMSON, *A History of Tapestry from the Earliest Times to the Present Day*, 3rd ed. rev. and ed. by F.P. THOMSON and E.S. THOMSON (1973), a standard work on the history of tapestry, which has been updated by F.P. THOMSON, *Tapestry: Mirror of History* (1980); M.J. GUIFFREY, E. MUNTZ, and A. PINCHART, *Histoire generale de la tapisserie*, 3 vol. (1978–85), French tapestries discussed by Guiffrey, Italian tapestries by Muntz, Flemish tapestries by Pinchart; M. FENAILLE, *État general des tapisseries de la manufacture des Gobelins depuis son origine jusqu'a nos jours, 1600–1900*, 6 vol. (1903–23), a work of primary importance, presenting a detailed history of the Gobelins factory; J. BADIN, *La Manufacture de tapisseries de Beauvais, depuis ses origines jusqu'a nos jours* (1909), a basic reference for the history of tapestry production at the Beauvais factory; *Wandteppiche*, 6 vol. (1923–34; Eng. trans. of pt. 1, *Tapestries of the Lowlands*, 1924), a general worldwide treatment of tapestry, with numerous black and white illustrations, although many of the European medieval attributions have been questioned or rejected; G.L. HUNTER, *The Practical Book of Tapestries* (1925), precise and useful descriptions, with numerous reproductions; C.G. JANNEAU, *Évolution de la tapisserie* (1947), illustrations and technical information on collections of European tapestries, some of which have been subsequently disbanded with works relocated; D. HEINZ, *Europäische Wandteppiche*, vol. 1, *Von den Anfängen der Bildwirkerei bis zum Ende des 16. Jahrhunderts* (1963), a thorough treatment of tapestry up to the end of the 16th century, with a typological index, an extensive bibliography, and numerous illustrations; R.A. WEIGERT, *La Tapisserie et le tapis en France* (1964), a scholarly discussion of the history of French tapestry; P. VERLET *et al.*, *La Tapisserie: histoire et technique du 14^e au 20^e siecle* (1977; Eng. trans., *The Book of Tapestry: History and Technique*, 1978), a well-illustrated volume on Western tapestry from the Middle Ages to the 20th century; MADELEINE JARRY, *La Tapisserie des origines a nos jours* (1968; Eng. trans., *World Tapestry*, 1969), a well-documented study of tapestry throughout the world, including an extensive bibliography and many black and white and colour illustrations, and *La Tapisserie: art du 20^e siecle* (1974), a study of the worldwide renascence of tapestry during the 20th century; V. FOUGRE, *Tapisseries de notre temps* (1969), a brief study of contemporary French tapestry, with an index of tapestry artists and illustrated with black and white and colour reproductions; R.A. D'HULST, *Flemish Tapestries* (1967), an elaborate study of Flemish tapestry from the Middle Ages to the Baroque periods, with many colour illustrations; R. KAUFMANN, *The New American Tapestry* (1968), a well-illustrated text dealing with technique as well as with the works of leading American tapestry designers and weavers; G. SUTHERLAND, *Coventry Tapestry* (1964), an interesting account of the design, weaving, and installation of Sutherland's tapestry for Coventry cathedral; M.B. FREEMAN, *The Unicorn Tapestries* (1976), a detailed and well-illustrated history of these tapestries, which are housed at the Cloisters, a branch of the Metropolitan

Museum of Art, New York City; P. ACKERMAN, *Tapestry: The Mirror of Civilization* (1933, reprinted 1970), one of the classic works in English dealing with the historical development of European tapestry. LAYA BROSTOFF, *Weaving a Tapestry* (1982), is a brief overview with bibliography.

Collection catalogs: Important illustrated catalogs of tapestry collections include: A.S. CAVALLO, *Tapestries of Europe and Colonial Peru in the Museum of Fine Arts, Boston,* 2 vol. (1967); D. DU BON, *Tapestries from the Samuel H. Kress Collection at the Philadelphia Museum of Art* (1964); H.C. MARILLIER, *The Tapestries at Hampton Court Palace, London,* 2nd ed. (1962), and with A.J. WACE, *Marlborough Tapestries at Blenheim Palace* (1968); N.Y. BIRYUKOVA, *The Leningrad Hermitage Gothic and Renaissance Tapestries* (1966); M. CRICK KUNTZIGER, *Musees royaux d'Art et d'Histoire: Catalogues des tapisseries* (1956); A.M. ERKELENS, *Wandtapijten I. Late Goteik en vroege Renaissance, Rijksmuseum, Amsterdam* (1962); and A.F. KENDRICK, *Catalogue of Tapestries at the Victoria and Albert Museum* (1924). Tapestries of the second half of the 20th century are shown in numerous exhibition catalogs, such as ERIKA SELLMAN-BÜSCHING, *Tapisserien 1970 bis 1981* (1981); F. VIALET, *Tapisseries contemporaines d'Aubusson* (1981); *Swiss Tapestries, Artists of Today* (1981).

Floral decorations. LIBERTY HYDE BAILEY and ETHEL ZOE BAILEY (comps.), *Hortus Second: A Concise Dictionary of Gardening, General Horticulture and Cultivated Plants in North America* (1941), basic for nomenclature; VICTOR LORET, *La Flore pharaonique d'apres les documents hieroglyphiques et les specimens decouverts dans les tombes,* 2nd ed. (1892), includes information concerning wreaths and garlands; CHARLES VICTOR DAREMBERG and E. SAGLIO, *Dictionnaire des antiquites Grecques et Romaines d'apres les textes et les monuments,* vol. I, pt. 2 (1877), lists flowers grown and ornamental uses (under "Corona" and "Coronarius et Coronaria"); JOHN GERARD, *The Herball* (1597), descriptions and contemporary wood engravings of English garden flowers; JOHN PARKINSON, *Paradisi in Sole Paradisus Terrestris* (1629), descriptions and usage of flowers in 17th-century England; P. GIOVANNI BATTISTA FERRARI, *Flora ouero cultura di fiori* (1633), on the culture and care of cut flowers, including how to preserve, arrange, and ship them, with interesting illustrations; PHILIP MILLER, *The Gardeners Dictionary,* 2 vol. (1735), an important and popular 18th-century work, with full descriptions of garden flowers and illustrations; HELEN GERE CRUICKSHANN (ed.), *John and William Bartram's America* (1957), contains information about new plant discoveries and exchanges of garden material between America and England in the 18th century; *Godey's Lady's Book* (1830–98), almost monthly advice in the editorial pages about gardening or arranging flowers; J. RAMSBOTTOM, *A Book of Roses* (1939), information about old-fashioned roses; RALPH G. WARNER, *Dutch and Flemish Flower and Fruit Painters of the 17th and 18th Centuries* (1928), profusely illustrated; JULIA S. BERRALL, *A History of Flower Arrangement,* rev. ed. (1968), on all styles and periods, including original source lists of plant materials and many illustrations; MARGARET FAIRBANKS MARCUS, *Period Flower Arrangement* (1952), emphasis on art; JOSIAH CONDER, *The Theory of Japanese Flower Arrangements* (1935), reprint of an original paper read by the author in 1889 to the Asiatic Society of Japan, to which have been added 36 colour plates of Ikenobō and *moribana* arrangements; ALFRED KOEHN, *The Art of Japanese Flower Arrangement (Ikebana): A Handbook for Beginners* (1934), with actual photographs instead of paintings; DONALD RICHIE and MEREDITH WEATHERBY (eds.), *The Masters' Book of Japanese Flower Arrangement: With Lessons by the Masters of Japan's Three Foremost Schools: Sen'ei Ikenobo, Houn Ohara, Sofu Teshigahara* (1966), contains an excellent historic section illustrated from the arts and photographs in colour and black and white contemporary expressions; SHOZO SOTO, *The Art of Arranging Flowers* (1966), on all aspects of Japanese flower arranging, with excellent colour and black-and-white illustrations. Later works include GERTRUDE JEKYLL, *Flower Decoration in the House* (1982), and *Colour Schemes for the Flower Garden,* 8th ed. (1982); EMMA WOOD and JANE MERER, *Flower Crafts* (1982); MARIAN AARONSON, *Flowers in the Modern Manner* (1981); TOKUJI FURUTA, *Interior Landscaping* (1983); INTERIOR PLANTSCAPE ASSOCIATION (U.S.), *Manual of Practice* (1980); MARY ADAMS, *Natural Flower Arranging* (1981); EDITH BLACK, *Modern Flower Arranging* (1982).

Pottery. Books on pottery are fairly numerous, but of those that have been written in recent years for the popular market many are not always reliable and much information is duplicated among them. The following titles may be regarded as standard or major works.

General works: Two good introductory surveys are GEORGE SAVAGE, *Pottery Through the Ages* (1963) and *Porcelain Through the Ages,* 2nd ed. (1963). ROBERT J. CHARLESTON (ed.), *World Ceramics* (1968), is a lavishly illustrated history of ceramics written by many noted specialists in Europe and the United States. Highly recommended is W.B. HONEY, *European Ceramic Art, from the End of the Middle Ages to about 1815,* 2nd ed., 2 vol. (1963), which has a comprehensive list of marks and an excellent bibliography. Also useful is EMIL HANNOVER, *Keramisk Haandbag,* 2 vol. (1919–24; Eng. trans., *Pottery and Porcelain,* 3 vol., 1925); and WARREN COK, *The Book of Pottery and Porcelain* (1944). GEORGE SAVAGE, *The Dictionary of Antiques* (1970), includes information about continental wares on a less comprehensive scale, but its extensive bibliography has been brought up to date. It also differentiates between works in print and those available only in libraries or secondhand. For the technical side of pottery, see BERNARD LEACH, *A Potter's Book* (1940); W.B. HONEY, *The Art of the Potter* (1946); and PAUL RADO, *An Introduction to the Technology of Pottery* (1969). Factory marks are discussed and listed in W.B. HONEY and JOHN P. CUSHION, *Handbook of Pottery and Porcelain Marks,* 3rd rev. ed. (1965); Cushion has also published separate handbooks on *English Ceramic Marks and Those of Wales, Scotland, and Ireland* (1959), on *German Ceramic Marks and Those of Other Central European Countries* (1961), and on *French and Italian Ceramic Marks* (1965). GEOFFREY GOODEN, *Encyclopaedia of British Pottery and Porcelain Marks* (1964), is another recommended source. WILLIAM CHAFFERS, *Marks and Monograms on Pottery and Porcelain,* 14th ed. (1931), formerly the standard work, has now been superseded and is sometimes inaccurate. More specialized is ARTHUR BEHSE, *Deutsche Fayencemarken–Brevier* (1955), which should be consulted for German wares. Ceramic terms are defined by GEORGE SAVAGE and H. NEWMAN in the *Illustrated Dictionary of Ceramic Terms* (1973). See also ROBERT FOURNIER, *Illustrated Dictionary of Pottery Form* (1981).

Ancient Near East and Egypt: Books dealing specifically with the pottery of this area and period are scarce. See WALTER ANDRAE (ed.), *Coloured Ceramics from Assur* (1925); and HENRY WALLES, *Egyptian Ceramic Art* (1898). More information will be found in books dealing with the arts of the ancient Near East and Egypt.

Ancient Aegean, Greece, and Italy: Works on ancient pottery from these regions are fairly numerous. A comprehensive selection is listed below. HENRY B. WALTERS, *A History of Ancient Pottery,* 2 vol. (1905, reprinted 1971); CHARLES F. SELTMAN, *Attic Vase-Painting* (1933); VINCENT D'ARBA DESBOROUGH, *Protogeometric Pottery* (1952); G.M.A. RECHFER, *A Handbook of Greek Art,* 6th ed. (1969); *Ancient Italy* (1955); *Attic Red-Figured Vases: A Survey,* 2nd ed. (1958); and *The Craft of Athenian Pottery* (1923); ARTHUR LANE, *Greek Pottery,* 3rd ed. (1971); ROBERT H. COOK, *Greek Painted Pottery* (1960); T.B.L. WEBSTER, *Greek Terracottas* (1951); ROBERT J. CHARLESTON, *Roman Pottery* (1955); JOHN D. BEAZLEY, *Etruscan Vase Painting* (1947). Historical comparisons with modern methods and procedures are the basis of D.P.S. PEACOCK, *Pottery in the Roman World* (1982).

Islāmic pottery: There are few works easily available. The best are ARTHUR LANE, *Early Islamic Pottery,* rev. ed. (1958) and *Later Islamic Pottery,* 2nd ed. (1972); see also MAURECE S. DIMAND, *A Handbook of Muhammadan Art,* 3rd ed. rev. (1958); and ROBERT L. HOBSON, *A Guide to Islamic Pottery of the Near East* (1932).

Western pottery: Where they exist, the titles of English works on continental pottery are given below. Those listed in other languages are illustrated works that will supplement the deficiency of works in English. In the case of porcelain, English works that discuss the wares of individual factories are given only in special cases since they are extremely numerous and most general works on the subject include a bibliography. Contemporary European and American developments are well covered in TAMARA PRÉAUD and SERGE GAUTHIER, *Ceramics of the 20th Century* (1982); and RICHARD ZAKIN, *Electric Kiln Ceramics* (1981). (*Spain*): ALICE W. FROTHENGHAM, *Catalogue of Hispano-Moresque Pottery in the Collection of the Hispanic Society of America* (1936); *Talavera Pottery, with a Catalogue of the Collection of the Hispanic Society of America* (1944); *Lustreware of Spain* (1951); ALBERT VAN DER PUT, *Hispano-Moresque Ware of the XVth Century* (1904). (*Italy*): JOSEPH CHOMPRET, *Repertoire de la Mojolique Italienne,* 2 vol. (1949); BERNARD RACKHAM, *Guide to Italian Maiolica* (1933); *Catalogue of Italian Maiolica,* 2 vol. (1940); and *Italian Maiolica* (1952)—Rackham's books are the best source of information in English; ARTHUR LANE, *Italian Porcelain* (1954); GIUSEPPE MORAZZONI, *Le Porcellane Italiane* (1935). (*France and Belgium*): CHARLES DAMIRON, *La Faience artistique de Moustiers* (1919) and *La Faience de Lyon* (1926); JEANNE GIACOMOFFE, *Faiences françaises* (1963; Eng. trans., *French Faience,* 1963); HANS HAUG, *Les Faiences et porcelaines de Strasbourg* (1922); ARTHUR LANE, *French Faience,* 2nd ed. (1970), the best introduction to the subject; FRANCOIS PON-

CEITON and GEORGE SALLES, *Les Poteries Françaises* (1928); PAUL ALFASSA and JACQUES GUERIN *Porcelaine française du XVII^e au milieu du XIX^e siecle* (1932); EMILE BOURGEOIS, *Le Biscuit de Sevres au XVIII^e siecle*, 2 vol. (1909); W.B. HONEY, *French Porcelain of the 18th Century* (1950); EUGENE J. SOIL DE MORAINE, *La Manufacture imperiale et royale de porcelain de Tournay*, 3rd ed. of his *Ceramique tournaisienne* by LUCIEN DELPLACE DE FORMANOIR (1937); GEORGE SAVAGE, *Seventeenth and Eighteenth Century French Porcelain* (1960); PIERRE VERLET, SERGE GRANDJEAN, and MARCELLE BRUNET, *Sevres* (1953). *(Germany and Austria):* KARL KOETSCHAU, *Rheinisches Steinzeug* (1924); HANS MEYER, *Böhmisches Porzellan and Steingut* (1927); GUSTAV E. PAZAUREK, *Deutsche Fayence and Porzellan-Hausmaler*, 2 vol. (1925, reprinted 1970) and *Steingut: Formgebung and Geschichte* (1921); D. RIESEBIETER, *Die deutschen Fayencen des 17. and 18. Jahrhunderts* (1921), the most comprehensive general work on the subject; EDMUND W. BRAUN and JOSEPH FOLHESICS, *Geschichte der K.K. Wiener Porzellan-Manufaktur* (1907); HANS CHRIST, *Ludwigsburger Porzellanfiguren* (1921); JOHN F. HAYWARD, *Viennese Porcelain of the Du Paquier Period* (1952); FRIEDRICH H. HOFMANN, *Frankenthaler Porzellan*, 2 vol. (1911); *Geschichte der Bayerischen Porzellan-Manufaktur Nymphenburg*, 3 vol. (1921–23); and *Das Porzellan-Manufaktur Nymphenburg*, 3 vol. (1921–23); and *Das Porzellan der Europäischen Manufakturen im 18. Jahrhundert* (1932); V.B. HONEY, *Dresden China*, 2nd ed. (1954) and *Germain Porcelain* (1948); GEORG LENZ, *Berliner Porzellan: Die Manufaktur Friedrichs des Grossen, 1763–1786*, 2 vol. (1913); HUGO MORLEY-FLETCHER, *Antique Porcelain in Color: Meissen* (1971); E. POCHE, *Bohemian Porcelain* (n.d.); KARL ROEDER and HICHE OPPENHEIM, *Das Höchster Porzellan* (1925); HAK SAUERLANDT, *Deutsche Porzellanfiguren des XVIII. Jahrhunderts* (1923); GEORGE SAVAGE, *18th–Century German Porcelain*, 2nd ed. (1967); CHRISTIAN SCHERER, *Das Fürstenberger Porzellan* (1909). *(Switzerland):* SIEGFRIED DUCRET, *Zürcher Porzellan des 18. Jahrhunderts* (1944). *(The Netherlands);* CAROLINE H. DE JONGE, *Delft Aardewerk* (1965; Eng. trans., DELFT-CERAMICS, 1969) and *Nederlandse tegels* (1971; Eng. trans., *Dutch Tiles*, 1971); FERRAND W. HUDIG, *Delfter Fayence* (1929); JEAN JUSTICE, *Dictionnaire des marques et monogrammes de la faïence de Delft* (1920; Eng. trans., *Dictionary of Marks and Monograms of Delft Pottery*, (1930); ELISABETH NEURDENBURG, *Old Dutch Pottery and Tiles* (Eng. trans., 1923); BERNARD RACKHAM, *Early Netherlands Maiolica* (1926), a discussion of the earliest pre-Delft wares. *(Scandinavia):* RICHARD KARSSON, *Die Stralsunder Fayencefabrik, 1757–1790* (1920); ARTHUR HAYDEN, *Royal Copenhagen Porcelain* (1911); ERIK VETTERGREN, *The Modern Decorative Arts of Sweden* (Eng. trans. 1926). *(Russia):* GEORGY LUKOMSKY, *Russisches Porzellan, 1774–1923* (1924); KARVIN C. ROSS, *Russian Porcelains* (1968). *(England):* HARRY BARNARD, *Chats on Wedgwood Ware* (1924); GEOFFREY BEMROSE, *Nineteenth Century English Pottery and Porcelain* (1952); FREDERICK H. GARNER, *English Delftware* (1948); JOHN E. and EDITH HODGKIN, *Examples of Early English Pottery, Named, Dated and Inscribed* (1891); ELIZA HETEYARD, *The Life of Josiah Wedgwood*, 2 vol. (1865); ERNEST KORTON NANCE, *The Pottery and Porcelain of Swansea and Nantgarn* (1942); V.J. POUNTNEY, *Old Bristol Potteries* (1920); E. STANLEY PRICE, *John Sadler, a Liverpool Pottery Printer* (1949); BERNARD RACKHAM, *Mediaeval English Pottery* (1947) and *Early Staffordshire Pottery* (1951); BERNARD RACKHAM and HERBERT READ, *English Pottery: Its Development from Early Times to the End of the Eighteenth Century* (1924); GEORGE V. RHEAD, *The Earthenware Collector* (1920); JOSIAH WEDGWOOD, *Selected Letters*, ed. by ANN FINER and GEORGE SAVAGE (1965); DONALD TOUNER, *Handbook of Leeds Pottery* (1951); FREDERICK WILLIAMSON, *The Derby Pot Manufacturing Known as Cockpit Hill* (1931); HUGH WAKEFIELD, *Victorian Pottery* (1962); PATTERSON D. GORDON PUGH, *Staffordshire Portrait Figures and Allied Subjects of the Victorian Era* (1971); MURIEL ROSE, *Artist-Potters in England* (1955); JOSEPH L. DIXON, *English Porcelain of the Eighteenth Century* (1952); ENGLISH CERAMIC CIRCLE, *English Pottery and Porcelain: Commemorative Catalogue of an Exhibition Held at the Victoria and Albert Museum* (1949); STANLEY W. FISHER, *The Decoration of English Porcelain* (1954) and *English Blue and White Porcelain of the 18th Century* (1947); GEOFFREY GODDEN, *An Illustrated Encyclopaedia of British Pottery and Porcelain* (1966); V.B. HONEY, *Old English Porcelain* (1948); WILLIAM KING, *English Porcelain Figures of the Eighteenth Century* (1925); GEORGE SAVAGE, *18th-Century English Porcelain*, new ed. (1964); CYRIL COOK, *The Life and Work of Robert Hancock* (1948); *William Duesbury's London Account Book, 1751–1753*, with an introduction by MRS. DONALD MCALISTER (1931); WILLIAM H. TAPP, *Jefferyes Hamett O'Neal, 1734–1801* (1938). *(American Indian pottery):* G.H.S. BUSHWELL and ADRIAN DIGBY, *Ancient American Pottery* (1955); WOLFGANG HABERLAND, *The Art of North America* (1964). *(United States):* JOHN RAMSAY, *American Potters and Pottery* (1939); EDWIN A. BARBER, *Tulip Ware of the Pennsylvania-German Potters* (1903); WARREN COK, *The Book of Pottery and Porcelain*, vol. 2 (1944).

Non-Western pottery: (*China*): The best general work is still V.B. HONEY, *The Ceramic Art of China, and Other Countries of the Far East* (1945); but ROBERT L. HOBSON, *Chinese Pottery and Porcelain*, 2 vol. (1915), is often consulted. Hobson's *Wares of the Ming Dynasty* (1923) and *Later Ceramic Wares of China* (1925), are scholarly works, well illustrated for their period. *Chinese Art*, 4 vol. (1960–65), by a number of internationally known experts, covers the whole field of Chinese art, including pottery and porcelain, and is of considerable value to the student. The earliest Chinese wares are discussed in English by CHIN-TING WU in *Prehistoric Pottery in China* (1938). Wares till the Sung dynasty are discussed by BASIL GRAY in *Early Chinese Pottery and Porcelain* (1952); and by ARTHUR L. HETERINGTON in *Early Ceramic Wares of China* (1922) and *Chinese Ceramic Glazes*, 2nd rev. ed. (1948). For wares of the Ming dynasty and subsequently, see ROGER SOAKE JENYNS, *Ming Pottery and Porcelain* (1953) and *Later Chinese Porcelain*, 2nd ed. (1959). See also YUTAKA MINO, *Freedom of Clay and Brush Through Seven Centuries in Northern China* (1981); MARY TREGEAR, *Song Ceramics* (1982). (*Korea*): G. ST. G.K. GOMPERTZ, *Korean Celadon, and Other Wares of the Koryŏ Period* (1963); and CHEVON KIM, *The Ceramic Art of Korea* (1961); V. B. HONEY, *Corean Pottery* (1947). (*Japan*): Japanese porcelain is better documented than the pottery of that country. ROGER SOAKE JENYNS, *Japanese Porcelain* (1965), is the definitive work in English on the subject. See also TAOANARE MITSUOKA, *Ceramic Art of Japan* (1949); and ROGER SOAKE JENYNS, *Japanese Pottery* (1971). (*Chinese and Japanese export porcelain*): This includes works on the erroneously termed Oriental Lowestoft. MICHEL BEURDELEY, *Porcelaine de la compagnie des Indes* (1962; Eng. trans., *Porcelain of the East India Companies;* U.S. title, *Chinese Trade Porcelain;* 1962); SIR HARRY M. GARNER, *Oriental Blue and White*, 3rd ed. (1970), discusses early blue-and-white export wares; JOHN A. LLOYD HYDE, *Oriental Lowestoft* (1954); JEAN MCCLURE MUDGE, *Chinese Export Porcelain for American Trade, 1785–1835* (1962); JOHN G. PHILLIPS, *China Trade Porcelain* (1956); WALTER A. STAEHELIN, *The Book of Porcelain* (1966), a book of Chinese illustrations relating to the export trade in the 18th century; SIR A. TUDOR CRAIG, *Armorial Porcelain of the Eighteenth Century* (1925); T. VOLKER, *Porcelain and the Dutch East India Company* (1954), an examination of the records in relation to the import of Chinese and Japanese porcelain in the 17th century.

Basketry. H.H. BOBART, *Basketwork Through the Ages* (1936, reissued 1971); M.L. LEE, *Basketry and Related Art* (1948); G.M. CROWFOOT, "Textiles, Basketry and Mats," in *A History of Technology*, vol. 1 (1954); GEOFREY H.S. BUSHNELL, "Basketry," *Encyclopedia of World Art*, vol. 2, col. 387–400 (1960); H. BALFET, "La Vannerie, essai de classification," *L'Anthropologie* (1952; Eng. trans. and preface by M.A. BAUMHOFF, "Basketry: A Proposed Classification," in *Papers on Californian Archaeology*, no. 47–49, pp. 1–21, 1957), a detailed explanation of the classifications used in this article and the source of portions adapted for use here with permission of the Archaeological Survey, University of California, Berkeley; O.T. MASON, "Aboriginal American Basketry," *Annual Report, 1902* of the U.S. National Museum, pp. 171–548 (1904), a classic work on basketry; H. MUNSTERBERG, *The Folk Arts of Japan*, ch. 3 (1958); ED ROSSBACH, *Baskets as Textile Art* (1973), on the aesthetics of basket design; GLORIA ROTH TELEKI, *The Baskets of Rural America* (1957), a history of the origins and techniques of basketry. See also SHEREEN LAPLANTZ, *Pleated Basketry: The Woven Form* (1982); JOHN RICE IRWIN, *Baskets and Basket Makers in Southern Appalachia* (1982).

Metalwork. GEORGIUS AGRICOLA, *De re metallica* (1556; Eng. trans., 1912, reprinted 1950), a scholarly translation of a mining and metallurgical classic; LESLIE AITCHISON, *A History of Metals*, 2 vol. (1960), outstanding for its completeness, competence, and excellent index; *The Pirotechnia of Vannoccio Biringuccio*, trans. from the Italian with introduction and notes by CYRIL STANLEY SMITH and MARTHA TEACH GNUDI (1942), a description of Biringuccio's practices of smelting and metallurgy; HERBERT H. COGHLAN, *Notes on the Prehistoric Metallurgy of Copper and Bronze in the Old World* (1951), an authoritative study with a chapter on various methods of working, such as forging, casting, and sheet metalworking; ROBERT J. FORBES, *Metallurgy in Antiquity*, 9 vol. (1950; new ed., *Studies in Ancient Technology*, 1964–), vol. 8 devoted to the discussion of early metallurgy, the smith and his tools, gold, silver and lead, zinc and brass, and vol. 9 containing the chapters on copper, tin and bronze, and iron—these publications are authoritative and the bibliographies are comprehensive; HANNS U. HAEDEKE, *Metalwork* (1970), a study of European metalwork from the Middle Ages to the 19th century that emphasizes the socio-economic aspects of decorative arts in copper, brass, bronze, iron, and pewter; R. GOOWDWIN-SMITH,

English Domestic Metalwork (1937), deals with technology and style as well as types of domestic objects and utensils; RAYMOND LISTER, *The Craftsman in Metal* (1966), an enlightening discussion of the techniques of metalworking in various historical periods; THOMAS A. RICKARD, *Man and Metals: A History of Mining in Relation to the Development of Civilization,* 2 vol. (1932), shows that civilization was developed by the skilful use of metals in industry and the arts; CHARLES SINGER *et al.* (eds.), *A History of Technology,* 5 vol. (1954–58), the standard general reference book in the field of technology that covers the history of metalwork from early times to about 1900 AD—each subject is written by a master, the illustrations are numerous, well selected, and well explained; R.F. TYLECOTE, *Metallurgy in Archaeology: A Prehistory of Metallurgy in the British Isles* (1962), includes chapters on gold, copper and copper alloys, tin and tin alloys, lead and silver, methods of fabrication, and cites extensive references (the last half of the book is devoted to the study of iron). Later studies include JAMES A. MULHOLLAND, *A History of Metals in Colonial America* (1981); and OPPI UNTRACHT, *Jewelry Concept and Technology* (1982).

Silver and gold: (*Western*): STATON ABBEY, *The Goldsmith's and Silversmith's Handbook,* 2nd ed. rev. (1968); P. ACKERMAN, "The Art of the Parthian Silver- and Goldsmiths," E. MARGULIES, "Cloisonne Enamel," and J. ORBELI, "Sasanian and Early Islamic Metalwork," in *A Survey of Persian Art,* ed. by A.U. POPE, vol. 1 (1938); LAWRENCE ANDERSON, *The Art of the Silversmith in Mexico, 1519–1936,* 2 vol. (1941); CLARA LOUISE AVERY, *Early American Silver* (1930, reprinted 1968); GUDMUND BOESEN AND CHRISTEN A. BOJE, *Gammelt dansk sølv til bordbrug* (1948; Eng. trans., *Old Danish Silver,* 1949); KATHRYN C. BUHLER, *American Silver* (1950); BENVENUTO CELLINI, *Treatises . . . on Goldsmithing and Sculpture* (Eng. trans. 1898, reprinted 1966); MICHAEL CLAYTON, *The Collector's Dictionary of the Silver and Gold of Great Britain and North America* (1971); ERNEST M. CURRIER, *Marks of Early American Silversmiths . . .* (1938, reprinted 1970); FRANK DAVIS, *French Silver* (1970); ERIC DELIEB, *Investing in Silver,* new ed. (1970); FAITH DENNIS, *Three Centuries of French Domestic Silver,* 2 vol. (1960); JOHAN W. FREDERIKS, *Dutch Silver,* 4 vol. (1952–61), Renaissance–18th century; JOHN F. HAYWARD, *Huguenot Silver in England, 1688–1727* (1959); HENRY D. HILL, *Antique Gold Boxes* (1953); GRAHAM HOOD, *American Silver: A History of Style, 1650–1900* (1971); G.E.P. and J.P. HOW, *English and Scottish Silver Spoons,* 3 vol. (1952); G. BERNARD and THERLE HUGHES, *Three Centuries of English Domestic Silver, 1500–1820* (1968); G. BERNARD HUGHES, *Small Antique Silverware* (1957); CHARLES J. JACKSON, *English Goldsmiths and Their Marks,* 2nd ed. rev. (1921, reprinted 1964); HEINZ LEITERMANN, *Deutsche Goldschmiedekunst* (1953); Y. OKADA, "History of Japanese Ceramics and Metalwork," *Pageant of Japanese Art,* vol. 4 (1952); CHARLES C. OMAN, *English Domestic Silver,* 6th ed. (1965); JOHN MARSHALL PHILLIPS, *American Silver* (1949); JONATHAN STONE, *English Silver of the Eighteenth Century* (1965); GERALD TAYLOR, *Silver,* rev. ed. (1964) and *Continental Gold and Silver* (1967); PATRICIA WARDLE, *Victorian Silver and Silver-Plate* (1963). (*Modern*): ESBJORN HIORT, *Modern Danish Silver* (1954); GEORG JENSEN, INC., *Fifty Years of Danish Silver in the Georg Jensen Tradition* (1956); WORSHIPFUL COMPANY OF GOLDSMITHS, *Modern British Silver* (1951, 1954, 1959, 1964). (*Middle and Far East*): HENRY L. ROTH, *Oriental Silver, Malay and Chinese* (1910, reprinted 1966); HARRY L. TILLY, *The Silverwork of Burma* (1902). (*North and South America—Pre-Columbian*): JOHN ADAIR, *The Navajo and Pueblo Silversmiths* (1944, reprinted 1970); JOSE PEREZ DE BARRADAS, *Orfebrería prehispánica de Colombia,* 4 vol. (1954–58); ALFONSO CASO, "La Orfebrería, prehispánica," in *Artes de Mexico,* no. 10 (1955); DUDLEY T. EASBY, JR., "Ancient American Goldsmiths," *Natural History,* 65:401–409 (1956); MARSHALL H. SAVILLE, *The Goldsmith's Art in Ancient Mexico* (1920); ARTHUR S. WOODWARD, *A Brief History of Navajo Silversmithing* (1938). (*Sheffield plate and pewter*): FREDERICK BRADBURY, *British and Irish Silver Assay Office Marks, 1544–1968 . . .,* 12th ed. (1968); HOWARD HERSCHEL COTTERELL, *Pewter Down the Ages,* 2 pt. (1932) and *Old Pewter: Its Makers and Marks in England, Scotland and Ireland* (1929, reprinted 1963); JOHN B. KERFOOT, *American Pewter* (1924); H.J.L.J. MASSE, *Chats on Old Pewter,* ed. and rev. by RONALD F. MICHAELIS (1949); EDWARD WENHAM, *Old Sheffield Plate* (1955); SEYMOUR B. WYLER, *The Book of Sheffield Plate, with All Known Makers' Marks Including Victorian Plate Insignia* (1949).

Ironwork: MAXWELL AYRTON and ARNOLD SILCOCK, *Wrought Iron and Its Decorative Use* (1929); ARTHUR and MILDRED S. BYNE, *Spanish Ironwork* (1915); HERBERT H. COGHLAN, *Notes on Prehistoric and Early Iron in the Old World* (1956); CHARLES J. FFOULKES, *Decorative Ironwork from the XIth to the XVIIIth Century* (1913); EDGAR B. FRANK, *Petite Ferronnerie ancienne* (1948; Eng. trans., *Old French Ironwork,* 1950); J. STARKIE GARDNER, *English Ironwork of the XVIIth and XVIIIth Centuries* (1911) and *Continental Ironwork of the Renaissance and Later Periods,* rev. ed. (1930); GERALD K. GEERLINGS, *Wrought Iron in Architecture* (1929) and *Metal Crafts in Architecture* (1929); JOHN GLOAG and DEREK BRIDGWATER, *A History of Cast Iron in Architecture* (1948); JOHN HARRIS (comp.), *English Decorative Ironwork from Contemporary Source Books, 1610–1836* (1960); OTTO HOVER, *Das Eisenwerk,* 3rd rev. ed. (1953; Eng. trans., *A Handbook of Wrought Iron from the Middle Ages to the End of the Eighteenth Century;* U.S. title, *Wrought Iron: Encyclopedia of Ironwork;* 1962); J. SEYMOUR LINDSAY, *Iron and Brass Implements of the English House,* rev. ed. (U.S. title, *Iron and Brass Implements of the English and American House;* 1964); RAYMOND LISTER, *Decorative Wrought Ironwork in Great Britain* (1957) and *Decorative Cast Ironwork in Great Britain* (1960); JOSEPH NEEDHAM, "Iron and Steel Production in Ancient and Medieval China," in *Clerks and Craftsmen in China and the West,* ch. 8 (1970); WALLACE NUTTING, *Early American Ironwork* (1919); ALBERT H. SONN, *Early American Wrought Iron,* 3 vol. (1928).

Leadwork: WILLIAM R. LETHABY, *Leadwork, Old and Ornamental, and for the Most Part English* (1893); SIR LAWRENCE WEAVER, *English Leadwork: Its Art and History* (1909); GEORGE ZARNECKI, *English Romanesque Lead Sculpture: Lead Fonts of the Twelfth Century* (1957).

Copper, brass, and bronze: FREDERICK BURGESS, *Chats on Old Copper and Brass,* rev. ed. (1954); HENRY J. KAUFFMANN, *American Copper and Brass,* (1968); ALBERT J. KOOK, *Early Chinese Bronzes* (1970); HERMANN LEISINGER, *Romanesque Bronzes* (*op. cit.*); DAVID G. MITTEN and SUZANNAH F. DOERINGER, *Master Bronzes from the Classical World* (1968); HUGO MUNSTERBERG, *Chinese Buddhist Bronzes* (1967); *Macklin's Monumental Brasses,* rev. by JOHN PAGE-PHILLIPS (1969); JOHN T. PERRY, *Dinanderie: A History and Description of Mediaeval Art Work in Copper, Brass, and Bronze* (1910); JOHN POPE-HENNESSEY, *Renaissance Bronzes from the Samuel H. Kress Collection* (1965); GEORGE SAVAGE, *A Concise History of Bronzes* (1968); C. SIVARAMAMURTI, *South Indian Bronzes* (1963); ERNEST R. SUFFLING, *English Church Brasses: From the 13th to the 17th Century* (1970); ALEXANDER SOPER, *Chinese, Korean, and Japanese Bronzes* (1966); LEON UNDERWOOD, *Bronzes of West Africa,* 2nd ed. (1968); WILLIAM WATSON, *Ancient Chinese Bronzes* (1962).

Decorative metalwork: LESLIE AITCHISON, *A History of Metals,* 2 vol. (1960); J. STARKIE GARDNER, *Ironwork* (various editions, 1892–1930); HERMANN LEISINGER, *Romanesque Bronzes: Church Portals in Mediaeval Europe* (1957); CYRIL STANLEY SMITH, *A History of Metallography: The Development of Ideas on the Structure of Metals Before 1890* (1960).

Enamelwork. *Materials and techniques:* KENNETH FRANCIS BATES, *Enameling: Principles and Practice* (1951); HERBERT MARYON, *Metalwork and Enamelling,* 4th ed. (1959), contains a useful bibliography; MARGARET SEELER, *The Art of Enameling* (1969).

Periods and centres of production: KLAUS WESSEL, *Byzantine Enamels from the 5th to the 13th Century* (1968); LUIGI MALLE, *Cloisonnés bizantini* (1970); SHALVA AMIRANASHVILI, *Medieval Georgian Enamels of Russia* (1964); MARY CHAMOT, *English Mediaeval Enamels* (1930); W.L. HILDBURGH, *Medieval Spanish Enamels and Their Relation to the Origin and the Development of Copper Champlevé Enamels of the Twelfth and Thirteenth Centuries* (1936); MARIE-MADELEINE GAUTNIER, *Ernaux limousins champlevés des XII^e, XIII^e, and XIV^e siècles* (1950); J.J. MARQUET DE VASSELOT, *Les Crosses limousines du XIII^e siècle* (1941); PAUL THOBY, *Les Croix limousines de la fin du XII^e siècle au debut du XIV^e siècle* (1953); KATIA GUTH-DREYFUS, *Transluzides Email in der ersten Hälfte des 14 Jahrhunderts am Ober-, Mittel-, und Niederrhein* (1954); PHILIPPE VERDIER, *Catalogue of the Painted Enamels of the Renaissance in the Walters Art Gallery* (1967), with an excellent bibliography; HENRI CLOUZOT, *Dictionnaire des miniaturistes sur émail* (1924) and *La Miniature sur émail en France* (1928); PIERRE F. SCHNEEBERGER, *Les Peintres sur émail genevois au XVII^e et au XVIII^e siècle* (1958); CHARLES BEARD, "Bavarian Enamels of the Seventeenth Century," *Connoisseur,* 97:267–271 (1936); EDWARD DILLON, "English Enamels on Brass of the Seventeenth Century," *Burlington Magazine,* 16:261 (1910); EGAN MEW, *Battersea Enamels* (1926), out of date in some respects; SANDOR MIHALIK, *Emailkunst im alten Ungarn* (1961; Eng. trans., *Old Hungarian Enamels,* 1961); HARRY GARNER, *Chinese and Japanese Cloisonné Enamels* (1962), with a full bibliography; LAWRENCE A. COBEN and DOROTHY C. FERSTER, *Japanese Cloisonne: History, Technique, and Appreciation* (1982), is meant for collectors and scholars.

Lacquerwork. *European lacquer:* HANS HUTH, *Lacquer of the West: The History of a Craft and an Industry, 1550–1950* (1971), a concise, well-written statement, the most complete to date, based on a life-time study, with many excellent illustra-

tions. ERICH KARSTEN, *Lackrohstoff-Tabellen*, 7th ed. (1981), a monograph mainly on tables; LUCY MAXYM, *Russian Lacquer, Legends and Fairy Tales* (1981); and OLGA VORONOVA (comp.), *Lacquer Miniatures from Mstiora* (1980), dealing with original folk miniature painting and the specific techniques developed in Central Russia.

Chinese lacquer: FILIPPO BONANNI, *Trattato sopra la vernice comunemente detta cinese* (1720); PERE L. D'INCARVILLE, "Mémoire sur le Vernis de la Chine," in the *Mémoires* of the Académie Royale des Sciences (1760); STEPHEN W. BUSHELL, *Chinese Art*, vol. 1 (1904); EDWARD F. STRANGE, *Catalogue of Chinese Lacquer in the Victoria and Albert Museum* (1925) and *Chinese Lacquer* (1926); R.S. JENYNS, "Chinese Lacquer," *Transactions of the Oriental Ceramic Society*, vol. 17 (1939–40); FRITZ LOW-BEER, "Chinese Lacquer of the Early 15th Century" and "Chinese Lacquer of the Middle and Late Ming Period," *Bulletin of the Museum of Far Eastern Antiquities*, no. 22 and 24 (1950–52); KURT HERBERTS, *Das Buch der ostasiatischen Lackkunst* (1959; Eng. trans., *Oriental Lacquer*, 1962); WERNER SPEISER, *Lackkunst in Ostasien* (1965); HARRY M. GARNER, "Diaper Backgrounds on Chinese Carved Lacquer," *Ars Orientalis*, 6:165–190 (1966), and "A Group of Chinese Lacquers with Basketry Panels," *Archives of Asian Art*, 20:6–24 (1966–67); LEE YU-KUAN, *Oriental Lacquer Art* (1972).

Japanese lacquer: JOHANN J. REIN, *Japan, nach Reisen und Studien*, vol. 2 (1886; Eng. trans., *The Industries of Japan*, vol. 2, 1889, reprinted 1969); MICHAEL TOMKINSON, *A Japanese Collection*, 2 vol. (1898); *L'Historie de l'art du Japon*, Paris Exhibition (1900); FRANK BRINKLEY, *Japanese Temples and Their Treasures*, 3 vol. (1910); *Official Catalogue of the Japan-British Exhibition* (1910); EDWARD F. STRANGE, "The Incense Ceremony and Its Utensils," Japan Society *Transactions*, 21:28–38 (1923–24), and *Catalogue of Japanese Lacquer and Inrō in the Victoria and Albert Museum* (1924); MARTHA BOYER, *Japanese Export Lacquers from the Seventeenth Century in the National Museum of Denmark* (1959); BEATRIX VON RAGUE, *Geschichte der japanischen Lackkunst* (1967). NATIONAL MUSEUM OF MODERN ART. TOKYO, *Japanese Lacquer Art: Modern Masterpieces* (1982; originally published in Japanese, 1981).

Mosaic. *General works:* A. BLANCHET, *La Mosaique* (1928); E.W. ANTHONY, *A History of Mosaics* (1935, reprinted 1968); P. FISCHER, *Das Mosaik* (1969). H.P. L'ORANGE and P.J. NORDHAGEN, *Mosaikk* (1958); Eng. trans., 1966), deals with the history of the art from its beginnings to *c.* AD 900.

Greek and Roman mosaic: Of the literature on Greek and Roman mosaic, the following works are of particular importance: (*pebble mosaic*): R.S. YOUNG, "Gordion 1956: Preliminary Report," *Am. J. Archaeology*, 61:319–331 (1957); D.M. ROBINSON, *Excavations at Olynthus*, vol. 5, 8, and 13 (1933, 1938, 1950). (*pebble-tessera mosaic*): C.M. ROBERTSON, "Greek Mosaics," *J. Hellenic Stud.*, 85:72–89 (1965); B.R. BROWN, *Ptolemaic Paintings and Mosaics and the Alexandrian Style* (1957); J. CHANDNARD, *Les Mosaïques de la maison des masques* (1933). (*floor mosaic—Roman*): *Colloque sur la mosaïque gréco-romaine, Actes* (1965); H.E. BLAKE, articles on Roman mosaics in *Mem. Am. Acad. Rome*, 8:7–160, 13: 69–214, and 17:81–130 (1930, 1936, 1940); K.M. PHILLIPS, "Subject and Technique in Hellenistic-Roman Mosaics: A Ganymede Mosaic from Sicily," *Art Bull.*, 42:243–262 (1960); R.P. HENKS, *Catalogue of the Greek, Etruscan and Roman Paintings and Mosaics in the British Museum* (1933); D. LEVI, *Antioch Mosaic Pavements* (1947); I. LAVIN, "The Hunting Mosaics of Antioch and Their Sources," *Dumbarton Oaks Papers*, no. 17 (1963). H. STERN, "Origine et débuts de la mosaïque murale," *Études d'archéologie classique*, vol. 2 (1959).

Early Christian mosaic: M. VAN BERCHEN and E. CLOUZOT, *Mosaïques chrétiennes du IV^e^ au X^e^ siecle* 1924); G. MATTHIAE, *Mosaici medioevali delle chiese di Roma* (1967); W.F. OAKESHOTT, *The Mosaics of Rome, from the Third to the Fourteenth Centuries* (1967); H. STERN, "Les Mosaïques de l'Église de Sainte-Constance a Rome," *Dumbarton Oaks Papers*, no. 12 (1958); C. CECCHELLI, *I mosaici della basilica di S. Maria Maggiore* (1956); C. RICCI, *Tavole storiche dei mosaici di Ravenna*, 4 vol. (1930–37); F.W. DEICHMANN, *Frühchristliche Bauten and Mosaiken von Ravenna* (1958); G. BRUSIN and P.L. ZOVATTO, *Monumenti paleocristiani di Aquileia e di Grado* (1957); J.L. MAIER, *Le Baptistere de Naples et ses mosaïques* (1964); B. BRENK, "Die ersten Goldmosaiken der christlichen Kunst," *Palette* (Basel), 38:16–25 (1971), a work concerning the earliest use of gold cubes in mosaics.

Early Byzantine mosaic: G. BRETT *et al.*, *The Great Palace of the Byzantine Emperors* (1947); C. DIEHL, M. LE TOURMEAU, and H. SALADIN, *Les Monuments chretiens de Salonique* (1918); T. SCHMIT, *Die Koimesis-Kirche von Nikaia* (1927); P.A. UNDERWOOD, "The Evidence of Restorations in the Sanctuary Mosaics of the Church of the Dormition at Nicaea," *Dumbarton Oaks Papers*, no. 13 (1959); M. AVIYONAH and M. SCHAPIRO, *Israel: Ancient Mosaics* (UNESCO 1954–60); E. KITZINGER, *Israeli Mosaics of the Byzantine Period* (1965); K. WEITZMANN, "The Mosaic in St. Catherine's Monastery on Mount Sinai," *Am. Phil. Soc. Proc.*, 110:392–405 (1966); K.A.C. CRESWELL, *Early Muslim Architecture*, 2nd ed., vol. 1 (1969), including K. VAN BERCHEK, "The Mosaics of the Dome of the Rock in Jerusalem and of the Great Mosque in Damascus"; G. BOVINI, *Mosaici di Ravenna* (1956; Eng. trans., *Ravenna Mosaics*, (1956), and *La vita di Cristo nei mosaici di S. Appollinare Nuevo di Ravenna* (1959). B.J. NORDHAGEN, "The Mosaics of John VII (705–707 AD)," *Acta. Institutum Romanum Nowegiae*, 2: 121–166 (1965); GUNILLA Å. KERSTRÖM-HOUGEN, *The Calendar and Hunting Mosaics of the Villa of the Falconer in Argos* (1974).

Middle and late Byzantine: DEMUS, *Byzantine Mosaic Decoration* (1948), A. GRABER, *La Peinture Byzantine* (1953; Eng. trans., *Byzantine Painting*, 1953); T. WHITTEMORE, *The Mosaics of Haghia Sophia at Istanbul*, 4 vol. (1933–52); P.A. UNDERWOOD and E.J.W. HAWKINS, "The Mosaics of Hagia Sophia at Istanbul: The Portrait of the Emperor Alexander," *Dumbarton Oaks Papers*, no. 15 (1961); E.J.W. HAWKINS, "Further Observations on the Marthex Mosaic in St. Sophia at Istanbul," *ibid.* 22 (1968); C.A. MANGO "Materials for the Study of the Mosaics of St. Sophia at Istanbul," *ibid.* 8 (1962); P.A. UNDERWOOD, *The Kariye Djami*, 3 vol. (1967); E. DIEZ and O. DEMUS, *Byzantine Mosaics in Greece, Hosios Lucas and Daphni* (1921); A. GRABAR and M. CHAIZIDAKIS, *Greece: Byzantine Mosaics* (UNESCO 1960); V.N. LAZAREV, *Old Russian Murals and Mosaics: From the 11th to 16th Century* (1966).

Medieval mosaics in the West: W.F. OAKESHOTT, *The Mosaics of Rome, from the Third to the Fourteenth Centuries* (1967); O. DEMUS, *The Mosaics of Norman Sicily* (1950); E. KITZENGER, "The Mosaics of the Cappella Palatina in Palermo," *Art Bull.*, 31:269–292 (1949); *The Mosaics of Monreale* (1960); A. DEWITT (ed.), *I mosaici del Battistera di Firenze*, 4 vol. (1954–59); H. KIER, *Der mittelalterliche Schmuckfussboden* (1970); A. PRANDI, "Pietro Cavallini a S. Maria in Trastevere," *Rivista dell'Istituto Nazionale d'Archeologia e Storia dell'Arte*, 1: 282–297 (1952); R. DERTEL, "Wandmalerei and Zeichnung in Italien," *Mitteilungen des Kunsthistorischen Institutes in Florenz*, 5:217–314 (1937–40), on the technique; F. FORLATI, "La tecnica dei primi mosaici marciani," *Arte veneta*, 3:85–87 (1949); HETTY JOYCE, *The Decoration of Walls, Ceilings, and Floors in Italy in the Second and Third Centuries A.D.* (1981).

Renaissance to modern: The best surveys are those contained in E.V. ANTHONY, *A History of Mosaics* (1935, reprinted 1968); and P. FISCHER, *Das Mosaik* (1969). Specific instances are discussed in FRANK R. DIFEDERICO, *The Mosaics of Saint Peter's: Decorating the New Basilica* (1983); and ALVAR GONZÁLEZ-PALACIOS, *The Art of Mosaics: Selections from the Gilbert Collection* (1982).

Stained glass. Illustrated monographs include: COMITE INTERNATIONAL D'HISTOIRE DE L'ART, *Corpus Vitrearum Medii Aevi* (1956–), a series intended when complete to document all medieval stained glass extant; J. BAKER and A. LAMMER, *English Stained Glass* (1960), probably the best collection of high-quality detail photographs of medieval stained glass ever published; H.E. READ, *English Stained Glass* (1926); A.C. SEWTER, *The Stained Glass of William Morris and His Circle* (1972); M. AUBERT *et al.*, *Le Vitrail française* (1958), the standard work on French stained glass, although marred by many poor reproductions. This fault is remedied in part by the following works: M. AUBERT, *Stained Glass of the XIIth and XIIIth Centuries from French Cathedrals* (1947); and E. VON WITZLEBEN, *French Stained Glass* (1966). H. WENTZEL, *Meisterwerke der Glasmalerei*, 2nd ed. (1954), is the standard work on German medieval stained glass; E. VON WITZLEBEN, *Farbwunder Deutscher Glasmalerei aus dem Mittelalter* (1965) is the most copiously illustrated recent monograph on German medieval stained glass. S. BEEH-LUSTENBERGER, *Glasmalerei um 800–1900 im Hessischen Landesmuseum in Darmstadt* (1967), an excellent guide to one of the largest museum collections of medieval stained glass; P. WEMBER, *Johan Thorn Prikker: Glasfenster, Wandbilder, Ornamente 1891–1932* (1966); G. MARCHINI, *Italian Stained Glass Windows* (1957); M. STETTLER, *Swiss Stained Glass of the Fourteenth Century from the Church of Koenigsfelden* (1949); and F. ZSCHOKKE, *Medieval Stained Glass in Switzerland* (Eng. trans. 1947). See also JAMES STURM, *Stained Glass from Medieval Times to the Present: Treasures to Be Seen in New York* (1982); and ERNE R. FRUEH and FLORENCE FRUEH, *Chicago Stained Glass* (1983).

Books on aesthetic analysis include J.R. JOHNSON, *The Radiance of Chartres: Studies in the Early Stained Glass of the Cathedral* (1965), valuable not only for its somewhat too sweeping criticism of Viollet-le-Duc but for its original analysis of the effect of the twilight atmosphere of the cathedral upon our perception of its stained-glass windows; and R. SOWERS, *Stained Glass: An Architectural Art* (1965), a thoroughly illus-

trated analysis of the relation between stained glass and architecture, with numerous photographs of contemporary stained glass. DAVID EVANS, *A Bibliography of Stained Glass* (1982), is also recommended.

Stained-glass techniques are discussed in THEOPHILUS (RUGERUS), *Diversarum Artium Schedula* (1847; Eng. trans. 1963), the earliest account of stained-glass window-making techniques, now believed to have been written in the early 12th century; C. WINSTON, *Hints on Glass Painting* (1847), and his *Memoirs* (1865), two books containing some of the most thorough and perceptive analyses of medieval glass-painting techniques ever written; E. VIOLLET-LE-DUC, "Vitrail," in *Dictionnaire Raisonne de l'architecture française*, vol. 9 (1868; Eng. trans., "Mediaeval Stained Glass," 1946), still valuable for its many acute observations; and C.W. WHALL, *Stained Glass Work* (1905), a thorough craft manual by one of the leading turn-of-the-century stained-glass artists in England. Recent manuals include E.L. ARMITAGE, *Stained Glass* (1959); P. REYNTIENS, *The Technique of Stained Glass* (1967); and R. and G. MECALF, *Techniques of Stained Glass* (1971). Pictorial works can also be of interest: M.J. GRADL (ed.), *Authentic Art Nouveau Stained Glass Designs in Full Color* (1983); CONNIE EATON, *Oval Stained Glass Pattern Book* (1983); ANITA ISENBERG and SEYMOUR ISENBERG, *How to Work in Stained Glass*, 2nd ed. (1983).

History of glass design. There is ample literature on the history of glass. The following selection of titles includes basic reference works and handbooks as well as some specialized studies many of which contain bibliographical references. In addition, the *Journal of Glass Studies*, issued annually by The Corning Museum of Glass, includes extensive bibliographies.

The basic sources for medieval glassmanufacture are HERACLIUS, *Von den Farben und Künsten der Römer*, ed. by ALBERT ILG (1873); and THEOPHILUS PRESBYTER, *Schedula diversarum artium*, ed. by ALBERT ILG (1874; Eng. trans., *On Divers Arts: The Treatise of Theophilus*, 1963). GEORG AGRICOLA, *De re metallica* (1556; Eng. trans., 1912, reprinted 1950); and particularly ANTONIO NERI, *L'arte vetraria* (1612; Eng. trans. by CHRISTOPHER MERRET, *The Art of Glass . . .*, 1662), describe in detail glassmaking in the 16th and 17th centuries. See also JOHANN KUNCKEL, *Ars vetraria experimentalis*, 2 pt. (1679). Other technological studies are APSLEY PELLATT, *Curiosities of Glass Making* (1849); and ALFRED LUCAS, *Ancient Egyptian Materials and Industries*, 4th ed. rev. (1962). Development of glass technology in history is discussed in RUTH HURST VOSE, *Glass* (1980).

EDWARD DILLON, *Glass* (1907); ROBERT SCHMIDT, *Das Glas*, 2nd ed. (1922); and W.B. HONEY, *Glass: A Handbook . . . Victoria and Albert Museum* (1946), are among the best and most comprehensive general surveys of the history of glass. *Masterpieces of Glass* (1968), a catalog of some of the holdings in the British Museum, is the most recent scholarly publication on the subject in general, accompanied by a large bibliography. CHARLES G. JANNEAU, *Modern Glass* (1931), is a review of world glass at the beginning of the 1930s. For a general study of the international development of art glass, see ADA BUCH POLAK, *Modern Glass* (1962). GEOFFREY W. BEARD, *Modern Glass* (1968), provides a brief account of modern glasswork from various countries.

Comprehensive illustrative material on glass of the ancient world is found in GUSTAVUS A. EISEN and FAHIM KOUCHAKJI, *Glass*, 2 vol. (1927); the most scholarly survey is that of THE CORNING MUSEUM, *Glass from the Ancient World: The Ray Winfield Smith Collection* (1957). Roman glass in particular was treated exhaustively by ANTON KISA in *Das Glas im Altertume*, 3 vol. (1908). Basic treatises on pre-Roman glass include H.C. BECK, "Glass Before 1500 B.C.," in *Ancient Egypt and the East*, pt. 1, pp. 7–21 (June 1934); POUL FOSSING, *Glass Vessels Before Glass-Blowing* (1940); and BIRGIT NOLTE, *Die Glasgefässe im alten Ägypten* (1968). In addition to KISA (*op. cit.*), general books on Roman glass, such as MORIN-JEAN, *La Verrerie en Gaule sous l'Empire romain* (1913); CLASINA ISINGS, *Roman Glass from Dated Finds* (1957); and DONALD B. HARDEN, *Roman Glass from Karanis Found by the University of Michigan Archaeological Expedition in Egypt 1924–29* (1936), are important for the understanding of this period. The latter has become the standard reference work for describing and cataloging ancient glass in general.

Western glass of the 5th–8th centuries is treated in detail by D.B. HARDEN, "Glass Vessels in Britain and Ireland, A.D. 400–1000," in *Dark Age Britain* (1956). The standard handbooks on Islāmic and Western medieval glass are still CARL J. LAMM, *Mittelalterliche Gläser und Steinschnittarbeiten aus dem Nahen Osten*, 2 vol. (1929–30); and FRANZ RADEMACHER, *Die deutschen Gläser des Mittelalters* (1933). Byzantine glass is described in JOSEPH PHILIPPE, *Le Monde byzantin dans l'histoire de la verrerie, V^e–XVI^e siècle* (1970).

The basic handbooks on French and Belgian glass are JAMES BARRELET, *La Verrerie en France de l'époque gallo-romaine à nos jours* (1953); and RAYMOND CHAMBON, *L'Histoire de la verrerie en Belgique du II^e siècle à nos jours* (1955), the latter including ample bibliographic references on literary sources. WILLIAM A. THORPE, *A History of English and Irish Glass*, 2 vol. (1929), is still the standard reference work on English glass while HUGH WAKEFIELD covers *Nineteenth Century British Glass* (1961). German, Bohemian, and Austrian glass is treated exhaustively in ROBERT SCHMIDT, *Die Gläser der Sammler Mühsam*, 2 vol. (1914–27).

For polychrome painting on vessels, see AXEL VON SALDERN, *German Enameled Glass* (1965). The handbooks on glass from *c.* 1800 to *c.* 1900 are GUSTAV PAZAUREK, *Gläser der Empire und Biedermeierzeit* (1923) and *Moderne Gläser* (1901). ASTONE GASPARETTO, *Il vetro di Murano dalle origini ad oggi* (1958), is the basic reference work on Venetian glass. The best surveys on Spanish glass are JOSEP GUDIOL Y RICART, *Los vidrios catalanes* (1941); and ALICE WILSON FROTHINGHAM, *Spanish Glass* (1964). For Scandinavian material, ADA BUCH POLAK, *Gammelt Norsk Glass* (1953); and HERIBERT SEITZ, *Äldre Svenska Glas . . .* (1936), should be consulted—both contain an English summary.

Glass in the United States has been dealt with in great detail by GEORGE S. and HELEN MCKEARIN in *American Glass* (1948) and *Two Hundred Years of American Blown Glass*, rev. ed. (1966). LURA W. WATKINS, *American Glass and Glassmaking* (1950, reprinted 1970), presents a useful outline of 19th- and 20th-century American glass. RAY and LEE GROVER, *Art Glass Nouveau* (1967), is valuable for its colour illustrations of 19th- and 20th-century fancy glasses in American collections. See also MARY JEAN MADIGAN, *Steuben Glass: An American Tradition in Crystal* (1982); and GERALD STEVENS, *Glass in Canada* (1982).

On Chinese glass, see W.C. WHITE, *Tombs of Old Lo-Yang* (1934); FRIEDRICH HIRTH, *China and the Roman Orient*, pp. 228–234 (1885); W.B. HONEY, "Early Chinese Glass," *Burlington Magazine*, 71:211–223 (1937); and H.C. BECK, "Far Eastern Glass: Some Western Origins," *Bulletin of the Museum of Far Eastern Antiquities*, 10:1–64 (1938).

Delhi

Delhi is the second largest city of India, surpassed in population only by Greater Bombay (Mumbai). New Delhi, the capital of India, lies immediately to the south of Delhi (popularly known as Old Delhi); both are within the Delhi national capital territory. Besides being at the political centre of the country, Delhi is also a focal point in India's transportation network.

Delhi is situated in north-central India about 100 miles (160 kilometers) south of the Himalayas and stands on the west (right) bank of the Yamuna River, a tributary of the Ganges. The national capital territory lies at an elevation between 700 and 1,000 feet (213 and 305 metres) and covers an area of 573 square miles (1,483 square kilometres). Of this area, Old Delhi occupies 360 square miles and New Delhi 169 square miles. The national capital territory is bounded to the east by the state of Uttar Pradesh and to the north, west, and south by Haryāna. It generally has been presumed that the city was named for Rājā Dhilu, a king of the 1st century BC, and that the various names by which it has been known (Delhi, Dehli, Dillī, and Dhillī) have been corruptions of this name.

Delhi has been the capital city of a succession of mighty empires and powerful kingdoms, and numerous ruins mark the sites of the various cities. According to popular tradition, the city has changed its locality a total of seven times, although some authorities, who take smaller towns and strongholds into account, claim it has changed its site as many as 15 times. All of these locations are confined to a triangular area of about 70 square miles called the Delhi triangle. Two sides of this triangle are represented by the rocky hills of the Arāvalli Range in the west and south and the third side by the shifting channel of the Yamuna River. The present site of Delhi is bounded to the west by a northern extension of the Arāvali Range known as the Delhi Ridge.

This article is divided into the following sections:

Physical and human geography

THE LANDSCAPE

Climate. The climate of Delhi is characterized by extreme dryness, with intensely hot summers. It is associated with a general prevalence of continental air, which moves in from the west or northwest, except during the season of the monsoon (rain-bearing wind), when an easterly to southeasterly influx of oceanic air brings increased humidity. The summer season lasts from mid-March to the end of June, with average maximum and minimum temperatures of 97° F (36° C) and 77° F (25° C); it is characterized by frequent thunderstorms and squalls, which are most frequent in April and May. The monsoon season, following the hot summer, continues until the end of September, with an average rainfall of about 26 inches (660 millimetres). The post-monsoon period of October and November constitutes a transition period from monsoon to winter conditions. The winter season extends from late November to mid-February. The air in Delhi is dry for most of the year, with low relative humidity from April to June and markedly higher humidity in July and August, when weather conditions are oppressive. Delhi's mean daily temperature is highest in May; and the monthly mean temperature is highest in June, which is also the month when the night temperature is at its maximum. The mean daily temperature may rise as high as 110° F (43° C). The coldest month is January, when both the mean maximum temperature and the mean minimum temperature are at their lowest—70° F (21° C) and 45° F (7° C), respectively.

Temperature and rainfall

Air and water pollution have increased with the growth of population, industry, and the use of motor vehicles. Sometimes a temperature inversion (which can occur when a warm air mass remains over a land surface that cools during the night) forms in the winter months, which traps pollutants, prevents them from dispersing, and increases contamination considerably.

Plant and animal life. The natural plant cover in the Delhi area varies according to the physical features with which it is associated. The ridges and hillsides abound in thorny trees, such as acacias. During the monsoon season, herbaceous species grow in profusion. The sissoo (shisham; *Dalbergia sissoo*) tree, which yields a dark brown and durable timber, is commonly found in the Bāngar (Plain) area of the national capital territory. Riverine vegetation, consisting of weeds and grass, occurs on the banks of the Yamuna. New Delhi is known for its avenues of flowering shade trees, such as the neem (*Azadirachta indica;* a drought-resistant tree with a pale yellow fruit), jaman (*Syzygium cumini;* a tree with an edible grapelike fruit), mango, pipal (*Ficus religiosa;* a fig tree), and sissoo. It is also known for numerous flowering plants, which provide a splash of colour during the winter. These include a large number of multicoloured seasonals: chrysanthemums, phlox, violas, and verbenas. The transition from winter to spring is very gradual, and only the flowers can testify to changing conditions, with chrysanthemums in December yielding place to roses in February.

New Delhi's avenues of shade trees

The animal life of the national capital territory is similarly diverse. Carnivorous mammals such as hyenas, foxes, wolves, jackals, and leopards inhabit the ravine lands and hilly ridges. Antelope and wild boars, once common, are now rare in the wild. Monkeys are found in the city around some temples and ruins. Birdlife is profuse and includes partridge, pigeons, jungle crows, parrots, and bush quail. Peafowl are numerous on the hilly ridges. The Yamuna abounds in fish, and the region's lakes attract flocks of migratory birds in winter.

The city layout. The city plan of Delhi is a mixture of contrasting old and new road and circulation patterns. The contrast between the convoluted form of the old city and the diagonal features of the modern traffic arteries in New Delhi is particularly striking.

The street pattern of Old Delhi reflects some of the older requirements of defense, with a few transverse streets leading from one major gate to another. Occasionally a through street from a subsidiary gate leads to the main

Central Delhi–New Delhi.

axes. The other Old Delhi streets tend to be irregular in direction, length, and width and are suitable only for pedestrian traffic. Thus, the pattern as a whole consists of a confusing mixture of narrow and winding streets, culs-de-sac, alleys, and byways giving access to residences and commercial areas.

In sharp contrast to Old Delhi, the Civil Lines (residential areas originally built by the British for senior officers) in the north and New Delhi in the south present an aspect of relative openness, characterized by green grass and trees, order, and quiet.

When the decision was made in 1911 to transfer the capital of India from Calcutta to Delhi, and a town planning committee was formed, a site was chosen three miles south of the existing city of Delhi, around Rāisīna Hill. This was a well-drained, healthy area between the ridge and the river that provided ample room for expansion. The Rāisīna Hill, commanding a view of the entire area, stood 50 feet (15 metres) above the plain, but the top 20 feet were blasted off to make a level plateau for the major government buildings and to fill in depressions. With this low acropolis as the focus, the plan was laid out.

The New Delhi plan was characterized by wide avenues with trees in double rows on either side, creating vistas and connecting various points of interest. Almost every major road has a specific focal point closing the vista so that no avenue is lost in the horizon. Besides the diagonal road pattern, the most prominent feature of the plan is the Central Vista Park, starting from the National Stadium in the east, continuing through the All India War Memorial Arch (popularly called the India Gate) and the Central Secretariat (Kendriya Sachivālaya), and culminating in the west at the Presidential House (Rāshtrapati Bhavan). This is the main east–west axis; it divides New Delhi into two parts, with the fashionable shopping centre, Connaught Place, in the north and extensive residential colonies in the south.

The Central Vista Park

Land use. The pattern of land use in Delhi was influenced considerably by the implementation (albeit partial) of the Delhi Development Authority's 20-year (1962–81) master plan. Broadly, public and semipublic land use was concentrated in the Central Secretariat area of New Delhi and in the Old Secretariat area in the Civil Lines, with subsidiary centres developing in the Indraprastha Estate (an office complex) in the east and in Ramakrishnapuram (an office-cum-residence complex) in the south. A large number of small manufacturing establishments have entrenched themselves in almost every part of Old Delhi, but the main industrial areas have become concentrated along Najafgarh Mārg (Shrivāji Mārg), in the west, and on Mathura Mārg, in the south, where a large planned industrial estate (Okhla) has been established. Areas for commercial land use are confined mainly to Chāndnī Chowk and Khāri Bāoli (both in the north), the Sadar Bāzār of Old Delhi, the Ajmal Khān Mārg of Karol Bāgh in western Delhi, and the Connaught Place area of New Delhi. A number of district and local shopping centres have also developed in other localities.

The University of Delhi is located in the north, where a number of educational institutions for college education and for higher studies are located. Another educational complex that includes Jawaharlal Nehru University, the Indian Institute of Technology, and other institutions has been developed in southern Delhi.

Traditional areas. In a city such as Delhi, which bears the impress of history, there is a clear distinction between areas where indigenous influences are uppermost and areas characterized by colonial and modernizing influences. Although the social structure of Delhi has changed from coherence to a heterogeneity that is in keeping with its position as the national capital, certain residential neighbourhoods in Old Delhi, in the Civil Lines, in government housing areas, and in more recently developed areas have acquired a specific character of their own.

In Old Delhi there is a strong feeling of *mohalla* ("neighbourhood"), partly induced by the peculiar housing layout. There gates or doorways open onto private residences and courtyards or onto *katrā* (one-room tenements facing a courtyard or other enclosure and having access to the street by only one opening or gate). The Civil Lines area consists of residences for upper income groups. The government housing areas also exhibit segregation by income groups. In some developed areas, "mixed neighbourhoods" have been created. Chānakyapuri (more commonly known as the Diplomatic Enclave), with its concentration of foreign embassies, represents a microcosm of international architecture. Cultural "islands" have formed in such areas as the Bengali Market area or Karol Bāgh; the latter, for example, is characterized variously by Bengali, South Indian, and Punjabi cultures, although cultural distinctiveness is being eroded as other city residents move in. Another facet of the city profile is the slum, inhabited mostly by construction workers, sweepers, factory labourers, and other low-income groups. There are also urban village enclaves, such as Kotla Mubārakpur, where houses and streets retain rural characteristics though residents have urban occupations.

Architecture. There is perhaps no city in India that can compare with Delhi in the number of its monuments. These edifices illustrate the types of Indian architecture from the time of the imperial Gupta dynasty 1,600 years ago to the period of British rule, when the style of such architects as Sir Edwin Lutyens and Sir Herbert Baker was in evidence in New Delhi. Delhi is particularly rich in material for the study of Indo-Muslim architecture. The monuments of the early Pashtun style (1193–1320)—represented by the Qūwat-ul-Islām mosque, the Quṭb Mīnar, the tomb of Iltutmish, and the 'Alā'ī Gate—reveal the adoption and adaptation of Hindu materials and style to Islāmic motifs and requirements. The later Pashtun styles represented in Tughlakābād and in the tombs of the Sayyid kings (1414–51) and Lodī kings (1451–1526) are characterized by finer domes and decoration and the use of finer marbles and tiles. The later Mughal architecture represented in the Red Fort (Lāl Qilāh) and the Principal Mosque (Jama Masjid) reveals an increasing use of marble, elaboration of external surfaces with florid decoration, and the construction of bulbous domes and lofty minarets.

Delhi's monuments

The Red Fort is one of the most important buildings of the city. Its massive red sandstone walls, 75 feet in height, enclose a complex of palaces, gardens, military barracks, and other buildings. The two most famous of these are the Hall of Public Audience (Dīvān-e 'Āmm) and the Hall of Private Audience (Dīvān-e Khāṣṣ). The Hall of Public Audience has 60 red sandstone pillars supporting a flat roof. The Hall of Private Audience is smaller and has a pavilion of white marble.

The architectural styles in the British period—represented by the Central Secretariat, Parliament House

W Suschitzky

The Principal Mosque (Jama Masjid) in Old Delhi.

(Sansad Bhavan), and the Presidential House (formerly the British viceroy's house)—combine the best features of the modern English school of architecture with traditional Indian forms. In the postindependence era, public buildings in Delhi began to show a utilitarian bias and a search for a synthesis of Indian and Western styles; the attempt, however, has not always been successful, as is evident from the Supreme Court building, the Science Building (a conference hall), and the government ministries. The Children's Building (a children's centre) and Rabindra Building (a fine arts centre) show a trend toward a new style, using modern materials. Along the Yamuna riverfront, memorials set in flowering gardens have been built for such 20th-century national leaders as Mahatma Gandhi (Rāj Ghat), Jawaharlal Nehru (Shānti Vana), and Lal Bahadur Shastri (Vijay Ghat).

THE PEOPLE

The refugee immigration

Delhi's population has increased dramatically from the 240,000 inhabitants it had in 1911. The highest growth rate occurred between 1941 and 1951—with the influx of refugees into the city at the time of independence—and population has also risen rapidly since 1990. Much of the increase is still from immigration. Population densities are among the highest of India's states and territories.

The composition of Delhi's population reflects its truly cosmopolitan character, with more than half of the residents coming from outside the territory. Most of these immigrants come from other Indian states and adjacent countries, and only a small proportion consists of resident foreigners. The religious composition of the population is also varied. The great majority of the population is Hindu; Muslims constitute the largest minority, followed by smaller numbers of Sikhs, Jains, Christians, and Buddhists.

THE ECONOMY

Delhi's service sector is the most important component of its economy and is the largest employer. The industrial sector is second and the commercial sector third. Agriculture once contributed significantly to the economy of the national capital territory but now is of little importance. A substantial proportion of Delhi's working population is engaged in various services, including public administration, the professions, the liberal arts, and various personal, domestic, and unskilled-labour services. As a trading and commercial centre, Delhi has held a dominant position in northern India for many centuries. In modern times it has also become a manufacturing centre and one of India's most important sources of export goods.

Industry. Traditionally, Delhi has been renowned for its artistic work, such as ivory carving and painting, gold and silver embroidery, decorative ware, copperware, and brassware. In modern times industry has diversified, and Delhi has become important for the manufacture of sophisticated products in small-scale industry, such as electronics and engineering goods, automobile parts, precision instruments, machinery, and electrical appliances. Wearing apparel, sports and leather goods, handloom products, and handicrafts are also produced. A large and thriving tourist sector has also developed.

Finance and trade. Delhi's position as the national capital and as a major industrial city have accentuated its function as a banking, wholesale-trade, and distribution centre. It is the headquarters of the Reserve Bank of India and of the regional offices of the State Bank and other banking institutions. It is also a divisional headquarters for the insurance business and an important stock-exchange centre. Delhi has long acted as a major distribution hub for much of northern India, handling a wide variety of items. Much of the distributive trade is carried on from within the Old Delhi area, where most of the markets are located near each other.

Transportation. The geographic position of Delhi on the great plain of India, where the Deccan tableland and the Thar Desert approach the Himalayas to produce a narrow corridor, ensures that all land routes from northwestern India to the eastern plain must pass through it, thus making it a pivotal centre in the subcontinent's network of transportation. Five national highways converge on Delhi. Several railway lines also meet there, linking the city with all parts of the country. Delhi is the most important air terminus in northern India for both domestic and international air services. Indira Gandhi International Airport, located in the southwestern part of the city, handles international flights. The nearby Pālam Airport is one of the hubs of the domestic airway system.

The traffic-circulation pattern within a city that was designed for a smaller population became heavily overburdened with Delhi's explosive growth. Improvements to the road system—such as adding overpasses and underpasses and widening major thoroughfares—have alleviated the worst traffic congestion, but the sheer volume of traffic—which includes such slow-moving vehicles as bullock carts, pedicabs, and bicycles—makes road travel in Delhi difficult, particularly during peak-hour conditions. Mass-transportation facilities are inadequate, the principal means of public transport consisting of buses. Long-distance commuting within the city is facilitated by Ring Road bus service and by the Ring Railway. The first sections of a planned 125-mile municipal rapid-transit system opened in 2002 and 2003.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Delhi was a chief commissioner's province when India attained independence in 1947. It became a centrally administered state in 1952, but in 1956 its status was changed to that of a union territory under the central government. Its designation was changed to the national capital territory in the early 1990s. A unified corporation for both urban and rural areas was established in 1958. The administrative system was further modified by the Delhi Administration Act of 1966. Under the present arrangement, Delhi has a three-tier administration consisting of a lieutenant governor and an executive council, an elected metropolitan council, and the municipal corporation. The lieutenant governor, appointed by the president of India, is the chief administrator of the territory and is assisted by an executive council of four members (headed by a chief executive councillor), who are also appointed by the president. The metropolitan council is a purely deliberative body. The municipal corporation is an elected local body having under its control most statutory autonomous bodies, notable exceptions being the New Delhi Municipal Committee, the Delhi Cantonment Board, and the Delhi Development Authority. The New Delhi Municipal Committee is a body nominated by the central government. The Delhi Cantonment Board consists of some elected and some nominated members, the latter with some ex officio members.

The administration

Housing. The housing situation in Delhi deteriorated after 1947 as a result of the influx of refugees caused by the partition of India and Pakistan and the city's emergence as the national capital of India. Since then, building activity has been insufficient to close the gap or to keep pace with the increasing population. This has compelled a large proportion of the city's population to seek shelter in congested areas and in unauthorized dwellings or to settle as squatters in slums.

The traditional houses in Old Delhi are unplanned, consisting of old structures of two, three, or more stories with a high proportion of single-room dwelling units. In the Civil Lines area there are a number of old one-story bungalows. In New Delhi the government housing colonies have been laid out in a lavish manner and are grouped by income.

A program to build new and rehabilitate old housing has been pushed since the 1950s; it is administered by a number of agencies, such as the government of the national capital territory, the various municipal governments, the Delhi Development Authority, and various individuals and cooperatives.

Public utilities. Water supply, drainage, sewerage, and conservancy and scavenging services are mandated functions of the municipal corporation. Such functions as city transportation and the generation and distribution of electricity, though not obligatory, are performed by the corporation. Three statutory agencies—the Delhi Water Supply and Sewage Disposal Undertaking, the Delhi Electric Sup-

The Central Secretariat in New Delhi.
Hubertus Kanus—Rapho/Photo Researchers

ply Undertaking, and the Delhi Transport Corporation—perform these functions.

Water supply

The supply of drinking water in Delhi has not kept up with demand, in spite of the fact that the water system has been improved and augmented several times. The Yamuna River, the main source of supply, is practically dry during the summer months. Underground water in the territory has generally been found to be brackish; Delhi, therefore, must depend for part of its needs upon the adjoining states.

Most of the residents of Delhi do not have access to adequate sewage disposal. Improvement is needed, both by way of extension of sewerage to new areas and by the expansion of its capacity in older areas. The treatment of sewage is also inadequate.

Delhi's electric power supply depends on power generated by local coal-burning thermal stations, augmented by sources outside the national capital territory. As with other utilities, the supply of power has always been distributed disproportionately.

Health and security. Overall health standards in Delhi exceed the national average, but the accessibility of health-care facilities varies widely. Much of the city's health care is provided by a large number of allopathic dispensaries, Āyurvedic and Unanī (*yūnānī*) dispensaries (*i.e.*, practicing indigenous systems of medicine that use mostly herbs and minerals), and homeopathic dispensaries. Most of the larger hospitals—such as the Dr. Ram Manohar Lohia Hospital, Smt. Sucheta Kripalani Hospital, and Lok Nayak J.P. Nārāyan Hospital—are administered by the national government or the Delhi administration.

The jurisdiction of the Delhi Fire Service extends over both the urban and rural areas of the national capital territory. In the rural areas, temporary stations are opened during the summer. The Delhi Police Service is under a commissioner of police of the Delhi administration. The city is divided into four police districts, each of which is under a superintendent of police.

Education. The growth of modern education in Delhi has kept pace with the expansion of the city's population. Primary-level education is nearly universal, and a large proportion of students also attend secondary school. Education for women at all levels has advanced at a much faster pace than it has for men. Among the institutions of higher learning, the most important is the University of Delhi, which has many affiliated colleges and research institutions. Among the major colleges for professional and other studies are the Indian Agricultural Research Institute, the Indian Institute of Technology, and the All India Institute of Medical Sciences.

CULTURAL LIFE

Delhi's cultural life has been influenced considerably by the cosmopolitan character of its population, which comes from different parts of India and the world and possesses varied cultural backgrounds. Much has been borrowed and adapted from Western culture, a process accelerated since independence by the influence of the modern mass media. Television, however, has also facilitated a greater awareness of regional and national interests. Although the cultural activities of earlier days—such as dancing, music, and poetry forums (*mushā'ira*)—have been yielding place to the cinema, the cabaret, and clubs, there are also theatre groups and institutions that have fostered indigenous literature and fine arts. Many of India's major cultural institutions—including the national academies of music, dance, and drama; of art; and of letters—are located in Delhi, as are numerous libraries, archives, and museums.

Delhi is home to numerous fairs and festivals. In addition to a variety of trade and book fairs, the city hosts an annual film festival. The many religious groups in Delhi contribute to an ongoing succession of religious festivals and celebrations.

Gardens

Delhi is a city of gardens and fountains, notable examples being the Roshan Āra Gardens and the meticulously planned and laid out Mughal Gardens. Many park and garden areas have grown up around historical monuments, such as the Lodī Gardens (around the Lodī Tombs) and the Firoz Shāh Kotla Grounds (around Aśoka's Pillar). Among the major recreation areas are the Delhi Ridge and the Yamuna riverfront. Delhi has well-developed sporting facilities, many of which were built when the city hosted the Asian Games in 1982.

History

The earliest reference to a settlement at Delhi is found in the epic *Mahābhārata* (a narrative about the descendants of the prince Bharata), which mentions a city called Indraprastha, built about 1400 BC under the direction of Yudhiṣṭhira, a Pāṇḍava king, on a huge mound somewhere between the sites where the historic Old Fort (Purāna Qilāh) and Humāyūn's Tomb were later to be located. Although nothing remains of Indraprastha, according to legend it was a thriving city. The first reference to the place-name Delhi, as already mentioned, seems to have

been made in the 1st century BC, when Rājā Dhilu built a city near the site of the future Quṭb Minar and named it for himself. Thereafter Delhi faced many vicissitudes and did not reemerge into prominence until the 12th century AD, when it became the capital of the Cauhān (Cāhamāna) ruler Pṛthvīrāja III. After the defeat of Pṛthvīrāja in the late 12th century, the city passed into Muslim hands. Quṭb-ud-Dīn Aybak, founder of the Mu'izzī (Slave) dynasty and builder of the famous tower Quṭb Minar (completed in the early 13th century), also chose Delhi as his capital.

'Alā'-ud-Dīn Khaljī (1296–1316) built the second city of Delhi at Siri, three miles northeast of the Quṭb Minar. The third city of Delhi was built by Ghiyāṣ-ud-Dīn Tughluq (1320–25) at Tughlakābād but had to be abandoned in favour of the old site near the Quṭb Minar because of a scarcity of water. His successor, Muḥammad ibn Tughluq, extended the city farther northeast and built new fortifications around it. It then became the fourth city of Delhi, under the name Jahānpanāh. These new settlements were located between the old cities near the Quṭb Minar and Siri Fort. Muḥammad ibn Tughluq's successor, Fīrūz Shāh Tughluq, abandoned this site altogether and in 1354 moved his capital farther north near the ancient site of Indraprastha and founded the fifth city of Delhi, Fīrūzābād, which was situated in what is now the Firoz Shāh Kotla area.

Invasion of Timur

After the invasion and sack of Delhi by Timur (Tamerlane) at the end of the 14th century, the last of the sultan kings moved the capital to Āgra, so that Delhi experienced a temporary diminution in its importance. Bābur, the first Mughal ruler, reestablished Delhi as the seat of his empire in 1526. His son Humāyūn built a new city, Dīn Panāh, on the site between Firoz Shāh Kotla and the Purāna Qal'ah. Shēr Shāh, who overthrew Humāyūn in 1540, razed Dīn Panāh to the ground and built his new capital, the Shēr Shāhī (Purāna Qal'ah), as the sixth city of Delhi.

Delhi later again lost importance when the Mughal emperors Akbar (1556–1605) and Jahāngīr (1605–27) moved their headquarters, respectively, to Fatehpur Sīkri and Āgra, but the city was restored to its former glory and prestige in 1638, when Shāh Jahān, Akbar's grandson, laid the foundations of the seventh city of Delhi, Shāhjahānābād, which has come to be known as Old Delhi. The greater part of the city is still confined within the space of Shāh Jahān's walls, and several gates built during his rule—the Kashmirī Gate, the Delhi Gate, the Turkman Gate, and the Ajmerī Gate—still stand.

With the fall of the Mughal Empire during the mid-18th century, Delhi again faced many vicissitudes—raids by the Marāthā (a people of peninsular India), the invasion by Nāder Shāh of Persia, and a brief spell of Marāthā rule—before the arrival of the British in 1803. Under British rule the city flourished, except during the Indian Mutiny in 1857, when the mutineers seized the city for several months, after which British power was restored and Mughal rule ended. In 1912 the British moved the capital of British India from Calcutta to the partially completed New Delhi, the construction of which was finished by 1931. (V.L.S.P.R./K.V.Su./V.R.)

The modern city

Since India's independence, Delhi has grown far beyond its original boundaries, spreading north and south along the Yamuna River, spilling onto the river's east bank, expanding over the Delhi ridge to the west, and, eventually, extending beyond the boundaries of the union territory into adjacent states. This increase was initially in response to the huge influx of Hindu refugees from Pakistan following partition, but since the early 1950s Delhi began absorbing immigrants from throughout India at an astounding rate. New Delhi, once adjacent to Delhi, is now a part of the larger city, as are the sites of the former seats of empire. Between ancient mausoleums and forts have sprouted high-rise towers, commercial complexes, and other aspects of the modern city.

This rapid development has not been without cost, however. In a pattern familiar to many postcolonial megalopolises, the huge influx of job-seeking immigrants placed a colossal strain on the city's infrastructure and on the ingenuity of city planners to provide sufficient power, sanitation, and clean water for the population. Most problematic, in a city in which the population had more than doubled since 1980, fully one-tenth of Delhi's residents lived in urban slums called *jhuggi-jhompris*; these lacked the most basic services and left city planners and administrators the difficult task of integrating more than a million slum-dwelling residents into a city whose infrastructure failed to accommodate already existing households.

Further, traffic congestion in Delhi has become among the worst in the world, a situation that contributed greatly to the city's already hazardous level of air pollution—this earned the Indian capital the dubious honour of being among the most polluted cities in the world. Antipollution measures undertaken since the 1980s have improved Delhi's air quality considerably, but overcrowding, congestion, and an overburdened infrastructure have remained as major obstacles for the city to overcome. Democracy

The term *democracy* literally means rule by the people. It is derived from the Greek *dēmokratiā*, which was coined from *dēmos* ("people") and *kratos* ("rule") in the middle of the 5th century BC to denote the political systems then existing in some Greek city-states, notably Athens.

The study of the history of democracy must consider two closely related topics. It is first of all concerned with the origins and development of democratic government, including the various forms such governments have taken throughout the world since the time of the ancient Greeks. It also encompasses the history of democratic ideas, including ideas about democracy's ultimate nature and value. This article will treat the history of democracy from both of these perspectives.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 541, 542, 543, 912, 10/51, and 10/52, and separate articles on individual political philosophers (*e.g.*, ARISTOTLE and LOCKE).

This article is divided into the following sections:

Fundamental questions

If a government of or by the people is to be established, at least five fundamental questions must be confronted at the outset, and two more are almost certain to be posed if the democracy continues to exist for long.

(1) What is the appropriate unit or association within which a democratic government should be established? A town or city? A country? A business corporation? A university? An international organization? All of these?

(2) Who among the members of the association should enjoy full citizenship? Which persons, in other words, should constitute the *dēmos*? Should the *dēmos* include all adults? If only a subset of adults are included, how small can the subset be before the association ceases to be a democracy and becomes something else, such as an aristocracy (government by the best, *aristos*) or an oligarchy (government by the few, *oligos*)?

The *dēmos*

(3) How are citizens to govern? What political organizations and institutions will they need?

(4) When citizens are divided on an issue, as they often will be, whose views should prevail, and in what circumstances? Should a majority always prevail, or should minorities sometimes be empowered to block or overcome majority rule?

(5) If a majority is ordinarily to prevail, what is to constitute a proper majority? A majority of all citizens? A majority of voters? Should a proper majority comprise not individual citizens but certain groups or associations of citizens, such as hereditary groups or territorial associations?

(6) Why should "the people" rule? Is democracy really better than aristocracy or monarchy? Perhaps, as Plato argues in the *Republic*, the best government would be led by a minority of the most highly qualified persons—an aristocracy of "philosopher-kings." What reasons could be given to show that Plato's view is wrong?

(7) Finally, what conditions favour the continued existence of democracy? What conditions are harmful to it? Why have some democracies managed to endure, even through periods of severe crisis, while so many others have collapsed?

The Granger Collection, New York

Democratic institutions

PREHISTORIC FORMS OF DEMOCRACY

Although it is often asserted that democracy was created in Greece about the year 500 BC, it is very likely that democratic government, in a broad sense, existed in several areas of the world well before this time. Forms of direct democracy probably existed among many tribal groups during the thousands of years when human beings survived by hunting and gathering. When humans began to settle in fixed communities for agriculture and trade, the conditions that favour popular participation in government seem to have become rare. Greater inequalities in wealth and military power between communities, together with a marked increase in the typical community's size, encouraged the spread of hierarchical and authoritarian forms of social organization. Popular governments among settled peoples vanished, to be replaced for thousands of years by monarchies, despotisms, aristocracies, and oligarchies.

CLASSICAL GREECE

During the Classical period (corresponding roughly to the 5th and 4th centuries BC), Greece was of course not a country in the modern sense but a collection of several hundred independent city-states, each with its surrounding countryside. In 507 the citizens of Athens began to develop a system of popular rule that would last nearly two centuries. Thus the Athenian answer to question 1 was that the political association most appropriate to democratic government is the polis, or city-state.

The Athenian answer to question 2—Who should constitute the *dēmos*—was similar to the answer developed in many newly democratic countries in the 19th and 20th centuries. Although citizenship in Athens was hereditary, extending to anyone who was born to parents who were

themselves Athenian citizens, membership in the *dēmos* was limited to male citizens 18 years of age or older (until 403, when the minimum age was raised to 20). One scholar has suggested that in the mid-4th century there were about 100,000 citizens, 10,000 resident foreigners, or metics, and as many as 150,000 slaves. Among citizens, about 30,000 were males over 18. If these numbers are roughly correct, then the *dēmos* comprised 10 to 15 percent of the total population.

The Athenian Assembly

Regarding question 3—What political institutions are necessary for governing?—the Athenians adopted an answer that would appear independently elsewhere. The heart and centre of their government was the Assembly (Ecclesia), which met on the Pnyx, a hill west of the Acropolis. Decisions were taken by vote, and, as in many later assemblies, voting was by a show of hands. The votes of a majority of those present and voting prevailed. The agenda of the Assembly was set by the Council of Five Hundred, which, unlike the Assembly, was composed of representatives chosen by lot from each of 139 small territorial entities, known as demes. The number of representatives from each deme was roughly proportional to its population.

Another important political institution in Athens was the popular courts (*dikasteria*), described by one scholar as having "unlimited power to control the Assembly, the Council, the magistrates, and political leaders." The popular courts were composed of jurors chosen by lot from a pool of citizens over 30 years of age; the pool itself was chosen annually and also by lot.

In 411 BC, exploiting the unrest created in Athens by the Peloponnesian War with Sparta, a group known as the Four Hundred seized control of Athens and established an oligarchy. Less than a year later, the Four Hundred were overthrown and democracy was restored. Nine decades later, in 321, Athens was subjugated by its northern neighbour Macedonia, which introduced property qualifications that effectively excluded many ordinary Athenians from the *dēmos*. In 146 BC what remained of Athenian democracy was extinguished by the conquering Romans.

THE ROMAN REPUBLIC

At about the same time that popular government was introduced in Greece, it also appeared on the Italian Peninsula in the city of Rome. The Romans called their system a *rēspublica,* or "republic," from the Latin *res*, meaning "thing" or "affair," and *publicus* or *publica*, meaning "public"—thus, a republic was the thing that belonged to the Roman people, the *populus romanus*.

Like Athens, Rome was originally a city-state. Although it expanded rapidly by conquest and annexation far beyond its original borders to encompass the entire Mediterranean world and much of western Europe, its government remained essentially that of a moderately large city-state. Indeed, throughout the republican era (until roughly the end of the 1st century BC), Roman assemblies were held in the very small Forum at the centre of the city.

Although Roman citizenship was conferred by birth, it was also granted by naturalization and by manumission of slaves. As the Roman Republic expanded, it conferred citizenship in varying degrees to many of those within its enlarged boundaries. Because Roman assemblies continued to meet in the Forum, most citizens who did not live in or near the city itself were effectively excluded from the *dēmos.*

The Romans created a political structure so complex that later democratic leaders chose not to emulate it. They used not only an extremely powerful Senate but also four assemblies, each called *comitia* ("assembly") or *concilium* ("council"). The Comitia Curiata was composed of 30 curiae, or local groups, drawn from three ancient *tribus*, or tribes; the Comitia Centuriata consisted of 193 centuries, or military units; the Concilium Plebis was drawn from the ranks of the plebes, or plebeians (common people); and the Comitia Tributa, like the Athenian Assembly, was open to all citizens. In all the assemblies, votes were counted by units (centuries or tribes) rather than by individuals.

Although they collectively represented all Roman citizens, the assemblies were not sovereign. Throughout the entire period of the republic, the Senate—an institution inherited from the earlier era of the Roman monarchy—continued to exercise great power. Senators were chosen indirectly by the Comitia Centuriata; during the monarchy, they were drawn exclusively from the privileged patrician class, though later, during the republic, members of certain plebeian families were also admitted.

THE ITALIAN REPUBLICS FROM THE 12TH CENTURY TO THE RENAISSANCE

"Constitutional oligarchies." After the western Roman Empire collapsed in 476, the Italian Peninsula broke up into a congeries of smaller political entities, some of which, about six centuries later, developed into more or less independent city-states. These city-states inaugurated systems of government based on wider—though not fully popular—participation and on the election of leaders for limited periods of time. Such governments flourished for two centuries or more in a number of cities, including Venice, Florence, Siena, and Pisa.

Drawing on Latin rather than Greek, the Italians called their city-states republics, not democracies. Membership in the *dēmos* was at first restricted mainly to the nobility and large landowners. In some republics in the first half of the 13th century, however, some groups from the lower social and economic classes—such as the newly rich, small merchants and bankers, and skilled craftsmen—began to demand the right to participate in government at some level. Because they were more numerous than the upper classes and because they threatened (and sometimes carried out) violent uprisings, some of these groups were successful. Even with these additions, however, the *dēmos* in the republics remained only a tiny fraction of the total population, ranging from 12 percent in 14th-century Bologna to 2 percent or less in 15th- and 16th-century Venice. Thus, whether judged by the standards of Classical Greece or those of Europe and the United States in the 18th century and later, the Italian republics were not democracies. A more accurate characterization, proposed by the historian Lauro Martines, is "constitutional oligarchies."

A democratic dilemma. The Greeks, the Romans, and the leaders of the Italian republics were pioneers in creating popular governments, and their philosophers and commentators exercised enormous influence on later political thought. Yet their political institutions were not emulated by the later founders of democratic governments in the nation-states of northern Europe and North America. As the expansion of Rome had already demonstrated, these institutions were simply not suited to political associations significantly larger than the city-state.

The enormous difference in size between a city-state and a nation-state indicates a fundamental dilemma. By limiting the size of a political association to that of a city-state, citizens can in principle ensure their capacity to influence directly the conduct of their government—*e.g.*, by participating in an assembly. But limiting size comes at a cost: important problems—notably defense and the regulation of trade and finance—will remain beyond the capacity of the government to deal with effectively. Alternatively, by increasing the size of the association—*i.e.*, by enlarging its geographic area and population—citizens can increase the capacity of the government to deal with important problems, but only at the cost of reducing their opportunities to influence the government directly through assemblies or other means.

Many city-states responded to this dilemma by forming alliances or confederations with other city-states and with larger political associations. But the problem would not finally be solved until the development of representative government, which first appeared in northern Europe in the 18th century.

TOWARD REPRESENTATIVE DEMOCRACY: EUROPE AND NORTH AMERICA TO THE 19TH CENTURY

Regional developments. *Continental Europe.* About AD 800, freemen and nobles in various parts of northern Continental Europe began to participate directly in local assemblies, to which were later added regional and national assemblies consisting of representatives, some or all

of whom came to be elected. In the mountain valleys of the Alps, such assemblies developed into self-governing cantons, leading eventually to the founding of the Swiss Confederation in the 13th century. By 900, local assemblies of Vikings were meeting in many areas of Scandinavia. Eventually the Vikings realized that to deal with certain larger problems they needed more-inclusive associations, and in Norway, Sweden, and Denmark regional assemblies developed. In 930 Viking descendants in Iceland created the first example of what today would be called a national assembly or parliament—the Althing.

England. Among the assemblies created in Europe during the Middle Ages, the one that most profoundly influenced the development of representative government was the English Parliament. Parliament grew out of councils that were called by kings for the purpose of redressing grievances and for exercising judicial functions. In time, it began to deal with important matters of state, notably the raising of revenues needed to support the policies of the monarch. As its judicial functions were increasingly delegated to courts, it gradually evolved into a legislative body. By the end of the 15th century, the English system displayed some of the basic features of modern parliamentary government: for example, the enactment of laws now required the passage of bills by both houses of Parliament and the formal approval of the monarch.

The English Parliament

By about 1800, significant powers, notably including powers related to the appointment and tenure of the prime minister, had shifted to Parliament. This development was strongly influenced by the emergence of political factions during the early years of the 18th century. These factions, known as Whigs and Tories, later became full-fledged parties. To king and Parliament alike it became increasingly apparent that laws could not be passed nor taxes raised without the support of a Whig or Tory leader who could muster a majority of votes in the House of Commons. To gain that support, the monarch was forced to select as prime minister the leader of the majority party in the Commons and to accept the leader's suggestions for the composition of the cabinet. By 1830 the constitutional principle that the choice of prime minister, and thus the cabinet, reposed with the House of Commons had become firmly entrenched in the (unwritten) British Constitution.

Parliamentary government in Britain was not yet a democratic system, however. Mainly because of property requirements, the franchise was held by only about 5 percent of the British population over 20 years of age. The Reform Act of 1832, which is generally viewed as a historic threshold in the development of parliamentary democracy in Britain, extended the suffrage to about 7 percent of the adult population. It would require further acts of Parliament in 1867, 1884, and 1918 to achieve universal male suffrage and one more law, enacted in 1928, to secure the right to vote for all adult women.

The United States. Whereas the feasibility of representative government was demonstrated by the development of Parliament, the possibility of joining representation with democracy first became fully evident in the governments of the British colonies of North America and later in the founding of the United States of America.

Conditions in colonial America favoured the limited development of a system of representation more broadly based than the one in use in Britain. These conditions included the vast distance from London, which forced the British government to grant significant autonomy to the colonies; the existence of colonial legislatures in which representatives in at least one house were elected by voters; the expansion of the suffrage, which in some colonies came to include most adult white males; the spread of property ownership, particularly in land; and the strengthening of beliefs in fundamental rights and popular sovereignty, including the belief that the colonists should not have to pay taxes to a government in which they were not represented ("no taxation without representation").

Because of the new country's large population and enormous size, democratic government was possible at the federal, state, and territorial levels only through representatives. In smaller associations, however, a direct assembly of citizens was both feasible and desirable. In many New England towns, for example, citizens assembled in meetings, Athenian style, to discuss and vote on local matters.

Thus, the United States provided new answers to question 1—What is the appropriate unit or association within which a democratic government should be established?—and question 3—How are citizens to govern? Yet, the American answer to question 2—Who should constitute the *dēmos?*—though radical in its time, was by later standards highly unsatisfactory. Even as the suffrage was broadly extended among adult white males, it continued to exclude large segments of the adult population, such as women, slaves, many freed blacks, and Native Americans.

Democracy or republic? Is *democracy* the most appropriate name for a large-scale representative system such as that of the early United States? At the end of the 18th century, the history of the terms whose literal meaning is "rule by the people"—*democracy* and *republic*—left the answer unclear. Both terms had been applied to the assembly-based systems of Greece and Rome, though neither assigned legislative powers to representatives elected by members of the *dēmos.* When the United States Constitutional Convention was held in 1787, terminology was still unsettled. Not only were *democracy* and *republic* used more or less interchangeably in the colonies, but no established term existed for a representative government "by the people."

Given the existing confusion over terminology, it is not surprising that the framers employed various terms to describe the novel government they proposed. In "Federalist 10," one of 85 essays by James Madison, Alexander Hamilton, and John Jay known collectively as the Federalist papers, Madison defined a "pure democracy" as "a society consisting of a small number of citizens, who assemble and administer the government in person," and a republic as "a government in which the scheme of representation takes place." Thus, for Madison *democracy* meant direct democracy, and *republic* meant representative government.

"Federalist 10"

In November 1787, James Wilson, one of the signers of the Declaration of Independence, proposed a new classification. He wrote,

> [T]he three species of governments are the monarchical, aristocratical and democratical. In a monarchy, the supreme power is vested in a single person: in an aristocracy . . . by a body not formed upon the principle of representation, but enjoying their station by descent, or election among themselves, or in right of some personal or territorial qualifications; and lastly, in a democracy, it is inherent in a people, and is exercised by themselves or their representatives.

At the Virginia ratifying convention some months later, John Marshall, the future chief justice of the Supreme Court, declared that the "Constitution provided for 'a well regulated democracy' where no king, or president, could undermine representative government." The political party that he organized in cooperation with Thomas Jefferson, the future third president of the United States, was named the Democratic-Republican Party; the party adopted its present name, the Democratic Party, in 1844.

Following his visit to the United States in 1831–32, the French political scientist Alexis de Tocqueville asserted in no uncertain terms that the country he had observed was a democracy—indeed, the world's first representative democracy, where the fundamental principle of government was "the sovereignty of the people." Tocqueville's estimation of the American system reached a wide audience in Europe and beyond through his monumental four-volume study *Democracy in America* (1835–40).

Solving the dilemma. Thus, by the end of the 18th century both the idea and the practice of democracy had been profoundly transformed. Political theorists and statesmen now recognized that the nondemocratic practice of representation could be used to make democracy practicable in the large nation-states of the modern era. Representation, in other words, was the solution to the ancient dilemma between enhancing the ability of political associations to deal with large-scale problems and preserving the opportunity of citizens to participate in government.

To some of those steeped in the older tradition, the union of representation and democracy seemed a marvelous and

epochal invention. In the early 19th century the French author Destutt de Tracy, the inventor of the term *idéologie* ("ideology"), insisted that representation had rendered obsolete the doctrines of both Montesquieu and Jean-Jacques Rousseau, both of whom had denied that representative governments could be genuinely democratic. In 1820 the English philosopher James Mill proclaimed "the system of representation" to be "the grand discovery of modern times" in which "the solution of all the difficulties, both speculative and practical, will perhaps be found." One generation later Mill's son, the philosopher John Stuart Mill, concluded in his *Considerations on Representative Government* (1861) that "the ideal type of a perfect government" would be both democratic and representative.

New answers to old questions. *Suffrage.* In the 19th and 20th centuries there were important changes in the prevailing answers to some of the other fundamental questions mentioned earlier. One important development concerned question 2—Who should constitute the *dēmos?* In the 19th century, property requirements for voting were reduced and finally removed. The exclusion of women from the *dēmos* was increasingly challenged—not least by women themselves. Beginning with New Zealand in 1893, more and more countries granted women the suffrage and other political rights, and by the mid-20th century women were full and equal members of the *dēmos* in almost all countries that considered themselves democratic.

Although the United States granted women the right to vote in 1920, another important exclusion continued for almost half a century: African Americans were prevented, by both legal and illegal means, from voting and other forms of political activity, primarily in the South but also in other areas of the country. Not until after the passage and enforcement of the Civil Rights Act of 1964 were they effectively admitted into the American *dēmos.* Native Americans suffered similar forms of discrimination.

The Civil Rights Act

Thus, in the 19th and 20th centuries the *dēmos* was gradually expanded to include all adult citizens. By the mid-20th century, no system whose *dēmos* did not include all adult citizens could properly be called democratic.

Factions and parties. In many of the city-state democracies and republics, part of the answer to question 3—What political institutions are necessary for governing?—consisted of factions, including both informal groups and organized political parties. Much later, representative democracies in several countries developed political parties for selecting candidates for parliament and for organizing parliamentary support for (or opposition to) the prime minister and his cabinet. Nevertheless, at the end of the 18th century leading political theorists continued to regard factions as a profound danger to democracies and republics. This view was also common at the United States Constitutional Convention.

Factions are dangerous, it was argued, for at least two reasons. First, a faction is by definition a group whose interests are in conflict with the general good. Second, historical experience shows that, prior to the 18th century, the existence of factions in a democracy or republic tended to undermine the stability of its government. The "instability, injustice, and confusion introduced into the public councils" by factionalism, Madison wrote, have been "the mortal diseases under which popular governments have everywhere perished."

Interestingly, Madison used the presumed danger of factions as an argument in favour of adopting the new constitution. Because the United States, in comparison with previous republics, would have many more citizens and vastly more territory, the diversity of interests among its population would be much greater, making the formation of large or powerful factions less likely. Similarly, the exercise of government power by representatives rather than directly by the people would "refine and enlarge the public views, by passing them through the medium of a chosen body of citizens, whose wisdom may best discern the true interest of their country."

Madison eventually abandoned his belief in the essential perniciousness of factions. Political parties, he came to believe, were not only legally possible, necessary, and inevitable—they were also desirable. They were legally possible because of the rights and liberties provided for in the constitution. They were necessary in order to defeat the Federalists, whose centralizing policies Madison, Jefferson, and many others strongly opposed. Because parties were both possible and necessary, they would inevitably be created. Finally, parties were also desirable, because, by helping to mobilize voters throughout the country and in the legislative body, they enabled the majority to prevail over the opposition of a minority.

This view came to be shared by political thinkers in other countries in which democratic forms of government were developing. By the end of the 19th century, it was nearly universally accepted that the existence of independent and competitive political parties is an elementary standard that every democracy must meet.

Majority rule, minority rights, majority tyranny. The fear of "majority tyranny" was a common theme in the 17th century and later, even among those who were sympathetic to democracy. Given the opportunity, it was argued, a majority would surely trample on the fundamental rights of minorities. Property rights were perceived as particularly vulnerable, since presumably any majority of citizens with little or no property would be tempted to infringe the rights of the propertied minority. Such concerns were shared by Madison and other delegates at the Convention—including Benjamin Franklin, who once observed that "democracy is two wolves and a lamb voting on what to have for lunch."

The fear of majority tyranny was eased and finally abandoned after democratic leaders, including Madison himself, realized that unrestrained majority rule could be blocked by numerous legal barriers, none of which would be clearly inconsistent with basic democratic principles. Thus, a bill of rights could be incorporated into the constitution; a supermajority of votes could be required for constitutional amendments and other important kinds of legislation; the executive, legislative, and judicial powers of government could be divided into separate branches; and an independent judiciary could be given the power to declare laws or policies unconstitutional.

Although political theorists continue to disagree about the best means to effect majority rule in democratic systems, it is evident that majorities cannot legitimately abridge the fundamental rights of citizens. In short, because democracy is not only a political system of "rule by the people" but necessarily also a system of rights, a government that infringes these rights is to that extent undemocratic.

Democracy as a system of rights

THE SPREAD OF DEMOCRACY IN THE 20TH CENTURY

During the 20th century, the number of countries possessing the basic political institutions of representative democracy increased significantly. At the beginning of the 21st century, more than one-third of the world's nominally independent countries possessed democratic institutions comparable to those of the English-speaking countries and the older democracies of Continental Europe. In an additional one-sixth of the world's countries, these institutions, though somewhat defective, nevertheless provided historically high levels of democratic government. What accounted for this rapid expansion of democracy?

Failures of nondemocratic systems. A significant part of the explanation is that all the main alternatives to democracy—whether of ancient or of modern origins—suffered political, economic, diplomatic, and military failures that greatly lessened their appeal. With the victory of the Allies in World War I, the ancient systems of monarchy, aristocracy, and oligarchy ceased to be legitimate. Following the military defeat of Italy and Germany in World War II, the newer alternative of fascism was likewise discredited, as was Soviet-style communism after the economic and political collapse of the Soviet Union in 1990–91. Similar failures contributed to the gradual disappearance of military dictatorships in Latin America in the 1980s and '90s.

Market economies. Accompanying these ideological and institutional changes were changes in economic institutions. Highly centralized economies under state control had enabled political leaders to use their access to economic resources to reward their allies and punish their critics. As these systems were displaced by more decentralized

market economies, the power and influence of top government officials declined. In addition, some of the conditions that were essential to the successful functioning of market economies also contributed to the development of democracy: access to reliable information, relatively high levels of education, ease of personal movement, and the rule of law. As market economies expanded and as middle classes grew larger and more influential, popular support for such conditions increased, often accompanied by demands for further democratization.

Correlation of democracy and prosperity

Economic well-being. As the economic well-being of large segments of the world's population gradually improved, so too did the likelihood that newly established democratic institutions would survive and flourish. In general, citizens in democratic countries with persistent poverty are more susceptible to the appeals of antidemocratic demagogues who promise simple and immediate solutions to their country's economic problems. Accordingly, widespread economic prosperity in a country greatly increases the chances that democratic government will succeed.

Political culture. During the 20th century, democracy continued to exist in some countries despite periods of acute diplomatic, military, economic, or political crisis, such as occurred during the early years of the Great Depression. The survival of democratic institutions in these countries is attributable in part to the existence in their societies of a culture of widely shared democratic beliefs and values. In countries where democratic culture is weak or absent, such as the Weimar Republic of Germany in the years following World War I, democracy is much more vulnerable, and periods of crisis are more likely to lead to a reversion to a nondemocratic regime.

CONTEMPORARY DEMOCRATIC SYSTEMS

Differences among democratic countries in historical experience, size, ethnic and religious composition, and other factors have resulted in significant differences in their political institutions. Political scientists have used these differences to identify a few basic kinds of democratic political system.

Presidential and parliamentary systems. Whereas versions of the U.S. presidential system were frequently adopted in Latin America, Africa, and elsewhere in the developing world, as European countries democratized, they adopted versions of the English parliamentary system, which made use of both a prime minister responsible to parliament and a ceremonial head of state, who may be a hereditary monarch—as in the Scandinavian countries, The Netherlands, and Spain—or a president chosen by parliament—as in Israel. A notable exception is France, which in its fifth constitution, adopted in 1958, combined its parliamentary system with a presidential one.

Unitary and federal systems. In most older European and English-speaking democracies, political authority inheres in the central government, which is constitutionally authorized to determine the limited powers, as well as the geographic boundaries, of subnational associations such as states and regions. Such unitary systems contrast markedly with federal systems, in which authority is constitutionally divided between the central government and the governments of relatively autonomous subnational entities. Democratic countries that have adopted federal systems include—in addition to the United States—Switzerland, Germany, Austria, Spain, Canada, and Australia. The world's most populous democratic country, India, also has a federal system.

Proportional and winner-take-all systems. Electoral arrangements vary enormously. Some democratic countries divide their territories into electoral districts, each of which is entitled to a single seat in the legislature, the seat being won by the candidate who gains the most votes—hence the terms *first past the post* in Britain and *winner take all* in the United States. As critics of this system point out, in districts contested by more than two candidates, it is possible to gain the seat with less than a strict majority of votes (50 percent plus one). As a result, a party that receives only a minority of votes in the entire country could win a majority of seats in the legislature. Systems of proportional representation are designed to ensure a closer correspondence between the proportion of votes cast for a party and the proportion of seats it receives. With few exceptions, Continental European countries have adopted some form of proportional representation, as have Ireland, Australia, New Zealand, and Japan. Winner-take-all systems remain in the United States, Canada, and, for parliamentary elections, Britain.

Two-party and multiparty systems. Because proportional representation does not favour large parties over smaller ones, as does the winner-take-all system, in countries with proportional representation there are almost always three or more parties represented in the legislature, and a coalition government consisting of two or more parties is ordinarily necessary to win legislative support for the government's policies. Thus the prevalence of proportional representation effectively ensures that coalition governments are the rule in democratic countries; governments consisting of only two parties, such as that of the United States, are extremely rare.

Majoritarian and consensual systems. Because of differences in electoral systems and other factors, democratic countries differ with respect to whether laws and policies can be enacted by a single, relatively cohesive party with a legislative majority, as is ordinarily the case in Britain and Japan, or instead require consensus among several parties with diverse views, as in Switzerland, The Netherlands, Sweden, Italy, and elsewhere. Political scientists and others disagree about which of the two types of system, majoritarian or consensual, is more desirable. Critics of consensual systems argue that they allow a minority of citizens to veto policies they dislike and that they make the tasks of forming governments and passing legislation excessively difficult. Supporters contend that consensual arrangements produce comparatively wider public support for government policies and even help to increase the legitimacy and perceived value of democracy itself.

The theory of democracy

DEMOCRATIC IDEAS FROM PERICLES TO RAWLS

The "theory of democracy" refers to the study of the nature and ultimate value of democracy, an endeavour that is both empirical and philosophical. Not surprisingly, the first important contributions to the theory of democracy were made by the ancient Greeks, and particularly by political leaders and philosophers of Athens.

"The school of Hellas"

Pericles. In a funeral oration in 430 BC for those who had fallen in the Peloponnesian War, the Athenian leader Pericles described democratic Athens as "the school of Hellas." Among the city's many exemplary qualities, he declared, was its constitution, which "favors the many instead of the few; this is why it is called a democracy." Pericles continued: "If we look to the laws, they afford equal justice to all in their private differences; if to social standing, advancement in public life falls to reputation for capacity, class considerations not being allowed to interfere with merit; nor again does poverty bar the way; if a man is able to serve the state, he is not hindered by obscurity of his condition. The freedom which we enjoy in our government extends also to our ordinary life."

Aristotle. A century later, Aristotle discussed democracy in terms that would become highly influential in comparative studies of political systems. At the heart of his approach is the notion of a "constitution." Aristotle identifies three kinds of ideal constitution—each of which describes a situation in which those who rule pursue the common good—and three corresponding kinds of perverted constitution—each of which describes a situation in which those who rule pursue narrow and selfish goals. The three kinds of constitution, both ideal and perverted, are differentiated by the number of persons they allow to rule. Thus "rule by one" is monarchy in its ideal form and tyranny in its perverted form; "rule by the few" is aristocracy in its ideal form and oligarchy in its perverted form; and "rule by the many" is "polity" in its ideal form and democracy in its perverted form.

Aristotle's general scheme prevailed for more than two millennia, though his unsympathetic and puzzling definition of democracy did not.

Locke. Nearly 20 centuries after Aristotle, the English philosopher John Locke adopted the essential elements of the Aristotelian classification of constitutions in his *Second Treatise of Civil Government* (1690). Unlike Aristotle, however, Locke was an unequivocal supporter of political equality, individual liberty, democracy, and majority rule. Although his work was naturally rather abstract and not particularly programmatic, it provided a powerful philosophical foundation for much later democratic theorizing and political programs.

The legitimacy of government. According to Locke, in the hypothetical "state of nature" that precedes the creation of human societies, men live "equal one amongst another without subordination or subjection," and they are perfectly free to act and to dispose of their possessions as they see fit, within the bounds of natural law. From these and other premises Locke draws the conclusion that political society—*i.e.*, government—insofar as it is legitimate, represents a social contract among those who have "consented to make one Community or Government . . . wherein the Majority have a right to act and conclude the rest." These two ideas—the consent of the governed and majority rule—became central to all subsequent theories of democracy. For Locke they are inextricably connected: no government is legitimate unless it enjoys the consent of the governed, and that consent cannot be rendered except through majority rule.

Locke differentiates the various forms of government on the basis of where the people choose to place the power to make laws. If the people retain the legislative power for themselves, together with the power to appoint those who execute the laws, then "the Form of the Government is a perfect Democracy." If they put the power "into the hands of a few select Men, and their Heirs or Successors, . . . then it is an Oligarchy: Or else into the hands of one Man, and then it is a Monarchy." Although it relies on the traditional categories, Locke's analysis is far more subversive of nondemocratic forms of government than it appears to be. For whatever the form of government, the ultimate source of sovereign power is the people, and all legitimate government must rest on their consent. Therefore, if a government abuses its trust and violates the people's fundamental rights—particularly the right to property—the people are entitled to rebel and replace that government with another to whose laws they can willingly give their consent. Moreover, it is the people themselves who are entitled to judge whether the government has abused its trust. Although he does not use the term, Locke thus unambiguously affirms the right of revolution against a despotic government.

The Declaration of Independence

Less than a century later, Locke's views were echoed in the famous words of the United States Declaration of Independence:

> We hold these truths to be self-evident, that all men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty, and the pursuit of Happiness. That to secure these rights, Governments are instituted among Men, deriving their just powers from the consent of the governed, that whenever any Form of Government becomes destructive of these ends, it is the Right of the People to alter or abolish it . . . .

Answers to fundamental questions. Although Locke's ideas were radical in his time, his answers to questions 1 through 3 would need further elaboration, and even some alteration, as the theory and practice of democracy continued to develop.

Regarding question 1—What is the appropriate association within which a democratic government should be established?—Locke clearly intended his conclusions to apply to England as a whole and presumably also to other nation-states. Departing from views that still prevailed among political philosophers of his time, Locke held that democracy did not require a small political unit, such as a city-state, in which all members of the *dēmos* could participate in government directly.

Regarding question 2—Who should constitute the *dēmos*?—Locke believed, along with almost everyone else who had expressed an opinion on the issue, that children should not enjoy the full rights of citizenship, though he maintained that parents are morally obliged to respect their children's rights as human beings. With almost no substantive argument, Locke also adopted the traditional view that women should be excluded from the *dēmos*, though he insisted that they retain all other fundamental rights.

Unlike the men of Athens or the small male aristocracy of Venice, obviously the men of England could not govern themselves directly in an assembly. In this case, then, the answer to question 3—What political institutions are necessary for governing?—would have to include the use of representatives chosen by the people. Yet Locke provided little guidance as to the form a representative government might take.

Montesquieu. The French political theorist Montesquieu, through his masterpiece *The Spirit of the Laws* (1748), strongly influenced his younger contemporary Rousseau and many of the American Founding Fathers, including John Adams, Jefferson, and Madison. Rejecting Aristotle's classification, Montesquieu distinguishes three ideal types of government: monarchy, "in which a single person governs by fixed and established laws"; despotism, "in which a single person directs everything by his own will and caprice"; and republican (or popular) government, which may be of two types, depending on whether "the body, or only a part of the people, is possessed of the supreme power," the former being a democracy, the latter an aristocracy.

According to Montesquieu, a necessary condition for the existence of a republican government, whether democratic or aristocratic, is that the people in whom supreme power is lodged possess the quality of "public virtue," meaning that they are motivated by a desire to achieve the public good. Although public virtue may not be necessary in a monarchy and is certainly absent in despotic regimes, it must be present to some degree in aristocratic republics and to a large degree in democratic republics. Sounding a theme that would be loudly echoed in Madison's "Federalist 10," Montesquieu asserts that without strong public virtue, a democratic republic is likely to be destroyed by conflict between various "factions," each pursuing its own narrow interests at the expense of the broader public good.

Hume. The destructive power of factions was also emphasized by the Scottish philosopher David Hume, whose influence on Madison was perhaps even greater than Montesquieu's. For it was from Hume that Madison seems to have acquired a view about factions that turned the issue of the desirability of larger political associations—*i.e.*, those larger than the city-state—on its head. For the purpose of diminishing the destructive potential of factionalism, so Hume and Madison argued, bigger is in fact better, because in bigger associations each representative must look after a greater diversity of interests.

Rousseau. When compared with Locke, Jean-Jacques Rousseau sometimes seems the more radical democrat, though a close reading of his work shows that, in important respects, Rousseau's conception of democracy is narrower than Locke's. Indeed, in his most influential work of political philosophy, *The Social Contract* (1762), Rousseau asserts that democracy is incompatible with representative institutions, a position that renders it all but irrelevant to nation-states. The sovereignty of the people, he argues, can be neither alienated nor represented. But if representation is incompatible with democracy, and if direct democracy is the only legitimate form of government, then no nation-state of Rousseau's time or any other can have a legitimate government. Furthermore, according to Rousseau, if a political association that is small enough to practice direct democracy, such as a city-state, were to come into existence, it would inevitably be subjugated by larger nation-states and thereby cease to be democratic.

The Social Contract

For these and other reasons, Rousseau was pessimistic about the prospects of democracy. Adopting a view common among critics of democracy in his time, Rousseau also held that "there is no government so subject to civil wars and intestine agitations as democratic or popular government." In a much-cited passage, he declares that, "were there a people of gods, their government would be democratic. So perfect a government is not for men."

Mill. In his work *On Liberty* (1859) John Stuart Mill ar-

gued on utilitarian grounds that individual liberty cannot be legitimately infringed—whether by government, society, or individuals—except in cases where the individual's action would cause harm to others. This principle provided a philosophical foundation for some of the basic freedoms essential to a democracy—such as freedom of association—and undermined the legitimacy of paternalistic laws—such as those requiring temperance—which in Mill's view treated adult citizens like children. In the area of what he called the liberty of thought and discussion, another freedom crucial to democracy, Mill argued, also on utilitarian grounds, that legal restrictions on the expression of opinion are never justified. The "collision of adverse opinions," he contended, is a necessary part of any society's search for the truth. In another work, *Considerations on Representative Government* (1861), Mill set forth in a lucid and penetrating manner many of the essential features of the new type of government, which had not yet emerged in Continental Europe and was still incomplete in important respects in the United States. In this work he also advanced a powerful argument on behalf of woman suffrage—a position that virtually all previous political philosophers (all of whom were male) had ignored or rejected.

Dewey. According to the American philosopher John Dewey, democracy is the most desirable form of government because it alone provides the kinds of freedom necessary for individual self-development and growth—the freedom to exchange ideas and opinions, the freedom to form associations to pursue common goals, and the freedom to determine and pursue one's own conception of the "good life." Democracy is more than a form of government, however; as Dewey remarks in *Democracy and Education* (1916), it is also a "mode of associated life" in which citizens cooperate with each other to solve their common problems through rational means in a spirit of mutual respect and good will. Moreover, the political institutions of any democracy, according to Dewey, should not be viewed as the perfect and unchangeable creations of visionary statesmen of the past; rather, they should be constantly subject to criticism and improvement as historical circumstances and the public interest change.

Democracy and Education

Participation in a democracy as Dewey conceived it requires critical and inquisitive habits of mind, an inclination toward cooperation, and a feeling of public spiritedness and a desire to achieve the common good. Because these habits and inclinations must be inculcated from a young age, Dewey placed great emphasis on education. His contributions to both the theory and practice of education were enormously influential in the United States in the 20th century.

Dewey offered few concrete proposals regarding the form that democratic institutions should take. Nevertheless, in *The Public and Its Problems* (1927) and other works, he contended that individuals cannot develop to their fullest potential except in a social democracy, or a democratic welfare-state. Accordingly, he held that democracies should possess strong regulatory powers. He also insisted that among the most important features of a social democracy should be the right of workers to participate directly in the management of the firms in which they are employed.

Rawls. From the time of Mill until about the mid-20th century, most philosophers who defended democratic principles did so largely on utilitarian grounds—*i.e.*, they argued that systems of government that are democratic in character are more likely than other systems to produce a greater amount of happiness (or well-being) for a greater number of people. Such justifications, however, were traditionally vulnerable to the objection that they could be used to support forms of government in which the greater happiness of the majority is achieved by unfairly neglecting the rights and interests of a minority.

In *A Theory of Justice* (1971), the American philosopher John Rawls attempted to develop a nonutilitarian justification of a democratic political order characterized by fairness, equality, and individual rights. Reviving the notion of a social contract, which had been dormant since the 18th century, he imagined a hypothetical situation in which a group of rational individuals are rendered ignorant of all social and economic facts about themselves—including facts about their race, sex, religion, education, intelligence, talents or skills, and even their conception of the good life—and then asked to decide what general principles should govern the political institutions under which they live. From behind this "veil of ignorance," Rawls argues, such a group would unanimously reject utilitarian principles—such as "political institutions should aim to maximize the happiness of the greatest number"—because no member of the group could know whether he belonged to a minority whose rights and interests might be neglected under institutions justified on utilitarian grounds.

The "veil of ignorance"

Instead, reason and self-interest would lead the group to adopt principles such as the following: (1) Everyone should have a maximum and equal degree of liberty, including all the liberties traditionally associated with democracy. (2) Everyone should have an equal opportunity to seek offices and positions that offer greater rewards of wealth, power, status, or other social goods. (3) The distribution of wealth in society should be such that those who are least well-off are better off than they would be under any other distribution, whether equal or unequal. (Rawls holds that some inequality in the distribution of wealth may be necessary to achieve higher levels of productivity. It is therefore possible to imagine unequal distributions of wealth in which those who are least well-off are better off than they would be under an equal distribution.) These three principles amount to an egalitarian form of democratic liberalism. Rawls is accordingly regarded as the leading philosophical defender of the modern democratic capitalist welfare state.

THE VALUE OF DEMOCRACY

Why should "the people" rule? Is democracy really superior to any other form of government? Although a full exploration of this issue is beyond the scope of this article, history—particularly 20th-century history—demonstrates that democracy uniquely possesses a number of features that most people, whatever their basic political beliefs, would consider desirable: (1) Democracy helps to prevent rule by cruel and vicious autocrats. (2) Modern representative democracies do not fight wars with one another. (3) Countries with democratic governments tend to be more prosperous than countries with nondemocratic governments. (4) Democracy tends to foster human development—as measured by health, education, personal income, and other indicators—more fully than other forms of government do.

Other features of democracy also would be considered desirable by most people, though some would regard them as less important than features 1 through 4 above: (5) Democracy helps people to protect their fundamental interests. (6) Democracy guarantees its citizens fundamental rights that nondemocratic systems do not, and cannot, grant. (7) Democracy ensures its citizens a broader range of personal freedoms than other forms of government do.

Finally, there are some features of democracy that some people—the critics of democracy—would not consider desirable at all, though most people, upon reflection, would regard them as at least worthwhile: (8) Only democracy provides people with a maximum opportunity to live under laws of their own choosing. (9) Only democracy provides people with a maximum opportunity to take moral responsibility for their choices and decisions about government policies. (10) Only in a democracy can there be a relatively high level of political equality.

These advantages notwithstanding, there have been critics of democracy since ancient times. Perhaps the most enduring of their charges is that most people are incapable of participating in government in a meaningful or competent way because they lack the necessary knowledge, intelligence, wisdom, experience, or character. According to Plato, for example, the best government would be an aristocracy of philosopher-kings whose rigorous intellectual and moral training would make them uniquely qualified to rule. The view that the people as a whole are incapable of governing themselves has been espoused not only by kings and aristocratic rulers but also by political theorists (Plato

Criticisms of democracy

foremost among them), religious leaders, and other authorities. The view was prevalent in one form or another throughout the world during most of recorded history until the early 20th century.

No doubt there will be critics of democracy for as long as democratic governments exist. The extent of their success in winning adherents and promoting the creation of nondemocratic regimes will depend on how well democratic governments meet the new challenges and crises that are all but certain to occur.

Problems and challenges

At the beginning of the 21st century, democracy faced a number of challenges, some of which had been problems of long standing, others of which were more recent.

INEQUALITY OF RESOURCES

Although market economies encouraged the spread of democracy, in countries where they were not sufficiently regulated such economies eventually produced large inequalities in economic and social resources, from wealth and income to education and social status. Because those with greater resources naturally tended to use them to influence the political system to their advantage, the existence of such inequalities constituted a persistent obstacle to the achievement of a satisfactory level of political equality.

IMMIGRATION

After World War II, immigration to the countries of western Europe, Australia, and the United States, both legal and illegal, increased dramatically. Differences in language, culture, and appearance between immigrant groups and the citizens of the host country, as well as the usually widespread perception that immigrants take jobs away from citizens and use expensive social services, made immigration a hotly debated issue in many countries. In some instances, anti-immigrant sentiment contributed to the rise of radical political parties and movements, some of which promoted racist or neofascist doctrines that were hostile not only to immigrants but also to fundamental political and human rights and even to democracy itself.

TERRORISM

Acts of terrorism committed within democratic countries or against their interests in other parts of the world occurred with increasing frequency beginning in the 1970s. In response to such events, democratic governments adopted various measures designed to enhance the ability of police and other law-enforcement agencies to protect their countries against terrorism. Some of these initiatives entailed new restrictions on citizens' civil and political liberties and were accordingly criticized as unconstitutional or otherwise inconsistent with democratic principles. In the early 21st century it remained to be seen whether democratic governments could strike a satisfactory balance between the sometimes conflicting imperatives of ensuring security and preserving democracy.

INTERNATIONAL SYSTEMS

At the end of the 18th century, in response to the dilemma of size described earlier, the focus of both the theory and the practice of democracy shifted from the small association of the city-state to the far larger nation-state. Although their increased size enabled democracies to solve more of the problems they confronted, there remained some problems that not even the largest democracy could solve by itself. To address these problems several international organizations were established after World War II, most notably the United Nations (1945), and their numbers and responsibilities grew rapidly through the rest of the 20th century.

The United Nations

These organizations posed two related challenges to democracy. First, by shifting ultimate control of a country's policies in a certain area to the international level, they reduced to a corresponding extent the influence that citizens could exert on such policies through democratic means. Second, all international organizations, even those that were formally accountable to national governments, lacked the political institutions of representative democracy. How could these institutions be made democratic—or at least more democratic?

TRANSITION, CONSOLIDATION, BREAKDOWN

The problems and challenges facing democracy were particularly acute in countries that became democratic in the late 20th and early 21st centuries. Obstacles in the path of a successful consolidation of democratic institutions include economic problems such as widespread poverty, unemployment, massive inequalities in income and wealth, rapid inflation, and low or negative rates of economic growth. Countries at low levels of economic development also usually lack a large middle class and a well-educated population. In many of these countries, the division of the population into antagonistic ethnic, racial, religious, or linguistic groups has made it difficult to manage political differences peacefully. In others, extensive government intervention in the economy, along with other factors, has resulted in the widespread corruption of government officials. Many countries also lack an effective legal system, making civil rights highly insecure and allowing for abuse by political elites and criminal elements. In these countries the idea of the rule of law is not well established in the prevailing political culture, and in other respects the political culture of these countries does not inculcate in citizens the kinds of beliefs and values that could support democratic institutions and practices during crises or even during the ordinary conflicts of political life.

In light of these circumstances, it is quite possible that the extraordinary pace of democratization begun in the 20th century will not continue long into the 21st century. Nevertheless, the odds are great that in the foreseeable future a very large share of the world's population, in a very large share of the world's countries, will live under democratic forms of government that continue to evolve in order to meet challenges both old and new.

BIBLIOGRAPHY

Democratic institutions. A concise introduction is ALAN F. HATTERSLEY, *A Short History of Democracy* (1930). Historical and theoretical approaches are combined in JOHN DUNN (ed.), *Democracy: The Unfinished Journey, 508 BC to AD 1993* (1992, reprinted with corrections 1993); and SANFORD LAKOFF, *Democracy: History, Theory, and Practice* (1996). General works on ancient Greece include I.E.S. EDWARDS *et al.* (eds.), *The Cambridge Ancient History*, 3rd ed., 14 vol. (1970–2000); and THOMAS R. MARTIN, *Ancient Greece: From Prehistoric Times to Hellenistic Times*, updated ed. (2000). A.H.M. JONES, *Athenian Democracy* (1957, reissued 1986), is indispensable. The most comprehensive study of democracy in Athens is MOGENS HERMAN HANSEN, *The Athenian Democracy in the Age of Demosthenes*, trans. from the Danish by J.A. CROOK (1991, reissued 1999). A brief account of Rome's republican government is F.E. ADCOCK, *Roman Political Ideas and Practice* (1959, reissued 1972). An excellent, though critical, account of the Italian city-state republics is LAURO MARTINES, *Power and Imagination: City-States in Renaissance Italy* (1979, reissued 2002). An essential source on the development of cabinet government in Britain is ARCHIBALD S. FOORD, *His Majesty's Opposition, 1714–1830* (1964, reissued 1979).

The theory of democracy. The theory, foundations, and institutions of democracy are described in ROBERT A. DAHL, *Democracy and Its Critics* (1989, reissued 1991), and *On Democracy* (1998, reissued 2001); and IAN SHAPIRO, *Democracy's Place* (1996).

Problems and challenges. Contemporary problems and challenges are discussed in IAN SHAPIRO and CASIANO HACKER-CORDÓN (eds.), *Democracy's Edges* (1999); KEITH DOWDING, JAMES HUGHES, and HELEN MARGETTS (eds.), *Challenges to Democracy* (2001); and SERGIO FABBRINI (ed.), *Nation, Federalism and Democracy* (2001). Some implications of democratic ideas for nongovernmental organizations are examined in ROBERT A. DAHL, *A Preface to Economic Democracy* (1985); and IAN SHAPIRO, *Democratic Justice* (1999, reissued 2001).

(R.A.Da.)

Denmark

Located strategically at the mouth of the Baltic Sea, the Kingdom of Denmark (Kongeriget Danmark) occupies the peninsula of Jutland (Jylland) and an archipelago of more than 400 islands. Of the country's total land area of 16,639 square miles (43,094 square kilometres), the largest part, 11,497 square miles, is Jutland; the largest of the islands (excluding distant Greenland) are Zealand (Sjælland; 2,876 square miles) and Funen (Fyn; 1,152 square miles). The nation's capital, Copenhagen (København), is located on Zealand; the second largest city, Århus, is the major urban centre of Jutland.

Denmark is attached directly to continental Europe at Jutland's 42-mile (68-kilometre) boundary with Germany. Other than this connection, all the frontiers of Denmark with surrounding nations are maritime, including that with Great Britain to the west across the North Sea. Norway and Sweden lie to the north, separated from Denmark by sea lanes linking the North Sea to the Baltic Sea by way of passages called (from west to east) the Skagerrak, the Kattegat, and The Sound (Øresund). Eastward in the Baltic Sea lies the Danish island of Bornholm.

Though small in territory and population, Denmark has nonetheless played a notable role in European history. In prehistoric times, Danes and other Scandinavians reconfigured European society when the Vikings undertook marauding, trading, and colonizing expeditions. During the Middle Ages, the Danish crown dominated northwestern Europe through the power of the Kalmar Union. In later centuries, shaped by geographic conditions favouring maritime industries, Denmark established trading alliances throughout northern and western Europe and beyond, particularly with Great Britain and the United States. As an important contribution to world culture, Denmark developed humane governmental institutions and cooperative, nonviolent approaches to problem solving.

The Kingdom of Denmark is more than just the land of the Danes. Two remote island worlds in the Atlantic Ocean became integral parts of the Danish state when their colonial status was transformed by full incorporation into the Danish nation. One is the Faroe (Faeroe) Islands, which support a distinctive language and culture. The most remote part of the kingdom is Greenland, an 840,000-square-mile Arctic wilderness, mostly covered by ice, that is the ancestral homeland of scattered coastal communities of Inuit-speaking Greenlanders (also known as Inuit or Eskimos) who formerly lived by hunting and fishing. Many contemporary inhabitants of Greenland are of mixed Danish and aboriginal ancestry. Home rule was granted to the Faroes in 1948 and to Greenland in 1979, though foreign policy and defense remain under Danish control. Each area is distinctive in history, language, and culture.

This article covers the land and people of continental Denmark. For a discussion of its dependent states, see the *Micropædia* articles GREENLAND and FAROE ISLANDS.

The article is divided into the following sections:

Physical and human geography

THE LAND

The basic contours of the Danish landscape were shaped at the end of the Pleistocene Epoch by the last glaciation of the Ice Age, the so-called Weichsel glaciation. This great glacial mass withdrew temporarily during several warmer interstadial periods, but it repeatedly returned to cover the land until it retreated to the Arctic north for the last time about 10,000 years ago. As a result, the barren layers of chalk and limestone that earlier constituted the land surface acquired a covering of soil that built up as the Weichsel retreated, forming low, hilly moraines that diversify the otherwise flat landscape.

Relief. Denmark proper is a lowland area that lies, on average, not more than 100 feet (30 metres) above sea level. The country's highest point, reaching only 568 feet (173 metres), is Yding Forest Hill in east-central Jutland.

A scenic boundary representing the extreme limit reached by the Scandinavian and Baltic ice sheets runs from Nissum Fjord on the western coast of Jutland eastward toward Viborg, from there swinging sharply south down the spine

The ice front

of the peninsula toward Åbenrå and the German city of Flensburg, just beyond the Danish frontier. The ice front is clearly marked in the contrast between the flat western Jutland region, composed of sands and gravels strewn by meltwaters that poured west from the shrinking ice sheet, and the fertile loam plains and hills of eastern and northern Denmark, which become markedly sandier toward the prehistoric ice front.

In northern Jutland, where the long Lim Fjord separates the northern tip from the rest of the peninsula, there are numerous flat areas of sand and gravel, some of which became stagnant bogs. Burials and ritual deposits interred in these bogs in antiquity—especially during the Bronze and Iron ages—have been recovered by archeologists. In more recent centuries, these bogs were a valued source of peat for fuel. In the 20th century, they have been drained to serve as grazing areas for livestock.

In places along the northern and southwestern coasts of Jutland, salt marshes were formed by evaporation of an inland sea that existed during the Late Permian epoch (approximately 258 to 245 million years ago). Senonian chalk, deposited about 100 million years ago, is exposed in southeastern Zealand, at the base of Stevn Cliff and Møn Cliff, and at Bulbjerg, in northwestern Jutland. Younger Danian limestone (about 65 million years old) is extensively quarried in southeastern Zealand.

On Bornholm, outcroppings reveal close affinities with geologic formations in southern Sweden. Precambrian granites more than 570 million years old—among the oldest on the Earth's surface—are exposed across extensive areas on the northern half of the island. On the southern half, Cambrian sandstone and shales overlie the older granites.

Drainage and soils. The longest river in Denmark is the Gudenå. It flows a distance of 98 miles from its source just northwest of Tørring, in east-central Jutland, through the Silkeborg Lakes and then northeast to empty in the Randers Fjord on the east coast. There are many small lakes; the largest is Arre on Zealand, with a surface area of 15.7 square miles. Large lagoons have formed behind

the coastal dunes in the west, such as at the Ringkøbing and Nissum fjords.

In most of Denmark, the soil rests on glacially deposited gravel, sand, and clay, under which lie ancient chalk and limestone. The subterranean limestone resulted in permeation of the soil with calcium that diminished its value for agriculture when it was first brought under cultivation in the Neolithic era. Through millennia of cultivation, however, the soil improved greatly, so that 60 percent of the land surface is excellent for farming.

Climate. Denmark experiences changeable weather because it is located in the temperate zone at the meeting point of diverse air masses from the Atlantic, the Arctic, and eastern Europe. The west coast faces the inhospitable North Sea, but the terminal section of the warm Gulf Stream (the North Atlantic Drift) moderates the climate.

Influence of the Gulf Stream

The cold, rainy winters produce frozen lakes and snow-covered fields, yet they are moderated by the influence of the Gulf Stream. The mean temperature in February, the coldest month, is 32° F (0° C), which is 12° F (7° C) higher than the worldwide average for that latitude. The number of days when freezing weather occurs ranges annually from 70 on the west coast to 120 in the interior. Summers are mild, featuring episodes of cloudy weather interrupted by sunny days. The mean temperature in July, which is the warmest month, is 61° F (16° C).

Rain falls throughout the year but is relatively light in winter and spring and greatest from late summer to early winter. The annual precipitation of 25 inches (635 millimetres) ranges from about 32 inches in southwestern Jutland to about 16 inches in parts of the archipelago.

Plant and animal life. In prehistoric times, before fields were cleared for cultivation, much of the land was covered with a deciduous forest of oak, elm, lime (linden), and beech trees. The original forest did not survive, but highly valued areas were reforested later to break up the expanses of agricultural fields that dominate the landscape. Denmark borders the coniferous belt and has therefore been receptive to the establishment of plantations of spruce and fir, particularly in parts of Jutland where extensive wastelands of dune vegetation and heather were reclaimed for forestry. In all, about 10 percent of the land is forested.

Abundant postglacial herds of large mammals, including elk, aurochs, brown bear, and wild boar, died out under the pressures of human expansion and an intensive agricultural system. Roe deer, however, still occupy the countryside, and the large-antlered red deer can be found in the forests of Jutland. Smaller animals such as hares and hedgehogs have also survived. Birds are abundant, numbering more than 300 species, of which about half breed in the country. Storks—common summer residents in the early 20th century—migrate each year from their winter home in Africa, but they are now rare. Fish are abundant in Danish waters, particularly cod, herring, and plaice, which form the basis for a large fishing industry.

Settlement patterns. Agriculturalists established a village settlement pattern early in the prehistory of Denmark.

Open-field system

From at least the Middle Ages until the 18th century, these settlements were organized under the rules of an open-field system, the dominant feature of which was communalism. Most individual landholders were tenant farmers (*fæstebønder*) whose farm buildings and land belonged to the local manor house (*herregård*). The scattered plots of tenanted land were located in each of two or three large fields, which were farmed collectively by the tenants; therefore, it was essential that villagers agree on the nature and timing of plowing, harrowing, planting, and harvesting. Meeting at a central place in the village, family heads discussed common problems of field management and agreed on mutual responsibilities and cooperation. Each family received harvests from its own plots but worked with the others to manage the fields. They shared resources in order to assemble large wheeled plows, each drawn by six or eight horses. Livestock were grazed as a single village herd on the stubble of harvested fields. Shared decisions were also made on the use of communal facilities such as the meadow, commons, village square, pond, and church. Danish peasants cooperated in much of what they did, and a communal spirit was the product.

Farms surrounding the town of Nørreby, Fem Island, Denmark.
Erik Betting/Pressehuset

The open-field system was replaced by the consolidation of fields (*udskiftningen*) and the purchase of farms (*frikøbet*) as a result of the great land reforms (*De store langboreformer*) put into place by reform-minded estate owners. By the beginning of the 19th century, the wheeled plow had been replaced by a lightweight plow that could be pulled by a single horse, which most farmers could afford. The bulk of the economy shifted from subsistence to commercial farming. The result was dismantlement of the old open-field system and an end to village communalism. As small scattered plots were consolidated into larger individual holdings, some landowners moved their farmsteads away from the village to be closer to their fields, obscuring the pattern of village settlements. Parts of western Jutland were late to be brought under cultivation. Poor soil resulting from postglacial geologic conditions discouraged farmers from settling in these areas until population pressure made them more attractive.

The nation is no longer overwhelmingly rural. An economic shift to light industry and trade was associated with a growth in the size of towns and cities. In the late 20th century the movement to cities continued but was no longer primarily to major centres. Migration to smaller urban centres grew disproportionately, and migrants to urban areas settled more commonly in suburban residential communities than in the cities as such. With modern roads and railway transportation, in a land in which distances are not great, the isolation of farms and villages has ended.

THE PEOPLE

Ethnic composition. Denmark is almost entirely inhabited by ethnic Danes. Very few Faeroese or Greenlanders have settled in continental Denmark, despite their status as Danish citizens. Small German, Jewish, and Polish minorities, on the other hand, have been long established and are substantially assimilated. In the 1960s an economic expansion required more labour than the nation could supply, and "guest workers" (*gæstearbejdere*) made their way into Denmark. In the late 1980s the most numerous ethnic minorities in Denmark were Turks, Yugoslavs, Iranians, and Pakistanis.

"Guest workers"

Linguistic composition. Danish is the official language. It is closely related to Norwegian, with which it is mutually intelligible, especially in the written form. Although the other Scandinavian languages (excepting Finnish) are close relatives, they are sufficiently different to be understood easily only by those schooled or experienced in the effort. Many educated or urban Danes have learned to speak a second language. English has replaced German as the most popular foreign language.

Religions. Religious freedom is an unchallenged value

in Denmark. Roman Catholic churches and Jewish synagogues have long existed in the larger cities. About 90 percent of all Danes, however, are at least nominally members of the state Evangelical Lutheran church (*folkekirken*), which replaced Roman Catholicism as the official religion after the Lutheran Reformation in 1536.

"Grundtvigianism" designates a revitalization movement that inspired a new sense of Christian awareness in the 19th century at a time when Danish Protestantism had become very formal and ritualistic. N.F.S. Grundtvig provided a philosophical, religious, and organizational basis for "educating and awakening" the impoverished peasantry. This was achieved by establishing folk high schools in which Christian belief and peasant culture were taught as a basis for creating pride in the Danish heritage.

The Home Mission

A revival movement within the framework of the Danish church was also organized in the 19th century. Known as the Home Mission (Indremissionen), it was founded by a clergyman, Vilhelm Beck. The Home Mission survives as a contemporary evangelical expression of Pietism, which had won converts in the 18th century. Members of the Home Mission constitute a minority within the church; they place emphasis on the importance of individual Bible study, personal faith, and a sin-free style of living.

Demographic trends. For many years the net population total has just barely maintained itself. The total fertility rate (average number of births for each childbearing woman) is only 1.4. A nearly universal acceptance of the concept of population control, in combination with emigration to the United States and elsewhere, has effectively restrained growth. Because losses in reproductive replacement and emigration have been offset by slight increases from immigration, the population remained nearly stable at 5.1 million during the late 20th century. The age distribution has shifted as a consequence of a lower level of fertility. There are now relatively fewer persons in the under-20 age group and more in the over-80 age group.

THE ECONOMY

Denmark supports a high standard of living with well-developed social services. It boasts a per capita gross national product that is one of the highest in the world. The economy is based primarily on service industries, trade, and manufacturing; only 6 percent of the population is engaged in agriculture, fishing, and forestry. Small enterprises are dominant.

The only Nordic country to do so, Denmark joined the European Economic Community in 1973, at the same time as the United Kingdom, then its most important trading partner. At the same time, economic collaboration among the Nordic countries continues. No passports are required for travel by Scandinavians within the region, and communication among the various agencies of government is direct and need not be channeled through their respective embassies. Scandinavians enjoy a common labour market that includes reciprocal social welfare benefits and the right to vote in local elections in the neighbouring country of residence. There is capital mobility, supported by the Nordic Investment Bank. Uniform legislation, particularly with regard to commercial law, dates to the 19th century.

In the Danish mixed welfare-state economy, private sector expenditures account for more than half of the net national income. Public expenditure is directed to education, national defense, social services, and agricultural subsidies. The government neither owns capital nor has significant commercial or industrial income. Public income is primarily derived from taxes on real estate, personal income, and capital and through customs and excise duties. The heaviest indirect tax, which goes to the national government, is the value-added tax (VAT).

Both employers and employees are well organized. Membership in unions is normally based upon the particular skills of the workers. The association of employees is called the National Confederation of Trade Unions (Landsorganisationen); the principal association of employers is the Danish Confederation of Employers (Dansk Arbejdsgiverforeningen).

Resources. Danish natural resources are quite limited. During the early 1970s the economy suffered from dependence on imported petroleum for more than 90 percent of its energy needs. Finds of oil and natural gas fields in the Danish sector of the North Sea permitted a partial self-sufficiency in this regard. Coal-fired power plants produce 90 percent of the nation's electricity, up from 10 percent in 1970. The switch from petroleum was accompanied by economies of production in which otherwise wasted heat from the production of electricity is used to heat water that is piped to homes and factories. By this means, the energy output of power plants has been doubled.

Agriculture and fishing. A new spirit of communalism among farmers emerged with the massive social changes at the end of the 19th century, a time of poverty and economic depression. When cereal prices fell, Danish farmers fought for survival by using their crops as fodder to produce butter, eggs, and bacon. They succeeded by establishing folk high schools as well as agricultural and dairy cooperatives. The result was a peasantry that was literate, well motivated, and competitive in the marketplace. The producer cooperatives disbanded after 1950, however, and folk high schools have lost their central importance.

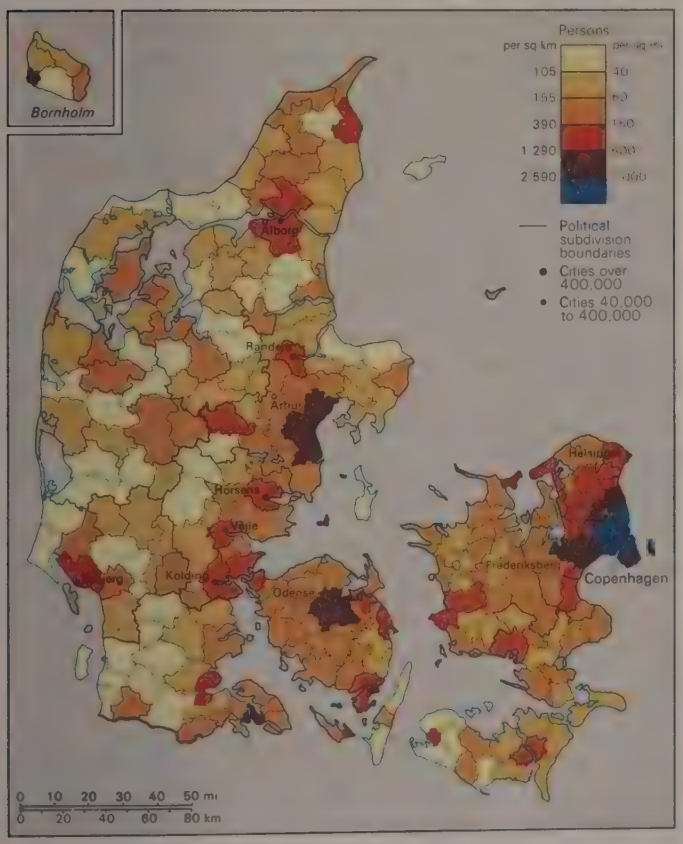
Next to its well-educated labour force, the soil is still Denmark's most important raw material. About 60 percent of the land is intensively exploited and extensively fertilized. More than half of the cultivated land is devoted to cereals, with barley and wheat accounting for a large percentage of the total grain harvest. Sugar beets are another leading crop. Oats, rye, turnips, and potatoes are grown in western Jutland, where the soil is less fertile.

Major crops

Domesticated animals are an important feature of life in Denmark. Dairy cattle, pigs, and poultry are raised in great numbers to supply both the domestic and the foreign markets.

Farms are generally small or medium-sized family-owned enterprises. The extensive fertilization and application of scientific animal husbandry helps to maintain the viability of small farm operations. Milk and dairy products, pork, and eggs account for a major percentage of the total value of production. Fur farming, especially of minks and foxes, is economically important.

The fishing industry is still economically important. Her-



Population density of Denmark.

ring, cod, and plaice (or flatfish) account for more than 90 percent of the total catch; other important species include salmon, eel, and deepwater shrimp. Danish commercial fishing also extends into foreign waters in search of Atlantic cod, Norwegian pout, and North Sea sprat (brisling).

Industry. Denmark has a small extractive industry that relies on granite (for roads and housing) and kaolin (for ceramics and paper manufacture) found on Bornholm. Local boulder clays are molded and baked to make bricks and tiles. Moler (marine diatomaceous earth) is mined for use in insulating materials for the building industry, and white chalk is essential for the manufacture of cement.

The largest employers are the manufacturers of metal products, machinery, and equipment; the food processing industry; the paper and graphic industries; and manufacturers of transport equipment. The production of footwear, clothing, wood and wood products, furniture, and electronic equipment also provide substantial employment.

Finance and trade. In 1846, the first commercial bank was established in Denmark. In 1975, commercial and savings banks became equal in status, and foreign banks, which theretofore had maintained representative offices in Copenhagen, were permitted to establish full branches. All banks are under government supervision, and public representation is required on their supervisory boards.

The banking system

The National Bank of Denmark (Danmarks Nationalbanken) is the only bank of issue and enjoys a special status as a self-governing institution under government supervision. Profits revert to the state treasury. The national stock exchange, established in 1861, is located in Copenhagen.

Imports of raw materials and fuel formerly were balanced largely by exports of agricultural products, supplemented by income from shipping and tourism. In the late 20th century the overseas trade pattern shifted to a major reliance on the export of industrial products, including industrial machinery, electronic equipment, and chemical products. Agricultural products such as fish, poultry, dairy products, meat, beer, and furs are still important exports, however. Denmark has created an export market for household furniture, toys, silverware, ceramics, plastics, textiles, clothing, and other goods notable for their creative modern design.

As a member of the EEC (since 1993, the European Community [EC]), Denmark relies heavily upon foreign trade within Europe. Germany, the United Kingdom, and Sweden provide the largest markets for both agricultural products and manufactured goods.

Transportation. An extensive road and highway system serves the nation. The number of private automobiles in use has risen rapidly since World War II. Bicycles, once a common mode of transport, are still popular. Cities and towns maintain bicycle lanes located parallel to motor roads and sidewalks.

Bus and coach routes extend throughout the country, including some operated by the Danish State Railways and others organized regionally by local government authorities. A comparatively large railroad network was established during the last half of the 19th century.

Characteristic features of the Danish transportation system are the ferries and many bridges. Of particular importance are the bridge and tunnel systems that connect Zealand with Funen (via the small island of Sprogø) and Copenhagen with Malmö, Swed. (opened 1997–98 and 2000, respectively). Several bridges also connect Funen and Jutland. Many good harbours provide favourable conditions for both domestic and international shipping.

Kastrup, near Copenhagen, is one of the busiest airports in Europe. In addition to internal flights, the airport at Kastrup is a centre for international air traffic. The Scandinavian Airlines System (SAS), a joint Danish-Norwegian-Swedish enterprise, flies European and intercontinental routes. Danair, owned by SAS, operates regular services between Copenhagen and other cities on Zealand, Jutland, Funen, Bornholm, and the Faroe Islands.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. The constitution of June 5, 1953, provides for a unicameral legislature, the Folketing, with 179 members (including two from the Faroe Islands and two from Greenland). The prime minister heads the government, which is composed additionally of cabinet ministers who run the various departments, such as justice, finance, and agriculture. The monarch signs acts passed by the Folketing upon the recommendation of the cabinet sitting as a Council of State. To become law, the acts must also be countersigned by at least one cabinet member. Faced with a vote of no confidence, the cabinet must resign.

The constitution of 1953

In addition to establishing unicameralism, the 1953 constitution mandates popular referenda (used, for example, to secure public approval for Danish entry into the EEC) and postulates the creation of an ombudsman office—the first outside Sweden, its country of origin. The Succession to the Throne Act, which accompanied the 1953 constitution, provides for female succession. This allowed the accession of Queen Margrethe II in 1972.

Denmark is divided into 13 counties and 271 municipalities. It has universal adult suffrage by voluntary and secret ballot, with a voting age of 18 for both national and local elections. All voters are eligible to run for office. The voter turnout in national elections approaches 90 percent. Elections are held on the basis of proportional representation, in which each political party gains seats in the Folketing, or in the city council, in proportion to its strength among the voters. As a result the national government is usually composed of a coalition of parties that does not enjoy a majority, and the government must piece together a majority for each item of legislation. Members of the Folketing are elected to a four-year term, but the prime minister may dissolve the legislature and call for new elections at any time. Despite the splintering of parties, Denmark has enjoyed stable government, with new elections on an average of once every three years.

Political parties

The largest Danish political party, the Social Democratic Party, led most Danish governments from the 1930s to the early 1980s; since then, coalition governments have predominated, including those of nonsocialist parties headed by the Conservative People's Party and the Liberal Party in 1981–93. All of Denmark's political parties support the continuation of the welfare state, except for the tax-protest Progress Party, which also expresses anti-immigration sentiments. The Christian People's Party criticizes the laws that liberalize abortion and decriminalize pornography. The Socialist People's Party is against Denmark's affiliation with NATO and is part of the movement that opposes Danish membership in the European Union (EU).

Justice. Minor infractions in Denmark are tried in the police courts. Most other criminal charges and civil disputes fall within the jurisdiction of the 84 municipal courts. Two High Courts hear appeals from the municipal courts and serve as courts of original jurisdiction in serious criminal cases, in which 12-person juries are impaneled. In some nonjury criminal cases, lay judges sit alongside professional judges and have an equal vote. A special Court of Complaints may reopen a criminal case and order a new trial. In Copenhagen there is a Maritime and Commercial Court, which also uses lay judges. The Supreme Court sits at the apex of the legal system.

Education. Education in Denmark is free, and virtually the entire adult population is literate. Nine years of school attendance for children 7 to 16 years of age is compulsory. Preschool and kindergarten education is optional, but about 60 percent of children between the ages of 5 and 6 years attend kindergarten classes.

After reaching the 9th grade, almost one-fourth of all students leave school to enter the workforce, approximately half go on for additional vocational education, and somewhat more than one-fourth continue on to matriculate either in an upper secondary school (*gymnasium*) or in another institution offering a higher preparatory education. While many graduates of the gymnasium enter the workforce, others continue on to the university or to schools and academies of university rank that specialize in technical and artistic fields. Children from the highest socioeconomic class have a greater probability of continuing higher education than do others. The enrollment of men and women is essentially equal.

At the pinnacle of higher education are the University of

Higher education

Copenhagen (founded in 1479), the University of Aarhus (1928), and the University of Odense (1964), all state-supported. In addition, university centres were established at Roskilde in 1970 and Ålborg in 1974.

Health and welfare. Danes on the whole enjoy excellent health. Aggressive public health programs are directed against the threats of infectious diseases. Public health nurses provide free advice and assistance to mothers, which, with good nutrition and housing, has contributed to a low infant mortality rate. More than 80 percent of the cost of the health care system is paid for by national and local authorities and employers. Life expectancy at birth is about 72 years for males and about 78 years for females.

Danish citizens may choose between two primary health care options. Most Danes opt for completely free care that is provided by a general practitioner; some, however, prefer to pay about one-third of their medical bills out of pocket for the privilege of choosing any family physician or specialist they wish.

A national old-age pension scheme is available for all persons 67 years of age and older, with basic amounts being paid irrespective of the financial position of the beneficiary. A disability pension and a pension for widows 55 years of age or older are also in effect.

According to the Danish constitution, "Any person unable to support himself or his dependants shall, where no other person is responsible for his or their maintenance, be entitled to receive public assistance." The state welfare programs of Denmark should not be thought of as institutionalized charity, however. Health, education, unemployment, disability, and old-age benefits are available at virtually no charge to all Danes. They are recognized both legally and in public opinion as morally just social rights that have been paid for by taxes and assessments.

CULTURAL LIFE

Daily life. Danes traditionally faced life from the security of the nuclear family, as has been true throughout Europe. During the late 20th century, substantial changes have taken place. For example, marriage is no longer entered into by young adults as an almost inevitable social institution. Historically, the Danes easily tolerated sexual relations between individuals who were engaged to be married. In earlier centuries it was not uncommon for marriage to take place after a baby was born, although it was considered immoral and unacceptable not to marry eventually. Now, the inevitability of marriage has fallen away. Cohabitation without the formalities of engagement and wedding is common. Nearly one-fifth of all unions in Denmark are by cohabitation rather than formal marriage. Consistent with the decline of contracted marriages, the incidence of divorce has risen. One marriage in four may be expected to end in dissolution.

Forty percent of live births now take place out of wedlock, as compared with only 10 percent a generation ago. These children are not necessarily raised by single parents, however. Children are born to approximately 40 percent of consensual unions, and two children or more are found in 15 percent of such relationships. The changes in marriage and divorce statistics and the growing incidence of consensual unions are primarily due to the changed role of women in society. Women have experienced greater independence as well as increased responsibility for economic survival and child care. They are educated on a more equal basis with men, and they participate more equally in the job market, although not yet with equal pay. The availability of contraceptive methods and free abortions has also increased women's options. In the mid-1960s slightly fewer than 50 percent of married women between the ages of 20 and 50 engaged in paid employment. Twenty years later more than 80 percent of married women were working. The ability to earn their own incomes has made marriage less necessary for women to provide security for themselves and their children. It has also made divorce less punitive in socioeconomic terms.

Status of women

The arts and sciences. Although the Danes are few in population, they have been numerous in contributing to the growth of world civilization. Tycho Brahe (1546–1601) was a major figure in the early telescopic exploration of the universe; Thomas Bartholin (1616–80) was the first anatomist to describe the human lymphatic system; Nicolaus Steno (1638–86) established geology as a science; Ole Rømer (1644–1710) measured the speed of light for the first time; Caspar Thomeson Bartholin, Jr. (1655–1738) discovered the ductus sublingualis major and the glandula vestibularis major, both of which bear his name as Bartholin's duct and gland; Hans Christian Ørsted (1777–1851) discovered electromagnetism; Niels Finsen (1860–1904) won the Nobel Prize for Physiology or Medicine for his work on the medical uses of ultraviolet rays, and Johanes Fibiger (1867–1928) won the same award for his research on cancer; Valdemar Poulsen (1869–1942) developed a device for generating radio waves; Niels Bohr (1885–1962) won the Nobel Prize for Physics for his achievements in quantum physics, a prize which was later won by his son, Aage Bohr; and Carl Peter Henrik Dam (1895–1976) won the Nobel Prize for Physiology or Medicine for the discovery of vitamin K.

Saxo Grammaticus (d. 1204) contributed a book of history, *Gesta Danorum*, to world literature; Rasmus Rask (1787–1832) founded comparative philology; N.F.S. Grundtvig (1783–1872) founded a theological movement and pioneered in education relating to human rights; Søren Kierkegaard (1813–55) helped to shape existentialist philosophy; Bertel Thorvaldsen (1770?–1844) achieved renown as a sculptor in a neoclassic style; Hans Christian Andersen (1805–75) authored fairy tales that are read throughout the world; Carl Nielsen (1865–1931) composed classical music of international fame; Carl T. Dreyer (1889–1968), a film director, is respected internationally; Jørn Utzon won world recognition as the architect of the Sydney Opera House; and Karen Blixen (1885–1962) achieved world acclaim writing under the name of Isak Dinesen. The Nobel Prize for Literature was awarded to the novelist Henrik Pontoppidan (1857–1943) in 1917 and to Johannes V. Jensen (1873–1950), whose works included the novel *The Long Journey* (*Den lange rejse*), in 1944.

Cultural institutions. The first Danish-speaking theatre was opened in Copenhagen in 1722, followed in 1748 by The Royal Theatre (*Det Kongelige Teater*), which remained under court patronage for a century. In 1848 it was taken over by the state and is now administered by the Ministry for Cultural Affairs. Besides a relatively large number of classical and modern Danish plays, the repertoire includes much that is current in Britain, the United States, Germany, and France.

Ballet and theatre

A resident ballet company, which also performs in The Royal Theatre, was founded more than 200 years ago, but only through its youngest generation of dancers in the style of choreographer August Bournonville has it become internationally acclaimed as the Royal Danish Ballet.

Denmark supports 10 symphony orchestras; two of the more important are the Danish Radio Symphony Orchestra and the Royal Orchestra. Musicians and singers are trained at the Royal Danish Conservatory in Copenhagen and other conservatories and at the Opera Academy.

The Royal Danish Academy of Fine Arts was established in 1754. It produced Bertel Thorvaldsen and, in the 20th century, the sculptor Robert Jacobsen and the architects Arne Jacobsen and Kaj Gottlob. Famous craft concerns include the firm of Georg Jensen, silversmith, the Royal Copenhagen and Bing and Grøndahl porcelain factories, the glassworks of Holmegård and Kastrup, and the furniture manufacturer Fritz Hansens Eftf.

Recreation. The pursuit of sport became popular after defeat in the Danish-German war of 1863–64 as Danes turned to an interest in small arms and physical training. Soon every part of Denmark had established shooting, gymnastics, and athletic clubs. Soccer was introduced to Denmark by British engineers who came to design the railroad system in the 1870s. Rowing was organized at a national level as early as 1886, making the Copenhagen Rowing Club (established in 1865) the oldest sports club in the world. Soccer, or association football, became an organized sport when the Copenhagen Ball Club was established in 1876, and soccer remains a national sport. At various times Danish athletes have won Olympic gold medals in canoeing, shooting, swimming, rowing, and

cycling events. These and many other sports appeal to sports-minded Danes, particularly in the summer months, and no Dane is immune to the attractions of a visit to one of the many well-tended parks, forests, or beaches that honeycomb the nation.

Press and broadcasting. Radio Denmark offers Danish programming, but in most parts of Denmark it is also possible to receive strong radio signals from neighbouring nations, particularly Sweden in the north and Germany in the south. State-managed television broadcasting is mainly devoted to current affairs, cultural events, and programs of interest to children and young people. The owners of radio and television sets pay an annual license fee, which finances broadcasting operations and frees the main radio and television stations from the interruptions of commercial advertising. A second television channel and some radio transmission is funded partly by commercials.

Complete freedom of the press is guaranteed under the constitution. About 50 newspapers under private ownership are published throughout the nation. Most are associated with a political party. The largest dailies are *Ekstrabladet, BT, Berlingske Tidende,* and *Politiken.*

(R.T.A./S.V.A.)

For statistical data on the land and people of Denmark, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

History

The first written evidence of a Danish kingdom dates from the early Viking Age. Roman knowledge of this remote country was fragmentary and unreliable, and the traditional accounts in *Widsith* and *Beowulf* and by later Scandinavian writers, notably Saxo Grammaticus (*c.* 1200), are too mythical and legendary to serve as history. Since World War II, however, archaeological research and the study of place-names have provided considerable information about the earliest settlements.

EARLIEST SETTLEMENTS

The first nomadic hunters, after 12,000 BC, developed a Stone Age culture. About 4000 BC one of the greatest changes in Danish history occurred: the inhabitants adopted the practice of agriculture and stock keeping, and the first farmers began to reclaim land from the forests. From about 3500 BC permanent houses for the dead in large megalithic graves were built, but about 2800 BC a single-grave culture emerged. The change was caused by local factors, including new tools, weapons, and religious rites. In the last phase of the Stone Age, the Dagger period (2400–1800 BC), flint working reached its apogee with the production of technical masterpieces, including daggers and spearheads that were imitations of imported metal weapons.

Bronze and Iron ages

The refined culture of the ruling class in the Bronze Age (1800–500 BC) is indicated by the spiral decorations on the bronzes of the period, in particular the famous Late Bronze Age *lurs* (long, curved metal horns, often found in pairs) from about 1000–800 BC. At about the same time, the wooden plow enabled better exploitation of the cultivated areas.

After 500 BC, bronze was gradually replaced by iron, and a village society developed in a landscape of bogs, meadows, and woods with large clearings. The villages appear to have been moved and the fields abandoned with each new generation. Chiefs and rich farmers lived in houses between 40 and 100 feet in length, the climate now being colder and wetter; as in the Bronze Age, objects of great value were laid as offerings in the bogs. The period up to AD 400 was marked by the large number of villages, and splendidly equipped graves suggest that political power was gathered in fewer hands. More or less fixed trading connections were established with the Romans; about AD 200 the first runic inscription appeared, possibly developed under the influence of the Latin alphabet. The period from 400 to 800 is known as the Germanic Iron Age, but the finds have been few, indicating a time of decline, unrest, and bubonic plague in the 6th century. The first trading markets appeared at Hedeby (near what is now Schleswig, Ger.) and Ribe in the 8th century, and written sources mention the existence of slaves. (M.I.A.L.)

THE VIKING AGE

The northward expansion of the Franks brought Denmark into close contact with European powers. To protect the country from military aggression from the south, a great rampart, the Dannevirke (Danewirk), was built along the border from the Baltic to the North Sea, near the modern town of Schleswig. Dendrochronological dating has shown that the wall was erected shortly after 737, which seems to indicate the formation of a state at that early period. Later, in 808, the Frankish annals describe the building of a wall by King Godfrey (d. 810) and campaigns against other Danish kings. In about 960 the Dannevirke was connected with the wall around Hedeby, the largest city; other centres were Roskilde (on Zealand) and Jelling, probably the seats of the first kings.

Louis I the Pious, the son of Charlemagne, tried to Christianize the Danes. Louis sent a monk, Ansgar, to Hedeby in 826, but his message was resisted; later, however, he was given permission to erect churches in Hedeby and Ribe. The following year he was installed as bishop of Hamburg with the whole of Scandinavia as his see. After Ansgar's death, in 865, his successor, Rimbert, wrote a hagiographic account of his life, *Vita Ansgarii,* which is an important source for 9th-century Scandinavian history.

During the 10th century, after internal struggles between rival kings, the centre of power moved to Jelling, where Gorm became king of Jutland (*c.* 940). On a huge runestone at Jelling, his son, Harald I Bluetooth (Blåtand), attributed to himself the unification of all Denmark, the conquest of Norway, and the Christianization of the Danes. It is possible that he agreed to become a Christian (*c.* 960) in order to avoid German meddling in Denmark, although he was later forced to protect the southern border from a German attack. Probably Harald started the building of the great circular fortresses of Trelleborg (Zealand), Nonnebakken (Funen), and Fyrkat and Aggersborg (Jutland), dated about 980. Under the king's protection the new bishops of Jutland Christianized the kingdom, and the gravesite of Harald's pagan parents at Jelling was made into a Christian shrine. Harald's conquest of Norway was short-lived, and his son Sweyn I Forkbeard and grandson Canute I the Great were each forced to rewin the country. Sweyn exhausted England in annual raids and formed an Anglo-Danish kingdom, a policy that his son and grandson continued until the latter's death in 1042. English missionaries were sent into Denmark to counteract the power of the Hamburg archbishops, but Denmark remained within the orbit of the German prelates. Norway elected a native king in 1035, who also ruled Denmark from 1042 to 1047, when Canute's nephew Sweyn II Estridson was chosen as king. During his reign, in the 1070s, Adam of Bremen composed his *Gesta Hammaburgensis ecclesiae pontificum* (*History of the Archbishops of Hamburg-Bremen*), the first important contemporary source for Danish history.

Unification under Harald Bluetooth

THE 12TH, 13TH, AND 14TH CENTURIES

Working together with the church, Sweyn Estridson strengthened royal power. The country was divided into eight bishoprics: Slesvig, Ribe, Århus, Viborg, Vendsyssel, Odense, Roskilde, and Lund. The royal succession remained in the hands of the local *things.* Five of Sweyn's sons succeeded each other on the throne—Harald Hén (ruled 1074–80), Canute II the Holy (Knud; 1080–86), Oluf Hunger (1086–95), Erik Ejegod (1095–1103), and Niels (1104–34). Their reigns were marked by popular and ecclesiastical opposition to the extent of royal power, as, for instance, during the reign of Canute, whose bailiffs were ruthless in their treatment of the peasants. A rebellion in Vendsyssel forced the king to flee to Odense, where he was killed in St. Alban's Church. Under Erik Ejegod, Scandinavia was recognized in 1103 as an archbishopric with a see at Lund (Skåne), where a great Romanesque cathedral was erected.

In order to defend the southern border, Niels made Erik Ejegod's son Knud Lavard duke of South Jutland. Knud's success against the Wends on the south coast of the Baltic

won him great popularity but also the ill will of the king and his supporters, in particular Niels's son Magnus the Strong, who killed Knud in 1131, causing a civil war. Knud's brother Erik Emune took up the fight against Magnus. In 1134 Erik's army defeated that of Magnus, who was killed along with 5 bishops and 60 priests. Shortly after the battle, Niels visited Slesvig (Schleswig), a centre of Knud Lavard's support, and was killed by the townspeople; his successor was Erik Emune (1134–37). The civil war continued, and by 1146 the kingdom was divided between the sons of Erik Emune, Magnus the Strong, and Knud Lavard. After continued struggles, Knud's son Valdemar was acknowledged as the sole king in 1157.

Kingdom of the Valdemars. The Wends continued their attacks on the Baltic trade and the Danish coast; when the Germans increased their expansion eastward along the Baltic coastline, Valdemar I the Great (1157–82) allied himself with the Saxon prince Henry III the Lion against the Wends and acknowledged the Hohenstaufen emperor Frederick I Barbarossa as his overlord. With the blessing of the church, represented by Absalon, the bishop of Roskilde (later archbishop of Lund), Valdemar undertook repeated crusades against the Wends; in 1169 he captured Rügen, placed the island under his rule, and began to establish Danish hegemony over the Baltic, as described by Saxo Grammaticus. The cooperation of king and church resulted in the crowning of Valdemar's son Canute IV (also called Canute VI) as king in 1170 by the archbishop Eskil; a vigorous state was established and German claims of overlordship were rejected.

The reign of Valdemar

In the early 1180s north Germany was split among petty counts, and Absalon, who ruled during Canute's minority, attacked Pomerania and annexed it along with part of Mecklenburg to the Danish realm (1184). Canute's brother Valdemar, count of South Jutland, defeated the count of Holstein, adding the county to his own territory. When Valdemar II, called Sejr (Victor), became king (1202), the land between the Elbe and the Eider, including Lübeck, was brought under the Danish crown. Valdemar conquered Estonia in 1219, and, according to legend, Dannebrogen, the national flag, came down from heaven during the siege of Revel (Tallinn), which became a strong fortress, marking the culmination of Danish rule over the Baltic. In 1223 Valdemar was taken prisoner by one of his north German vassals but bought his freedom in 1225, promising to give up all the conquered areas except Estonia and Rügen. A final attempt to win back the lost areas led to his decisive defeat in 1227.

Valdemar's son Erik was crowned (1232) during his father's lifetime, and his other sons, Abel and Christopher, were proclaimed dukes; Abel was given South Jutland and Christopher received the islands of Lolland and Falster. As a check against royal misuse of power, a parliament, the *hof*, was established by the high prelates and aristocrats; it met at short intervals and also functioned as the highest court. During Valdemar's reign two essential works appeared: a code of law and King Valdemar's *Jordebog* ("Land Book"; a cadastre, or land register).

Dissolution and consolidation. Soon after Valdemar's death in 1241, a struggle broke out between his sons; Erik was killed in 1250 by the forces of his brother Abel, who succeeded him but soon lost his life during a war on the Frisians in 1252. Christopher was then crowned king, and Abel's eldest son, also called Erik, became duke of South Jutland, which was soon after declared a hereditary duchy. Under Christopher I, the cooperation between church and crown ended. The archbishop, Jakob Erlandsen, demanded the full extension of canon law, but was opposed by both the king and the peasants. Erlandsen was taken prisoner by the king, and Denmark was placed under an interdict. The archbishop was supported by Erik, duke of South Jutland; the count of Holstein, and the prince of Rügen, who attacked Denmark. During the ensuing war Christopher died (1259).

The regents for Christopher's young son, Erik V Glipping, released the archbishop, who left the country. When Erik became king, he was forced by the *hof* to sign a coronation charter (1282), in which he agreed to assemble the *hof* each year, to have no one imprisoned purely on suspicion, and to respect "King Valdemar's Law"; this was the first written constitution. In 1286 Erik was murdered; the election of his son Erik Menved as king (1286–1319) without a charter was a sign that the importance of the *hof* was declining. Erik Menved tried to take advantage of the weakness of the north German states, but he was unable to maintain his early gains because of the country's financial inability to support a mercenary army: at his death in 1319 the state finances were chaotic.

Development of the *hof*

The childless Erik Menved was succeeded by his brother, Christopher II, who was forced to sign a strict charter and was the first king to accept the *hof* as a permanent institution, independent of his personal supporters. He did not abide by the charter, however, and he was driven into exile after a battle with the magnates and the count of Holstein. For a time (1326–30), the young duke of South Jutland, Valdemar, ruled under the regency of the count of Holstein. After Christopher's return, the kingdom was split by a peasant uprising, church discord, and the struggle with the Holsteiners, who received almost all of the country in pawn; Skåne rebelled against its Holstein count and came under Swedish rule.

Holstein rule and reunion. The counts of Holstein ruled Denmark from 1332 to 1340, when one of them was murdered during a visit to Jutland, and Christopher's son, Valdemar IV Atterdag, was chosen king. He married the sister of the duke of South Jutland, who gave the northern quarter of North Jutland as her dowry; he began his reign with the reunion of Denmark as his first priority. By selling Estonia (1346) and collecting extra taxes, he reclaimed some of the pawned areas and brought others back through negotiations or force of arms. In 1360 he conquered Skåne and, a year later, Gotland, and Denmark was reunited. During his reign royal power was strengthened. At a *hof* in 1360, a "great national peace" was agreed between the king and the people. The *hof* was replaced by the Rigsråd—a national council of the archbishop, the bishops, and *lensmænd* (vassals) from the main castles—and the king's Retterting (Court of Law) became the supreme court. Valdemar also attacked major economic problems: after the Black Death (1349–50), he confiscated ownerless estates and regained royal estates that had been lost during the interregnum; the army was reorganized.

Valdemar's war on Gotland and the fall of the wealthy town of Visby brought him into conflict with Sweden and the Hanseatic League, which declared war on Denmark. Sweden's king, Magnus II Eriksson, agreed to the marriage (1363) of his son, crown prince Haakon (Haakon VI of Norway), to Valdemar's daughter Margaret; however, Magnus was soon overthrown by Swedish magnates and replaced by his nephew Albert of Mecklenburg (1364). In 1367 the Hanseatic League, the princes of Mecklenburg and Holstein, and some of the Jutland magnates attacked Valdemar at sea and on land. The king went to Germany to find allies in the rear of his powerful German enemies and succeeded in obtaining a rather favourable peace treaty at Stralsund in 1370, which gave the Hanse trading rights in Denmark and pawned parts of Skåne to the league for 15 years. Valdemar returned home and continued his work of stabilizing the crown's hold on the country. After his death in 1375 the magnates elected Olaf, the five-year-old son of Margaret and Haakon, on condition that he signed a charter. His father died in 1380, and Olaf, under Margaret's regency, also became king of Norway and called himself heir to the Swedish throne.

THE KALMAR UNION (1397–1523)

Rule of Margaret and her heirs. Denmark, Norway, and Sweden were united during the 14th century by dynastic ties. Margaret, who served as regent of both Denmark and Norway during Olaf's minority, worked to win the crown of Sweden for him, but he died in 1387. She was acknowledged as regent in the two countries, and in 1388 rebellious Swedish nobles, dissatisfied with Albert's rule, hailed her as regent in Sweden. The following year her troops defeated Albert's knights and captured the king. The war continued until 1398, when Stockholm was finally turned over to Margaret, who wanted to secure the royal succession; in June 1397 her sister's grandson, Erik

of Pomerania, was crowned king of Denmark, Norway, and Sweden at Kalmar. There negotiations with the Scandinavian magnates were initiated to regulate the mutual relations of the three countries and the power of the new king. There is no record of the discussions, only the coronation charter on parchment and the union document on paper. The latter concerns the conditions for the union, including the election of kings and the internal matters of each country (that is, each would be governed by its own laws). The union document is among the most controversial sources for Scandinavian history: present opinion considers it a draft, signed by only 10 of the 17 magnates mentioned and never accepted by the queen or her successors.

The union document

The primary objective of Queen Margaret, who ruled the union until her death in 1412, was to strengthen royal power. In Denmark she avoided calling the national council, left high posts unoccupied, and reduced the privileges of the nobles. Her economic policy was the most successful aspect of her reign: with the help of extra taxes, she managed to pay back loans, reclaim pawned areas, buy Gotland from the powerful Teutonic Knights, who had occupied the island in 1398, and donate land and gifts to the church. Margaret's foreign policy was based on a desire to keep peace, and she arranged for the marriage of her successor, Erik, to Princess Philippa, daughter of Henry IV of England.

Erik attacked the Hansa in 1410, and after his enthronement in 1412 he promoted national trade in Denmark and privileges for English merchants; he also gave Danish towns a monopoly on commerce and crafts (1422) and began to collect custom duties in the Sound in 1429 to replace the lost revenues from the Skåne market. His foreign policy was not successful: the conflict with the Hansa was intensified, and he also made enemies of the Teutonic Knights. The king increased the number of Danes appointed to offices in Sweden and Norway, arousing the anger of the native aristocracies, and his efforts to control church appointments irritated the clergy. Constant warfare made heavy demands on the exchequer and forced him to increase taxation and debase the coinage, which worsened the economic situation. In 1413 he had the Danish *hof* recall the fiefs of the Holsteiners, which started a long war, and in 1426 Lübeck and its allies opened hostilities over trade privileges and blockaded the Scandinavian countries, which especially affected the mining districts of Sweden. In 1434 a rebellion broke out in Bergslagen (central Sweden) under Engelbrekt Engelbrektsson, who was elected guardian of the realm. He and the Swedish council renounced their allegiance to Erik. The spirit of revolt spread to Erik's enemies in Denmark and Norway, and in 1438 he went into exile in Gotland. He was deposed in all three kingdoms during the years 1438–42.

Erik's nephew, Christopher of Bavaria, was called by the Danish council to become king in 1440 and was later accepted as king in both Sweden and Norway. He promised to administer the three countries separately and to use only native *lensmænd*. When Christopher died without heirs in 1448, the union was temporarily dissolved and the Danish council elected Count Christian of Oldenburg king as Christian I; in the following year he was also proclaimed king of Norway. (H.En./M.I.A.L.)

Until 1520 the union was marked by wars between Denmark and Sweden, interrupted by periods of peace. The Danish kings and most of their nobles sought to follow a policy of supremacy, which was opposed by the Swedish kings and guardians of the realm. Throughout the period the struggle for power between the king and the magnates continued, although some Swedish nobles supported the kings of Denmark.

The estates. During this period the people became more sharply divided into estates. Agriculture was then, as at all times, the principal industry; the cultivated land, apart from about 1,000 manors, consisted of about 80,000 farms, clustered together in groups of 5 to 20 as villages. These were managed by peasant farmers in common, whether they owned their farms themselves or were tenants paying a yearly rent (*landgilde*). In 1500 about 12,000 peasants owned farms, about 18,000 were leasehold tenants of crown lands, and about 30,000 were leasehold tenants of lands belonging to the church or the nobles.

Peasants, church, and nobility

With its seven bishoprics and more than 70 monasteries, the church was immensely rich. It derived a huge income from its lands and farms and drew still greater revenues from the tithes on the entire grain production of the country, one-third going to the bishops, one-third to the parish churches, and one-third to the parish priests. Since the Council of Basel, the pope had assumed the right to make all ecclesiastical appointments, although he allowed certain nominations by the king. The nobles, however, tried to reserve some of these for their younger sons, who were too poor to buy manors.

The 15th century marks a turning point in the history of the Danish nobility. Until then any Dane could become a noble by presenting himself well-equipped for military service at his own expense. In return he was exempted from all taxes; but from the 15th century he had to show that his forefathers had enjoyed tax exemptions for at least three generations. The king sought to assume the right to issue titles of nobility, but despite this the nobility in this period developed the characteristics of a caste. During the 15th century the nobility comprised 264 families, but this number fell to 230 in 1500 and to 140 (including at most 3,000 persons) in 1650; the Gyldenstjerne and the Rosenkrantz (whose names are commemorated in Shakespeare's *Hamlet*) were among the most important.

The nobility acquired lands in great numbers and were capable agriculturists, responsible for increased exports of farm produce. The country had a long-standing market for its horses; now stall-fed bullocks were added. Landowners, lay and clerical, also became merchants, many of them having their own ships. (A.E.Cn./M.I.A.L.)

The first Oldenburgs. The first three kings of this still (through the collateral branch of Glücksborg) reigning house—Christian I (1448–81), John (Hans; 1481–1513), and Christian II (1513–23)—tried to foster the economies of the towns while curbing the direct trade of German Hanseatic merchants with the peasants.

With Christian I began the revival of the coronation charter, which now included a guarantee for the national council's participation in foreign policy, legislation, taxation, and justice. If the king failed to respect the guarantees, his subjects had the right to renounce him, but this did not prevent the early Oldenburgs from ignoring the charters. Christian attempted to circumvent the council by calling a meeting of the estates (1468), a practice followed by his successors. After the death of the last male heir to the Holstein counts, Christian reached an agreement with the family whereby he became count of Slesvig (South Jutland) and duke of Holstein (1460), with the two areas to be "eternally undivided" and ruled by a royal heir chosen by the local nobility. In paying off a number of princes who had claims on the territories, Christian ran heavily into debt, which, together with the costs of the war with Sweden, forced him to pawn the Norwegian Shetland and Orkney islands to the Scottish king in order to provide a dowry for his daughter.

Christian I and the coronation charter

One of the major concerns of the first Oldenburgs was to reestablish the Kalmar Union. Danish opinion held that the country's power depended on the union, and many Swedish nobles desired a union so long as their influence on home affairs could be maintained. In 1464, however, a rebellion broke out that Christian's troops failed to suppress, and his attempt in 1471 to force the Swedes back into the union was unsuccessful.

Christian died in 1481 and was succeeded by his son John (also king of Norway from 1483), who wanted to reduce the power of the nobility and the Hansa and to create a strong Nordic monarchy with support from the peasants and burghers. Many administrative posts were given to nonnobles, and the king signed trade agreements with the Dutch and English. He was also acknowledged as Swedish king in 1483, but he was not crowned until 1497, after a war between the two countries. He ruled in Sweden until 1501, when rebellious Swedish nobles recalled Sten Sture the Elder, who had served as guardian of the realm from 1470 to 1497. Another war between Denmark and Sweden lasted from 1506 to 1513, and from 1510 to 1512

John was also involved in a successful war with Lübeck.

Christian II succeeded his father in 1513. A struggle broke out in Sweden between the Sture party (led by Sten Sture the Younger) and the union party (led by Archbishop Gustav Trolle); in 1520, after Trolle had been captured by the Stures, a Danish army attacked Sweden and defeated the Sture army. In November 1520 Christian II was crowned hereditary king of Sweden, and 82 members of Sture's party were executed in the "Stockholm Bloodbath." Christian returned to Denmark, leaving the Swedish government in the hands of the archbishop and his allies, who soon faced a rebellion led by Gustav Vasa. After a period of warfare Vasa was elected regent of Sweden (1521). In Denmark Christian attempted to increase his power by ignoring the nobles and replacing them with men from the burgher class; he also interfered with the affairs of the church. The opposition to the king grew, and in 1523 the members of the council from Jutland renounced allegiance to him and joined his enemies. Lübeck and Christian's uncle, Frederick of Holstein-Gottorp, joined the rebellion, and he was crowned king of Denmark and Norway as Frederick I in 1523, when Christian II fled from the country. Sweden elected Gustav I Vasa, and the Kalmar Union was permanently dissolved.

The "Stockholm Bloodbath"

The council and the people. The peasantry suffered a decline under the Kalmar Union. The towns enticed young people from the farms, which, together with a reduction of the labour force due to the Black Death, caused an increase in abandoned farms. This led to semi-serfdom, *vornedskab,* practiced especially in Zealand. By the 16th century, those tenured peasants who lived near the manor worked off a portion of their taxes by service at the manor.

Under the Kalmar Union, Danish towns prospered and the influence of the burghers grew. By 1500 there were approximately 80 towns, most of them fortified but all small; Copenhagen had at most 10,000 inhabitants. The monopoly on internal trade granted by Erik of Pomerania improved the economic position of the burghers, and many German merchants took out citizenship in the towns in order to compete.

Disappearance of the *hof*

During the Kalmar Union, the old *hof* disappeared and the participation of the provincial *things* in legislation and royal elections ceased, while the people were represented by the estates, which remained unimportant throughout the period. The national council, composed of the bishops and nobles chosen by the king, including the highest civil servants (the *hofmester,* or master of the court, in charge of finances; the *drost,* the chief political and judicial officer; the *kansler,* or chancellor; the *marsk,* or marshall, in charge of military forces; and the *rigsadmiral,* or admiral), held the power of legislation and taxation together with the king. The council's consent was necessary for declarations of war, and, together with the king, it served as the highest court, but the entire council was seldom called, and it had little influence on daily administration. The fiefs were controlled by the king's representatives, who collected taxes and upheld the law; these positions were never made hereditary.

The major political conflict during the Kalmar Union was between the monarchs and the nobility. The high nobility never accepted Christian II's strong monarchy, and its members were his most bitter enemies. Frederick I (1523–33) adopted a cautious policy toward both the nobility and the peasants, and he tried to reconcile the Danish, Dutch, and Hanseatic merchants; thus, when Christian II tried to regain his power by invading Norway in 1531–32, there was no national rising, and Christian was taken prisoner. On accession to the throne, Frederick had promised the bishops to fight heresy. Actually, he invited Lutheran preachers to the country, most probably to expand the royal power at the expense of the church.

Civil war and the Lutheran Reformation. After the death of Frederick I in 1533 the Catholic and conservative majority of the Rigsråd once more triumphed. They postponed the election of a new king, fearing that the obvious candidate, Prince Christian (later King Christian III), if elected, would immediately introduce Lutheranism. They tried unsuccessfully to sponsor his younger brother Hans. Civil war, however, broke out in 1534, when the burgomasters of Malmö and Copenhagen accepted help from the Lübeckers, who, under the pretext of restoring Christian II, hoped to regain their mercantile supremacy and control of the Sound. The landing of Lübeck troops in Zealand in the early summer of 1534 roused the Jutland nobility. Now even the Roman Catholic bishops supported Prince Christian. Count Christopher of Oldenburg was leader of the forces of Lübeck, while Christian's general was the Holstein noble Johan Rantzau, a Lutheran. Rantzau subdued a revolt of the Jutland peasants and the civil war ended in the summer of 1536. The Catholic bishops were taken into custody and their property confiscated; the monasteries were dissolved and vast estates came to the crown.

In October 1536 the estates sanctioned a Danish Lutheran Church and in 1537 appointed new bishops, all of burgher descent. They had, however, no political influence, as bishops no longer sat in the Rigsråd. The church organization was finally established in 1539. The purged national council that emerged after the Reformation was soon able to assert itself. The charter issued by Christian III differed only slightly from earlier ones with regard to the privileges of the nobility and the constitutional power of the Rigsråd. The king's attempt to make the throne hereditary did not quite succeed. The Rigsråd named Prince Frederick as the successor of his father and the king's charter provided that a Danish prince should always be elected, but this was omitted in Frederick II's charter in 1559. The national council thus suffered no permanent loss of elective power.

(As.F./M.I.A.L.)

The strengthened monarchy

The monarchy was decisively strengthened by the civil war, primarily by the confiscation of church property. The nobility no longer had much to gain as an independent political body, and they chose to take part in the politics of the strengthened monarchy. A noble could be a member of the Rigsråd, govern a county on behalf of the king and the council, or simply cultivate his domain to profit from the rising prices on grain and cattle. The merchants of Copenhagen and Malmö had fought Christian III, but they favoured a strong monarchy that would protect their interests in the Baltic trade. The monarchy built a strong public administration in Copenhagen (Chancery, Rent Chamber) and even in far-off Norway. The foundations of absolutism were laid during Christian's peaceful reign.

The strain on the public finances during the reign (1559–88) of Frederick II, resulting from the war with Sweden, was relieved through heavier taxation on the farmers. But the main income came from a duty in the Sound on the constantly increasing trade in the Baltic. Originally a fixed duty per ship, it was changed into a fee on tonnage; it was at the king's own disposal, out of reach of the council. The Sound was considered Danish national waters; this fiction and the Sound duty remained until 1857.

THE 17TH AND 18TH CENTURIES

Christian IV (1588–1648), who succeeded his father at the age of 10, thus had favourable political and economic conditions for his ambitious policies. For seven years, an aristocratic regency headed by the aging chancellor, Niels Kaas, was able to influence the future ruler. The first half of Christian's personal reign was in every respect a success, marked by the dynamic king's many initiatives: establishing trading companies, acquiring overseas possessions, investing in a colony in India at Tranquebar, founding new towns, and erecting monumental buildings in the capital and elsewhere. The strongest incentive in his foreign policy was to secure Danish control of the Baltic, into which Sweden was expanding. Christian reacted by intervening in the Thirty Years' War to strengthen the position of Protestantism and to secure a broad sphere of interest in Germany as a counterweight to Swedish expansion, but he was defeated in 1626. From this reversal dates the gradual decline of Denmark-Norway's role in European politics. Nevertheless, the king's national government, public administration, jurisdiction, and promotion of business and new industries had great importance for the future.

Christian IV is regarded as one of the greatest Danish rulers, a central figure in later drama, poetry, and art. But in reality the military catastrophes weakened the position

of the monarchy, so that the high nobility decided to curtail the power of his successor, Frederick III (1648–70).

Introduction of absolutism. Absolutism was nevertheless introduced during Frederick's reign, when the magnates proved unable to handle a central government. After the military debacles in 1658–60 (when Sweden's Charles X Gustav attacked Jutland from the south and marched to Zealand over the frozen sounds of Funen—the Belts—in the winter of 1658; Denmark lost Skåne, Halland, and Blekinge, and Norway lost Bohuslän), the nobles even refused to pay any taxes. The situation in 1660 was exploited by the king's councillors, who drafted a new constitution that eliminated special political privileges of the nobility and proclaimed the king absolute sovereign. This constitution (and a secret "King's Law" of 1665, which is said to be the most absolutist of all European theories of absolutism) lasted until 1848 with only minor modifications.

Denmark's governing bureaucracy

After 1660 Denmark was governed by an efficient bureaucracy, but the political leaders came from the class of great privileged landowners; wealth, not noble birth, gave access to this class. The government in Copenhagen consisted of "colleges." There were five as a rule—namely, the old Chancery, the Rent Chamber, and new colleges for commerce, war, and the navy. Top decisions were made by a secret council, in which leaders of the colleges could easily influence the king. Local administration remained largely unchanged after 1660, but the government took pains to curtail the military power of the new county governors (*amtmænd*). The absolutist kings, very unlike their Swedish colleagues, were rather anonymous, in part because of their feeble mental powers.

After 1660 the crown reduced its properties, which had been greatly increased by the Reformation, through sales to its bourgeois creditors (who thus moved into the class of great landowners). The state compensated for loss of income by increasing taxes on the land according to the value of the holding of each peasant. The new assessments made in the period from 1660 to the 1680s served as the bases of taxation in both Denmark and Norway until the 19th century. Until 1660 the king and the council had acted as supreme court; in 1661 the Danish supreme court was created, and appeals could be made to it from the whole kingdom. Law was codified in Denmark in 1683.

Foreign policy. Denmark's participation (1709–20) in the Great Northern War demonstrated that even with alliances it had no hope for recapturing the territories it had lost to Sweden during the preceding century. On the other hand, Sweden no longer had the strength to invade Denmark from the south in alliance with the house of Gottorp (Slesvig). The king decided on a careful foreign policy to keep a balance in the north and to safeguard communications between Denmark and Norway. This necessitated alliances with Russia and the Netherlands and, from time to time, France. This policy succeeded for the rest of the 18th century, probably because of the common European need for free access to the Baltic. In the 1770s the Gottorp lands in Schleswig and Holstein were brought under Danish rule.

The importance of freedom of the seas

During the 18th century Denmark-Norway acquired an important merchant marine and a navy. Freedom of the seas had become a vital issue and a difficult problem, complicated especially by the export of Norwegian timber to England. During wars in the middle of the century (1740–63) Denmark-Norway had to bow to the British claim of ruling the waves. But during the U.S. War of Independence (1775–83) the Danish foreign minister Andreas Peter Bernstorff in 1780 organized an armed neutrality treaty with Holland and Sweden, whose King Gustav III had married a Danish princess. Because of the war between England and France, Denmark and Sweden prolonged the treaty in 1794, which Russia and Prussia renewed in 1800. Norwegian export interests would have been threatened, however, if England considered these treaties hostile acts, so in 1780 Bernstorff also concluded a special treaty with England, much to the annoyance of Russia. Such a policy of balance proved to be impossible after 1800. (G.Sa./M.I.A.L.)

Trade. Denmark, poor in natural resources except for its soil, made no important economic gains in the 18th century. No important industry developed. Following mercantilist theory the government supported trade, to the benefit of Copenhagen merchants. But Denmark lacked the political strength to exploit the strategic position of Copenhagen; imports dominated its trade. Except for oxen and meat, Denmark had very little to export. Eastern Norway was made an outlet for Danish grain in the 1730s, but the grain was inferior and normally could not compete with Baltic grain on the western European markets.

The principal reason for Denmark's stagnant economy was the backward state of Danish agriculture in the 18th century. A body of some 300 Danish landlords owned about 90 percent of the Danish soil, grouped in 800–900 estates. The landlords were the real rulers of the country, because their social position gave them privileged positions in filling the leading posts in the administration, the chanceries, and the Rent Chamber.

A price depression beginning in the 1720s enabled the landlords to use their position to impose very strict laws and regulations on the Danish peasants, who lived in villages, renting their farms from landlords whose demesne lands alone covered about 10 percent of the land. To get cheap labour, a compulsory provision that one live in the village of his birth was required for all people between 4 and 40 years of age. As the system was coupled with military conscription, the landlord could threaten a young peasant with at least six years of army service if he did not rent a farm. Every tenant had to perform labour on the landlord's domain for an average of three days a week. This work was considered to be the rent of the peasant's holding. A tenant had no right to demand a contract when he took over a holding, nor could he demand payment for improvements he might make on the holding when the lease expired or was lifted by the landlord. Each landlord also had the right of petty jurisdiction on his estate. Even if the landlords got cheap labour and the army received sufficient manpower by this system, Danish agriculture suffered from incredibly low productivity. The farmers performed poorly on the domains of the landlords; they had too little time to cultivate their own holdings; and they had no reason whatsoever to improve them.

Compulsory service

Until the 1780s, Danish society seemed stagnant. A financial crisis in the 1760s, after Russian threats during the Seven Years' War, was solved by a lasting poll tax. In 1770 a German doctor, Johann Friedrich Struensee, depending on palace intrigues and the queen's bed, gained control of the government through the half-mad king Christian VII (1766–1808). For a year and a half, freedom of the press and intense reform activity reigned, but mostly on paper. Struensee had no popular support, and he naturally provoked resistance and fury among the landlord class. He was arrested for crime against the majesty and, in April 1772, was sentenced to death. His short reign has been classified as another failure of the enlightened despotism of the 18th century. The old men who came back to power led an even more reactionary policy than before, one lasting until a bloodless coup d'état in 1784.

The years between 1784 and 1797 have been called the happiest period in all Danish history. Danish politics of those years were led by Bernstorff, Ditlev Reventlow, and Ernst Schimmelmann, all from the landlord class, by the benevolent crown prince Frederick (Frederick VI, 1808–39), and by the Norwegian jurist Christian Colbjørnsen. Notable reforms included liberal custom tariffs (1797) and the abolition of the Danish grain monopoly in Norway. But above all, the time was an age of land reforms, beginning in 1786 and lasting until the state suffered financial bankruptcy in 1813. Sixty percent of the Danish peasants became landowners. Compulsory residence, compulsory labour on the domains of landlords, and private jurisdiction were abolished, and the land was redistributed and made into independent farms. The army had to get soldiers by ordinary conscription. Landlords were compensated for the rights they lost, and together with the new landowning farmers they were assured stable labour by strict legislation on the landless crofters. The land reforms were possible because of a continuous rise in grain prices between 1750 and 1815 and because the new men of 1784 had carried out successful reforms on their own estates. As responsible

Agricultural reforms

politicians they had an insight into the benefits of a mild inflation and a liberal allocation of state credit, with which they guided the transition to peasant landownership. No doubt the revolution in France, beginning in 1789, influenced this evolution. The example of the independent French farmers after 1789 hindered an evolution like that in England, with great domains and a numerous class of rural workers. From the land reforms, and from the school act of 1814, which introduced compulsory schooling for all children between ages 7 and 14, there stemmed a high standard of Danish agriculture. The Danish land reforms are remarkable also as the only successful feat of European enlightened despotism.

THE NAPOLEONIC WARS AND THE 19TH CENTURY

The Napoleonic Wars of the early 19th century tore Denmark-Norway out of a peaceful period that had lasted since 1720. The armed neutrality treaty of 1794 between Denmark and Sweden, to which Russia and Prussia adhered in 1800, was considered a hostile act by England. In 1801 a detachment of the English navy entered The Sound and destroyed much of the Danish fleet in a battle in the harbour of Copenhagen. When the English fleet next proceeded to threaten the Swedish naval port of Karlskrona, Russia started negotiations with England. The result was a compromise, which Sweden was forced to adopt in 1802. The neutrality treaty had fallen in ruins. Denmark-Norway, nevertheless, managed to keep out of the wars and to profit from them until 1807.

The Treaty of Tilsit (1807) between France and Russia worsened the situation. In 1805 France had lost its fleet to the English at the Battle of Trafalgar. England feared that the continental powers might force Denmark to join them so that the Danish navy could be used to invade England. To eliminate this threat, England resorted not to diplomacy but to force. In September English troops occupied Zealand and an English fleet bombarded Copenhagen. Denmark had no choice but to capitulate to the English demands. On October 20 the English commander sailed away with the whole Danish fleet. The "fleet robbery" was severely criticized, even in the British House of Commons. Because of fear of a French or Russian occupation, Denmark chose what seemed to be the lesser evil and joined the continental alliance against England on October 31. This step also meant war with Sweden. Denmark might have reacted differently if England had used diplomacy, but the events of September had been too much of an affront to the Danish government and especially to the crown prince Frederick. An alliance with England was no longer possible.

The loss of Norway. The continental blockade of England, which was against Danish interests, was a catastrophe to Norway. Fish and timber exports were stopped, as well as grain imports from Denmark. The consequences were isolation, economic crisis, and hunger. In 1810–13 England consented to some relaxation of its counterblockade against Norway. As a whole, however, the years 1807–14 convinced leading groups in Norway that they needed a political representation of their own.

Sweden's attack from the south

Denmark-Norway remained an ally of Napoleon until 1814. After Napoleon's defeat at the Battle of Leipzig (1813), Sweden repeated its 17th-century strategy by attacking Denmark from the south. By the Treaty of Kiel (Jan. 14, 1814), Denmark gave up all its rights to Norway (but not to the old Norwegian dependencies of Iceland, the Faroes, and Greenland) to Sweden.

The Danes did not intend this agreement to end their union with Norway. While remaining outwardly loyal to the Treaty of Kiel, the Danish government worked for the eventual return of Norway. This probably is why the crown prince Christian Frederick, governor of Norway, in collusion with the Danish king, organized an uprising against the Treaty of Kiel. A constituent assembly was called by Christian Frederick to meet at Eidsvoll, 40 miles north of Christiania (modern Oslo, Nor.). It drew up a constitution (which still exists) on May 17, 1814, and elected Christian Frederick to the throne of Norway.

Norwegian independence got no support from the great powers, and Sweden attacked Norway in July 1814. After a fake war of 14 days, Christian Frederick resigned, and Danish hopes of reunion were lost. (G.Sa.)

Economic development and the liberal reform movement. *Economic consequences of the war.* The Napoleonic Wars had proved a national catastrophe for Denmark, both economically and politically. The policy of armed neutrality had failed, and that part of the fleet not destroyed had been surrendered. Copenhagen, the capital and the country's commercial and administrative centre, had been devastated by the bombardment of 1807, and Norway had been lost at the Treaty of Kiel in 1814. Trade had been seriously affected by the blockade of England, and the widespread overseas connections that formerly had played so large a part in the economic life of Denmark could not be resumed.

Copenhagen's role as an international financial and trading centre was taken over by Hamburg, whence even a considerable part of Danish home trade was controlled. Inflation further contributed to the crisis. The state was forced to make a formal declaration of bankruptcy, and not until 1818, when an independent national bank with sole rights to issue banknotes was established, was economic stability possible. It was 20 years, however, before the coinage rose to parity with the silver standard, and banknotes were first redeemable only in 1845.

The already considerable economic crisis was worsened by low grain prices. The loss of Norway and the high import duties on grain that Great Britain imposed at this time deprived Denmark of its surest markets for grain export. The agricultural crisis resulted in the compulsory auctioning of many estates and farms, forcing the agrarian reform to a complete standstill.

From 1830 economic life took a turn for the better with, among other things, more stable prices for agricultural products, increased trade, and the first signs of industrialization.

The liberal movement. Denmark's government under Frederick VI (1808–39) could be described as a patriarchal autocracy. In the Privy Council, which was regularly convened after 1814, Poul Christian Stemann became the leading figure and was responsible for the government's strongly conservative policies until 1848. His close colleague, Anders Sandøe Ørsted, pleaded for a somewhat more liberal policy, at least on economic questions. After the July Revolution in France, a demand was made in Denmark for a liberal constitution. The government was forced to make concessions, and in 1834 four provincial consultative diets (or assemblies) were created, two in the kingdom itself, one in Schleswig (Slesvig), and one in Holstein. These were not representative bodies, being composed of wealthy landholders, and their function was only advisory. As the liberal movement grew in strength, especially in the academic world and among the middle classes, the liberal press, whose leading journal was *Fædrelandet* ("The Fatherland," established in 1834), subjected the monarchy and its conservative administration to severe criticism. When the popular Frederick VI died in 1839, the liberals had great hopes of his successor Christian VIII, who, during his youth as regent in Norway, had appeared as the spokesman for a liberal government. Over the years, however, he had become much more conservative and as king of Denmark did not consider the time ripe to curb the absolute monarchy. He confined himself, therefore, to modernizing the administration, especially, between 1837 and 1841, through a program of establishing local government and granting some independence to parishes and counties.

Creation of provincial diets

Parallel with the liberal movement ran the farmers' movement. This started as a religious movement but soon became dominated by social and political ideas, with agitators such as Jens Andersen Hansen leading the way. When the government intervened, the liberals and farmers joined forces against the common adversary. In 1846 the farmers' case received support when a group of liberal reformers led by Anton Frederik Tscherning founded the Society of the Friends of the Peasant (Bondevennernes Selskab), which developed into the Liberal Party (Venstre).

The 1849 constitution. After the death of Christian VIII in January 1848 and under the influence of the February

revolution in Paris and the March revolution in Germany, the new king, Frederick VII (1848–63), installed the March Cabinet, in which the National Liberal leaders Orla Lehmann and Ditlev Gothard Monrad were given seats. After a constituent assembly had been summoned, the absolute monarchy was abolished and was replaced by the constitution of June 5, 1849. Together with the king and his ministers there was now also a Parliament with two chambers, the Folketing and the Landsting, both elected by popular vote but with a property-owning qualification as a prerequisite for a seat in the Landsting. Parliament, together with the king and government, shared legislative power while the courts independently exercised judicial power. The constitution also secured the freedom of the press, religious freedom, and the right to hold meetings and form associations.

The National Liberals and the Schleswig-Holstein question. Nationalism was, together with liberalism, the most important movement in the 19th century. In Denmark, national feelings were inflamed by the conflict with Germany on the Schleswig-Holstein question. After the loss of Norway, the Danish monarchy consisted of three main parts: the kingdom of Denmark and the duchies of Schleswig and Holstein, the last of which was a member of the German Confederation. Whereas Holstein was German, Schleswig was linguistically and culturally divided between a Danish and a German population. When the liberal German-speaking population in Schleswig opposed autocratic rule and demanded a free constitution and affiliation to Holstein and the German Confederation, a Danish National Liberal movement emerged and demanded that Schleswig be incorporated in Denmark (the Eider Policy, named for the Eider River, which formed the southern boundary of Schleswig). When the National Liberal government officially adopted this policy in 1848, the Schleswig-Holsteiners resorted to arms. The rebellion received military aid from Prussia, and the Danish army could not suppress it. The war, which lasted three years, ended in the agreements of 1851 and 1852 in which Denmark pledged to take no measures to tie Schleswig any closer to itself than to Holstein. The Eider Policy was thus abandoned, and the June constitution of 1849 applied only to Denmark.

The Eider Policy

The National Liberal government was succeeded in 1852 by a Conservative (Højre) government under Christian Albrecht Bluhme. Under the influence of the Pan-Scandinavian movement and the German Confederation's constant interference in constitutional matters in Schleswig and Holstein, the Eider Policy again won ground, and the Conservative government was replaced in 1857 by a moderate National Liberal government led by Carl Christian Hall. In 1863, in the belief that Prussia was preoccupied with the Polish rebellion against Russia and in expectation of support from Sweden, the government separated Holstein from the rest of the state and conferred a joint constitution on the kingdom and Schleswig. This "November constitution" meant that Schleswig was annexed to Denmark, in contravention of the agreements of 1851 and 1852.

Prussia, however, under the leadership of Otto von Bismarck, reacted immediately, and in February 1864 war broke out between Denmark on the one side and Prussia and Austria on the other. After the Danish defeat at Dybbøl and the consequent occupation of the whole of Jutland, Denmark was forced by the Treaty of Vienna to surrender all of Schleswig and Holstein to Prussia and Austria.

The conservative regime. *Realignment of political factions.* The defeat in 1864 led to the fall of the National Liberal government. Under Christian IX (1863–1906) a Conservative government was appointed, and in 1866 a new constitution followed that introduced electoral rules giving the Landsting a distinct conservative leaning, with great landowners and civil servants as the dominating elements. The National Liberal Party was swallowed up by the Conservative Party. As a counterweight, the various groups that represented the farmers combined together in 1870 to form the United Left (Forenede Venstre), which in 1872 secured a majority in the Folketing. The Left demanded that the 1849 June constitution be reintroduced together with a number of other reforms. With Jacob Brønnum Scavenius Estrup, a great landowner, as prime minister (1875–94), however, a strictly conservative policy was pursued. Despite the opposing parliamentary majority, the government forced its policy through by means of provisory law and with support from the king. The result was that all reforms came to a standstill. Not until the "compromise" of 1894 was the crisis solved, at which time Estrup himself left the government. The demand for parliamentary democracy was not granted, however, until the 1901 election, when the Left Reform Party (Venstre-reformparti), an offshoot of the Left, came to power, and what has become known in Denmark as the "Change of System" was introduced.

The United Left

Social and economic change. The progress of the Left and the formation of the Social Democratic Party in the 1870s must be viewed against the background of the great economic and social changes. During the 1850s and 1860s a network of railroads was created, industrialization began, agrarian reforms were introduced, and a number of technical improvements in grain production were effected. In the years between 1870 and 1901 the urban population increased from 25 percent to 44 percent of the total population. The rapid development of harbours, ships, and foreign trade meant that the shortage of raw materials, such as iron and coal, did not hinder the development of industry to any essential degree. There was a steady stream of foreign capital to Denmark. Trade unions and employers' federations were established at this time and spread nationwide by 1899. The fall in the world market price of grain after 1875 resulted in an increased production of butter and bacon. Britain became even more the main market for agricultural products. Even the smallest farm arranged its production with exports in mind, while at the same time certain foodstuffs were imported. Standardization of butter and bacon and their export was arranged by the farmers on a cooperative basis and with a view to the existing struggle with townspeople and the great landowners. The cooperative movement won ground in rural areas. Culturally, the farmers gathered around the folk high schools, educational institutions with a mainly liberal arts

program, inspired by the ideas of N.F.S. Grundtvig, the writer, educationist, and theologian.

THE 20TH CENTURY

The Left Reform government that came to power under the "Change of System" in 1901 went swiftly to work on a number of reforms. Parliamentary supremacy, requiring the king to appoint a government having the support of Parliament, began in that year. A free-trade law that corresponded to the agricultural export interests was passed; in conformity with the ideas of Grundtvig, the state church was transformed into a folk church with parochial church councils; the educational system was democratized; and changes in the system of taxation were effected so that income and not land was the main criterion for taxation. After the victory over the Conservatives, it became apparent that it was impossible for the Left Reformers, led by Jens Christian Christensen, to remain united. In 1905, therefore, the radical faction broke away to become the Radical Liberal Party (Radikale Venstre), the most important members of which were Peter Munch and Ove Rode. Between 1913 and 1920 the Radicals, supported by the Social Democrats, were in power. In 1915 the constitution was revised, and the privileged franchise to the Landsting was revoked, although the electoral qualifying age of 35 was retained. At the same time, the franchise to both the Folketing and the Landsting was extended to women, servants, and farm hands. The right-wing majority in the Landsting agreed to the constitutional reform on condition that the single-member constituency be replaced by proportional representation. There followed a number of reforms, including a judicial reform introducing trial by jury and a land reform bill that aimed to redistribute land from the large estates to increase the size of smallholders' farms.

Formation of the Radical Party

Foreign policy and World War I. After the Franco-German War (1870–71), Danish foreign policy was developed along neutral lines. There were strong differences of opinion between the Conservatives and the Left on the way in which this should be carried out. The Conservatives demanded a strong defense policy, and J.B.S. Estrup carried through the fortification of Copenhagen. Within the Left itself there was disagreement on the lines the neutrality should take. The most radical viewpoint was held by Viggo Hørup, who wanted complete disarmament. After the split within the Left in 1905, the Radical Liberal Party continued Hørup's ideas. In the years before 1914, it became increasingly important to define Germany's intended attitude to Denmark in the event of a European conflict. The Germans were well aware that the Schleswig affair had left a good many Danes with a loathing for everything German, while the constant friction between the Danish minority and the German administration in Schleswig added fuel to the flames. Danish governments after 1901 made persistent efforts to assure Germany of Denmark's benevolent neutrality, but the disagreement over this policy's implementation remained unreconciled. At the outbreak of war, Germany forced Denmark to lay mines in the Great Belt in August 1914, and, as the British fleet made no serious attempts to break through, neutrality was maintained.

World War I gave Denmark, together with a number of other neutral countries, an extremely good export market to the belligerent countries but an inevitable shortage of supplies. With a widespread overseas trade, the country's economic life was exceedingly vulnerable and became especially so after Germany opted for unrestricted submarine warfare beginning in 1917. Denmark's exports to Great Britain were, to a certain extent, reoriented to Germany. There was a shortage of raw materials in both agriculture and industry, and the government rationed a number of consumer goods and controlled the country's economic life to a certain extent.

The interwar period. By the Treaty of Versailles it was decided that part of Schleswig should revert to Denmark in accordance with the principle of self-determination. The boundary was determined by a plebiscite in 1920. The discontent that arose as a consequence of the drawing of the boundary, coupled with labour unrest and dissatisfaction with remaining wartime restrictions, led to the fall of the government in the same year. It was succeeded by a Left government supported by the Conservatives. From 1924 to 1926 the Social Democrats (Socialdemokratiet), under the leadership of Thorvald Stauning and supported by the Radicals, were in power. The years 1926 to 1929 saw the Left in power again, supported by the Conservatives.

The recurring problem for the governments of the 1920s was the critical economic conditions that followed World War I. In 1922 the country's largest private bank, Landmandsbanken, failed. At times unemployment reached a high level. The Social Democrats scored a great victory at the polls in 1929, and a coalition government was formed with the Radical Party under the leadership of the Social Democrat Stauning, with Peter Munch as foreign minister.

Monetary problems

Economic crisis. The Great Depression of the early 1930s led to unemployment, which in 1933 affected 40 percent of the organized industrial workers. When Great Britain went off the gold standard in 1931, Denmark followed suit. The greatest blow to the Danish economy, however, was the system of preferential Commonwealth tariffs established in 1932. To cope with the crisis, the government subjected foreign trade to stringent control by the establishment of a "currency centre" and won the support of the Left in the "Kanslergade compromise," by which it was agreed to devalue the krone and to freeze existing wage agreements by law. In addition, the Left supported social reforms that included old-age pensions and health, unemployment, and accident insurance. A number of measures were also adopted in support of agriculture. The general election of 1935 returned the Social Democrats again, and after the elections to the Landsting in 1936 the government coalition of Social Democrats and Radicals held the majority in both the Folketing and the Landsting. Trade improved, and during the late 1930s industry again began to expand.

Foreign policy. Denmark joined the League of Nations in 1920 and worked for a peaceful solution to international problems during the interwar period. When Adolf Hitler came to power and Germany began to rearm, Denmark's position was again vulnerable. Although Germany had never recognized the alteration in its boundary as laid down by the Treaty of Versailles, Hitler did not raise the matter. Under Foreign Minister Munch's leadership, Denmark tried in vain during the 1930s to obtain recognition of the boundary, and at the same time it avoided all measures that might possibly offend its powerful neighbour. When in 1939 Hitler offered nonaggression pacts to those countries that might feel threatened by Germany's expansionist policy, Denmark, in contrast to the other Scandinavian countries, accepted the offer.

Denmark during World War II. On the outbreak of war in 1939 Denmark, in common with the other Nordic countries, issued a declaration of neutrality. On April 9, 1940, German troops crossed the border, and after token resistance the Danish government submitted to a military occupation of the country. Formally, however, Denmark remained a sovereign state until Aug. 29, 1943, and in this its position differed from the other occupied countries of Europe. A coalition government was formed by the major parties, with Thorvald Stauning as leader, and in July 1940 Erik Scavenius became foreign minister. When Germany attacked the Soviet Union, the Danish government was forced to allow the formation of a Danish volunteer corps and at the same time to forbid all communist activity in the country. In November 1941, Denmark signed the Anti-Comintern Pact.

Stauning died suddenly in May 1942 and was succeeded by Vilhelm Buhl, who, however, was forced to resign in November of the same year under pressure from the Germans. He was succeeded by Scavenius. The elections of 1943 proved to be a great national demonstration that the people were united in support of the four old democratic parties and the fight against Nazism. At the same time, the resistance movement was organized, and Germany's military defeats paved the way for demands for an open breach with the powers of occupation. Dissatisfaction caused by consumer shortages and inflation, combined with the growing opposition to German occupation, led

Danish resistance

to a series of strikes in the summer of 1943 that in August culminated in actions aimed directly at the Germans. When the Danish government refused to introduce the death penalty for sabotage, to allow the persecution of Jews, or to use force against the strikers, the Germans declared a state of emergency. The Danish government ceased to function and the German *Reichskommissioner* assumed political control. The Danish army and navy were disbanded, but not before many of the ships were scuttled by their own crews.

In September 1943 the Danish Freedom Council was formed, and under its leadership the resistance movement was organized, mainly in the form of illegal newspapers, a comprehensive intelligence service, and numerous acts of sabotage. During the last year of the war, closer cooperation began between the Freedom Council and leading politicians. When the Germans surrendered, on May 5, 1945, a government was formed consisting half of representatives of the Freedom Council and half of politicians from the old political parties. After elections in the autumn of 1945, a Left government came to power, led by Knud Kristensen.

The postwar period. The first task after the liberation was to initiate legal proceedings against German collaborators. By a retroactive law these persons were brought to trial and sentenced to death or given long prison sentences. Another consequence of the war was that the Schleswig question arose once more. The Nazi dictatorship and the great numbers of refugees fleeing from eastern Germany to South Schleswig caused a reaction that won the Danish faction strong support among the local population. In Denmark opinion was divided, but when the United Kingdom in the autumn of 1946 made inquiries about Denmark's opinion on the boundary, all the parties agreed in the October Note of 1946 to reject any alteration of the 1920 boundary. After the elections of 1947, when Kristensen's government was replaced by a Social Democratic minority government led by Hans Hedtoft, all plans to pursue an active policy concerning the boundary question were abandoned.

Defense policy. Denmark became a member of NATO in April 1949. Denmark's military defense later was considerably strengthened by statutes in 1950 and 1951 and was further complemented by armaments from the United States. Denmark nevertheless rejected a request by the United States to establish air bases on Danish territory. With West Germany's admission to NATO, Denmark succeeded in obtaining guarantees—confirmed in the Bonn Protocol of 1955—for the rights of the Danish minority in South Schleswig. (Jö.We.)

Political developments. The constitution was substantially revised in 1953: female succession to the throne was introduced, and the national legislature was reduced to one chamber, the Folketing, whose membership was increased to 179—including two seats for Greenland and two for the Faroe Islands—based on proportional representation. The wide spectrum of political parties made it almost impossible for any one party to secure a majority. As a result governments tended to be either minority governments or coalitions of two, three, or even four parties.

Four dominant political parties

The political scene was dominated by a core of four "old" parties: the Conservatives (Konservative Folkeparti), the Left (after 1964, the Liberal Party), the Radical Liberals, and the Social Democrats. A small and changing number of other parties, such as the Communists and the Justice Party (Retsforbundet; a single-tax party based on the ideas of Henry George), complicated the political and parliamentary situation.

From 1953 to 1968 the Social Democrats were in power, either alone or in coalition with the Radicals and, for a short period, the Justice Party, and always with a Social Democrat as prime minister. The major results were new tax laws: a general value-added consumer tax and income taxes deducted as earned were introduced, enabling the government to stimulate or restrain demand by lowering or raising the level of taxation.

In the 1968 election the majority shifted to the right. The Radical Liberals' leader, Hilmar Baunsgaard, deserted the Social Democrats and headed a coalition with the Conservatives and the Liberals until 1971, when Jens Otto Krag again formed a Social Democratic government.

On Jan. 14, 1972, King Frederick IX died, and his eldest daughter was proclaimed queen as Margrethe II.

The day after the referendum on Oct. 2, 1972, in which 63 percent of the voters approved Danish membership in the European Economic Community (EEC), Krag unexpectedly resigned, leaving the post of prime minister to Anker Jørgensen, who had to call an election in November 1973. An electoral landslide resulted in heavy losses for the four "old" parties and the emergence of three new parties: the Centre Democrats (Centrum-Demokraterne), the Christian People's Party (Kristeligt Folkeparti), and the Progress Party (Fremskridtspartiet), an antitax party. A weak minority government under Poul Hartling of the Liberal Party tried to solve the country's growing economic problems, but his austerity program resulted in protests from trade unions and the opposition. He appealed to the country in January 1975, but Jørgensen again came to power (from 1978 in coalition with the Liberals), rejecting support from the left-wing Socialist People's Party (Socialistisk Folkeparti), which opposed Danish membership in NATO.

The end of the 1970s brought a deteriorating economic situation and the political system's inability to reach a consensus on measures to solve the problems. Increased indirect taxes to reduce the foreign debt and the deficit on the balance of payments met with strong opposition from the trade unions; in 1979 Jørgensen was again forced to resign after the two parties had failed to agree on how to implement a price and income policy. After the election in October, however, he formed a Social Democratic minority government, which introduced what was called the most stringent wage-and-price-freeze program since World War II.

After a new general election in December 1981, the voting age having been reduced from 20 to 18 following a referendum, Jørgensen again lost seats in the Folketing, but he continued as leader of a weak minority government that faced many problems, especially high unemployment, which had risen to about 10 percent. He was once more forced to resign—this time, however, without an election—in September 1982. The leader of the Conservative Party, Poul Schlüter, formed a minority government with three other centre-right parties: the Liberals, the Centre Democrats, and the Christian People's Party. Together, they had only 66 seats in the Folketing.

The start of Schlüter's decade

Schlüter, the first Conservative prime minister since 1901, introduced a counterinflationary and economic recovery program that yielded results in 1985–86, but the country's foreign debt and balance-of-payments deficit continued to cause serious concern during the 1980s. Schlüter was consequently forced to call several general elections (1984, 1987, 1988), carry out government reshuffles (1986, 1987, 1988, 1989), and threaten to call elections or to resign. He survived 23 no-confidence votes concerning foreign and defense policy, brought by the Social Democrats in tactical attempts to force him from office.

When Schlüter reshuffled the government in 1988, he incorporated the Radical Liberals and excluded the Christian People's Party and the Centre Democrats. The coalition government came under greater pressure from the left-wing Socialist People's Party and the right-wing Progress Party, both of which gained seats in the Folketing at the end of the 1980s; the Progress Party advocated substantial cuts in the public sector and a more restrictive policy toward the dramatically increased number of refugees. It was a scandal over Tamil refugees that forced Schlüter's resignation in 1993 and brought a coalition government under the leadership of Social Democrat Poul Nyrup Rasmussen to power. The early 1990s also brought a gradual recovery in the Danish economy, despite the general European recession.

Economic issues. The domestic scene since the mid-20th century has been dominated by intermittently severe economic problems. From the 1950s onward the frequently negative balance of payments, the labour market, and the country's trade policy were troubling economic and political issues.

Imbalance of trade

Although during the early 1950s the Danish economy suffered a large deficit in the trade balance, the situation improved during the later 1950s as the result of lower import prices for raw materials, a considerable increase in industrial production, and the stabilization of prices of agricultural export products. The period from 1957 to 1965 saw rapidly rising prosperity. Within the framework of the Organisation for European Economic Co-operation (OEEC), Denmark, during the 1950s, abolished most of the regulations that had restricted its foreign trade, and it was one of the founding members of the European Free Trade Association (EFTA) in 1959. In 1972 Denmark was offered, and accepted, EEC membership, which became effective on Jan. 1, 1973.

During the 1960s, however, the balance-of-payments deficit became larger, and the government was forced to intervene in an attempt to control rising consumption. This was done by adding a purchase tax in 1962, by compulsory savings, by intervention in labour conflicts, and by the regulation of wages and prices. Economic problems worsened in the 1970s. The governments attempted to impose stringent measures such as harsh savings programs, but strong opposition to various plans led to the dissolution of the Folketing on several occasions. After 1973 rising oil prices and the international recession affected the Danish economy badly and led to a dramatic increase in unemployment.

In the 1980s the government was forced to impose several austerity measures which resulted in a record high level of taxation. The measures yielded results: lower inflation, recovery in business confidence and investments, growth of employment in the private sector, and increasing economic activity. It proved difficult, however, to eliminate the budget deficit, and in 1986 the government was forced to impose new austerity measures. Balance-of-payments deficits and persistent unemployment, however, continued to plague Denmark throughout the 1980s. (M.I.A.L./Ed.)

During the 1990s, while the economy improved and unemployment dropped, Danes struggled with three key political and economic issues. Political controversy surrounded the status of immigrants and refugees in Denmark. A violation of refugees' rights caused a conservative government to fall in 1993, right-wing parties adopted anti-immigration platforms, and rioting followed the expulsion in 1999 from Denmark of a Danish-born man of Turkish descent. While most Danes supported maintaining the country's strong social welfare programs, some Danes sought to decrease the programs' high cost in taxes, while others opposed any cuts in benefits. Danes also were divided during the 1990s over closer economic ties with the European Community. In 1992 Danish voters rejected the Maastricht Treaty, which provided the framework for an expanded European Union (EU) that would subsume the EC. A second referendum in 1993 approved Danish membership in the EU, but only after Denmark had negotiated exemptions from certain provisions of the treaty, which many Danes thought might erode Danish social benefits or environmental protections. In a 2000 referendum, Danish voters rejected the single European currency, the euro. Despite these controversies, Denmark's economy prospered at the turn of the 21st century, and the strength of its information and environmental technologies promised a bright future for the country. (Ed.)

BIBLIOGRAPHY

Physical and human geography: KENNETH E. MILLER (comp.), *Denmark* (1987), contains an annotated bibliography of various 19th- and 20th-century publications. ED THOMASSON, *Danish Quality Living: The Good Life Handbook* (1985), provides a casual introduction to how Danes sometimes describe themselves to foreigners. JUDITH FRIEDMAN HANSEN, *We Are a Little Land: Cultural Assumptions in Danish Everyday Life* (1980), describes the social and cultural values that characterize the Danish lifestyle as a distinctive variant of modern Euro-American civilization. ROBERT T. ANDERSON and BARBARA GALLATIN ANDERSON, *The Vanishing Village: A Danish Maritime Community* (1964), is an easy-to-read study of Danish life as it changed from that of a small inner-focused community to that of a mid-20th-century suburb of Copenhagen. CLEMENS PEDERSEN (ed.), *The Danish Co-operative Movement*, trans. from Danish (1977), offers an authoritative history of how Danish cooperatives first became influential in shaping the modernization of agriculture in Denmark and how they now function. THOMAS RØRDAM, *The Danish Folk High Schools*, 2nd rev. ed., trans. from Danish (1980), describes historically the movement initiated by N.S.F. Grundtvig that culminated in the folk high school movement as a means of putting education to the service of defining national goals of equality and self-respect for a peasant ancestry. ERIC S. EINHORN and JOHN LOGUE, *Modern Welfare States: Politics and Policies in Social Democratic Scandinavia* (1989), extensively describes and analyzes the expansion of the public sector in developing and managing the social welfare system that characterizes Denmark, Norway, and Sweden. ERIK ALLARDT *et al.*, *Nordic Democracy* (1981), is a well-documented, densely informative description of political institutions in Scandinavia. STANLEY V. ANDERSON, *The Nordic Council: A Study of Scandinavian Regionalism* (1967), a rather technical account from the perspective of political science and international law, studies how Danish communal values find expression through international cooperation with other Scandinavian nations.

History: General works include STEWART OAKLEY, *A Short History of Denmark* (also published as *The Story of Denmark*, 1972), a readable work; W. GLYN JONES, *Denmark: A Modern History*, rev. ed. (1986), a well-written survey; PALLE LAURING, *A History of Denmark*, 7th ed. (1986); and BENT RYING, *Danish in the South and the North*, vol. 2, *Denmark: History*, trans. from Danish (1988), which deals with the development from the Stone Age to present times, with excellent pictures. For more advanced studies, consult OLAF OLSEN (ed.), *Gyldendal og Politikens Danmarkshistorie* (1988–), with 7 vol. published by 1989; and the series "Dansk socialhistorie," 7 vol. (1979–82), on social history from the Stone Age to 1978—vol. 1 has appeared in an English trans. as *The Prehistory of Denmark*, by JØRGEN JENSEN (1982). Danish prehistory and archaeology are examined by PALLE LAURING, *Land of the Tollund Man* (1957; originally published in Danish, 1954), covering the first settlers of hunting nomads to the Vikings; P.V. GLOB, *Denmark: An Archaeological History from the Stone Age to the Vikings* (also published as *Danish Prehistoric Monuments*, 1971; originally published in Danish, 1942), a scholarly survey, *The Mound People: Danish Bronze-Age Man Preserved* (1974, reissued 1983; originally published in Danish, 1970), a thoroughly illustrated technical monograph, and *The Bog People: Iron Age Man Preserved* (1969, reissued 1988; originally published in Danish, 1965); and ELSE ROESDAHL, *Viking Age Denmark* (1982; originally published in Danish, 1980), an extensive description of Viking activities. RUTH MAZO KARRAS, *Slavery and Society in Medieval Scandinavia* (1988), draws on a wide variety of primary sources and archaeological data about the social, legal, and economic aspects of slavery. SVEND ELLEHØJ (ed.), *Christian IVs verden* (1988), correlates the findings and views of modern scholarship on the king and his times. SVEND AAGE HANSEN, *Økonomisk vækst i Danmark*, 2 vol. (1972–74), gives a broad view of the economic growth in the period 1720–1970, with statistics. FRIDLEV SKRUBBELTRANG, *Den danske Landbosamfund 1500–1800* (1978), concerns agriculture. JØRGEN HÆSTRUP, *Secret Alliance: A Study of the Danish Resistance Movement, 1940–1945*, 3 vol. (1976–77; originally published in Danish, 1954), analyzes the movement in detail, based on "illegal" documents and personal accounts by leading members of the Resistance. HARRY HAUE, JØRGEN OLSEN, and JØRN AARUP-KRISTENSEN, *Det ny Danmark 1890–1985: Udviklingslinjer og tendens*, 3rd ed. (1985), deals with modern history. For current research, three journals are useful: *The Scandinavian Economic History Review* (3/yr.); *Scandinavian Journal of History* (quarterly); and *Scandinavian Political Studies* (quarterly).

(R.T.A./S.V.A./M.I.A.L.)

The Great Depression

A worldwide economic downturn that began in 1929 and lasted until about 1939, the Great Depression was unique for its duration and for the number of countries it affected. It was the longest and most severe depression ever experienced by the industrialized Western world. Responses to the economic hardships of the era sparked fundamental changes in political and economic institutions, macroeconomic policy, and economic theory. Although it originated in the United States, the Great Depression caused drastic declines in output, severe unemployment, and acute deflation in almost every country of the world. Its social and cultural effects were no less staggering, especially in the United States, where the Great Depression represented the harshest adversity faced by Americans since the Civil War.

Economic history

The timing and severity of the Great Depression varied substantially across countries. The Depression was particularly long and severe in the United States and Europe; it was milder in Japan and much of Latin America. Perhaps not surprisingly, the worst depression ever experienced by the world economy stemmed from a multitude of causes. Declines in consumer demand, financial panics, and misguided government policies caused economic output to fall in the United States, while the gold standard, which linked nearly all the countries of the world in a network of fixed currency exchange rates, played a key role in transmitting the American downturn to other countries. The recovery from the Great Depression was spurred largely by the abandonment of the gold standard and the ensuing monetary expansion. The economic impact of the Great Depression was enormous, including both extreme human suffering and profound changes in economic policy.

Multiple causes

TIMING AND SEVERITY

The Great Depression began in the United States as an ordinary recession in the summer of 1929. The downturn became markedly worse, however, in late 1929 and continued until early 1933. Real output and prices fell precipitously. Between the peak and the trough of the downturn, industrial production in the United States declined 47 percent and real gross domestic product (GDP) fell 30 percent. The wholesale price index declined 33 percent (such declines in the price level are referred to as deflation). Although there is some debate about the reliability of the statistics, it is widely agreed that the unemployment rate exceeded 20 percent at its highest point. The severity of the Great Depression in the United States becomes especially clear when it is compared with America's next worst recession of the 20th century, that of 1981–82, when the country's real GDP declined just 2 percent and the unemployment rate peaked at less than 10 percent. Moreover, during the 1981–82 recession prices continued to rise, although the rate of price increase slowed substantially (a phenomenon known as disinflation).

Table 1: Dates of the Great Depression in Various Countries (in quarters)

country	depression began	recovery began
United States	1929:3	1933:2
United Kingdom	1930:1	1932:4
Germany	1928:1	1932:3
France	1930:2	1932:3
Italy	1929:3	1933:1
Japan	1930:1	1932:3
Canada	1929:2	1933:2
Belgium	1929:3	1932:4
The Netherlands	1929:4	1933:2
Sweden	1930:2	1932:3
Switzerland	1929:4	1933:1
Denmark	1930:4	1933:2
Poland	1929:1	1933:2
Czechoslovakia	1929:4	1933:2
Argentina	1929:2	1932:1
Brazil	1928:3	1931:4
India	1929:4	1931:4
South Africa	1930:1	1933:1

Global downturns in prices and production

The Depression affected virtually every country of the world. However, the dates and magnitude of the downturn varied substantially across countries. Table 1 shows the dates of the downturn and the upturn in economic activity in a number of countries. Table 2 shows the peak-to-trough percentage decline in annual industrial production for countries for which such data are available. Great Britain struggled with low growth and recession during most of the second half of the 1920s. Britain did not slip into severe depression, however, until early 1930, and its peak-to-trough decline in industrial production was roughly one-third that of the United States. France also experienced a relatively short downturn in the early 1930s. The French recovery in 1932 and 1933, however, was short-lived. French industrial production and prices both fell substantially between 1933 and 1936. Germany's economy slipped into a downturn early in 1928 and then stabilized before turning down again in the third quarter of 1929. The decline in German industrial production was roughly equal to that in the United States. A number of countries in Latin America fell into depression in late 1928 and early 1929, slightly before the U.S. decline in output. While some less-developed countries experienced severe depres-

sions, others, such as Argentina and Brazil, experienced comparatively mild downturns. Japan also experienced a mild depression, which began relatively late and ended relatively early.

The general price deflation evident in the United States was also present in other countries. Virtually every industrialized country endured declines in wholesale prices of 30 percent or more between 1929 and 1933. Because of the greater flexibility of the Japanese price structure, deflation in Japan was unusually rapid in 1930 and 1931. This rapid deflation may have helped to keep the decline in Japanese production relatively mild. The prices of primary commodities traded in world markets declined even more dramatically during this period. For example, the prices of coffee, cotton, silk, and rubber were reduced by roughly half just between September 1929 and December 1930. As a result, the terms of trade declined precipitously for producers of primary commodities.

The U.S. recovery began in the spring of 1933. Output grew rapidly in the mid-1930s: real GDP rose at an average rate of 9 percent per year between 1933 and 1937. Output had fallen so deeply in the early years of the 1930s, however, that it remained substantially below its long-run trend path throughout this period. In 1937–38 the United States suffered another severe downturn, but after mid-1938 the American economy grew even more rapidly than in the mid-1930s. The country's output finally returned to its long-run trend path in 1942.

A second economic downturn

Recovery in the rest of the world varied greatly. The British economy stopped declining soon after Great Britain abandoned the gold standard in September 1931, although genuine recovery did not begin until the end of 1932. The economies of a number of Latin American countries began to strengthen in late 1931 and early 1932. Germany and Japan both began to recover in the fall of 1932. Canada and many smaller European countries started to revive at about the same time as the United States, early in 1933. On the other hand, France, which experienced severe depression later than most countries, did not firmly enter the recovery phase until 1938.

CAUSES OF THE DECLINE

The fundamental cause of the Great Depression in the United States was a decline in spending (sometimes referred to as aggregate demand), which led to a decline in production as manufacturers and merchandisers noticed an unintended rise in inventories. The sources of the contraction in spending in the United States varied over the course of the Depression, but they cumulated in a monumental decline in aggregate demand. The American decline was transmitted to the rest of the world largely through the gold standard. However, a variety of other factors also influenced the downturn in various countries.

Stock market crash. The initial decline in U.S. output in the summer of 1929 is widely believed to have stemmed from tight U.S. monetary policy aimed at limiting stock market speculation. The 1920s had been a prosperous decade but not an exceptional boom period; prices had remained nearly constant throughout the decade, and there had been mild recessions in both 1924 and 1927. The one obvious area of excess was the stock market. Stock prices had risen more than fourfold from the low in 1921 to the peak in 1929. In 1928 and 1929 the Federal Reserve had raised interest rates in hopes of slowing the rapid rise in stock prices. These higher interest rates depressed interest-sensitive spending in areas such as construction and automobile purchases, which in turn reduced production. Some scholars believe that a boom in housing construction in the mid-1920s led to an excess supply of housing and a particularly large drop in construction in 1928 and 1929.

Excessive stock speculation

By the fall of 1929, U.S. stock prices had reached levels that could not be justified by reasonable anticipations of future earnings. As a result, when a variety of minor events led to gradual price declines in October 1929, investors lost confidence and the stock market bubble burst. Panic selling began on "Black Thursday," October 24, 1929. Many stocks had been purchased on margin—that is, using loans secured by only a small fraction of the stocks' value. As a result, the price declines forced some investors to liquidate their holdings, thus exacerbating the fall in prices. Between their peak in September and their low in November, U.S. stock prices (measured by the Cowles Index) declined 33 percent. Because the decline was so dramatic, this event is often referred to as the Great Crash of 1929.

The stock market crash reduced American aggregate demand substantially. Consumer purchases of durable goods and business investment fell sharply after the crash. A likely explanation is that the financial crisis generated considerable uncertainty about future income, which in turn led consumers and firms to put off purchases of durable goods. Although the loss of wealth caused by the decline in stock prices was relatively small, the crash may also have depressed spending by making people feel poorer. As a result of the drastic decline in consumer and business spending, real output in the United States, which had been declining slowly up to this point, fell rapidly in late 1929 and throughout 1930. Thus, while the Great Crash of the stock market and the Great Depression are two quite separate events, the decline in stock prices was one factor contributing to declines in production and employment in the United States.

Banking panics and monetary contraction. The next blow to aggregate demand occurred in the fall of 1930, when the first of four waves of banking panics gripped the United States. A banking panic arises when many depositors simultaneously lose confidence in the solvency of banks and demand that their bank deposits be paid to them in cash. Banks, which typically hold only a fraction of deposits as cash reserves, must liquidate loans in order to raise the required cash. This process of hasty liquidation can cause even a previously solvent bank to fail. The United States experienced widespread banking panics in the fall of 1930, the spring of 1931, the fall of 1931, and the fall of 1932. This final wave of panics continued through the winter of 1933 and culminated with the national "bank holiday" declared by President Franklin D. Roosevelt on March 6, 1933. The bank holiday closed all banks, and they were permitted to reopen only after being deemed solvent by government inspectors. The panics took a severe toll on the American banking system. By 1933, one-fifth of the banks in existence at the start of 1930 had failed.

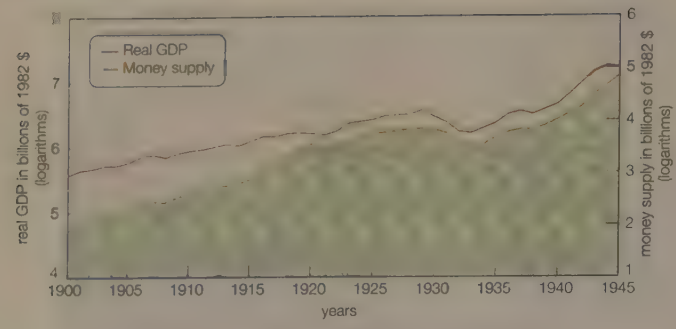
Runs on banks

By their nature, banking panics are largely irrational, inexplicable events, but some of the factors contributing to the problem can be explained. Economic historians believe that substantial increases in farm debt in the 1920s, together with U.S. policies that had encouraged small, undiversified banks, created an environment in which such panics could ignite and spread. The heavy farm debt stemmed in part from the high prices of agricultural goods during World War I, which had spurred extensive borrowing by American farmers wishing to increase production by investing in land and machinery. The decline in farm commodity prices following the war made it difficult for farmers to keep up with their loan payments.

The Federal Reserve did little to try to stem the banking panics. Economists Milton Friedman and Anna J. Schwartz, in the classic study *A Monetary History of the United States, 1867–1960* (1963), argued that the death in 1928 of Benjamin Strong, who had been the governor of the Federal Reserve Bank of New York since 1914, was a significant cause of this inaction. Strong had been a forceful leader who understood the ability of the central bank to limit panics. His death left a power vacuum at the Federal Reserve and allowed leaders with less sensible views to block effective intervention. The panics caused a dramatic rise in the amount of currency people wished to hold relative to their bank deposits. This rise in the currency-to-deposit ratio was a key reason why the money supply in the United States declined 31 percent between 1929 and 1933. In addition to allowing the panics to reduce the U.S. money supply, the Federal Reserve also deliberately contracted the money supply and raised interest rates in September 1931, when Britain was forced off the gold standard and investors feared that the United States would devalue as well.

Decline in the money supply

Scholars believe that such declines in the money supply caused by Federal Reserve decisions had a severely con-



Money and output in the United States, 1900–1945.

tractionary effect on output. A simple picture provides perhaps the clearest evidence of the key role monetary collapse played in the Great Depression in the United States. The figure shows the money supply and real output over the period 1900 to 1945. In ordinary times, such as the 1920s, both the money supply and output tend to grow steadily. But in the early 1930s both plummeted. The decline in the money supply depressed spending in a number of ways. Perhaps most important, because of actual price declines and the rapid decline in the money supply, consumers and businesspeople came to expect deflation; that is, they expected wages and prices to be lower in the future. As a result, even though nominal interest rates were very low, people did not want to borrow because they feared that future wages and profits would be inadequate to cover their loan payments. This hesitancy, in turn, led to severe reductions in both consumer spending and business investment spending. The panics surely exacerbated the decline in spending by generating pessimism and loss of confidence. Furthermore, the failure of so many banks disrupted lending, thereby reducing the funds available to finance investment.

Expectations of continued deflation

The gold standard. Some economists believe that the Federal Reserve allowed or caused the huge declines in the American money supply partly to preserve the gold standard. Under the gold standard, each country set the value of its currency in terms of gold and took monetary actions to defend the fixed price. It is possible that, had the Federal Reserve expanded the money supply greatly in response to the banking panics, foreigners could have lost confidence in the United States' commitment to the gold standard. This could have led to large gold outflows, and the United States could have been forced to devalue. Likewise, had the Federal Reserve not tightened in the fall of 1931, it is possible that there would have been a speculative attack on the dollar and the United States would have been forced to abandon the gold standard along with Great Britain.

While there is debate about the role the gold standard played in limiting U.S. monetary policy, there is no question that it was a key factor in the transmission of America's economic decline to the rest of the world. Under the gold standard, imbalances in trade or asset flows gave rise to international gold flows. For example, in the mid-1920s intense international demand for American assets such as stocks and bonds brought large inflows of gold to the United States. Likewise, a decision by France after World War I to return to the gold standard with an undervalued franc led to trade surpluses and substantial gold inflows. (See also TRADE, BALANCE OF in the *Micropædia*.)

Britain chose to return to the gold standard after World War I at the prewar parity. Wartime inflation, however, implied that the pound was overvalued, and this overvaluation led to trade deficits and substantial gold outflows after 1925. To stem the gold outflow, the Bank of England raised interest rates substantially. High interest rates depressed British spending and led to high unemployment in Great Britain throughout the second half of the 1920s.

Once the U.S. economy began to contract severely, the tendency for gold to flow out of other countries and toward the United States intensified. This took place because deflation in the United States made American goods particularly desirable to foreigners, while low income reduced American demand for foreign products. To counteract the resulting tendency toward an American trade surplus and foreign gold outflows, central banks throughout the world raised interest rates. Maintaining the international gold standard, in essence, required a massive monetary contraction throughout the world to match the one occurring in the United States. The result was a decline in output and prices in countries throughout the world that also nearly matched the downturn in the United States.

Effects of the gold standard

Financial crises and banking panics occurred in a number of countries besides the United States. In May 1931 payment difficulties at the Creditanstalt, Austria's largest bank, set off a string of financial crises that enveloped much of Europe and were a key factor forcing Britain to abandon the gold standard. Among the countries hardest hit by bank failures and volatile financial markets were Austria, Germany, and Hungary. These widespread banking crises could have been the result of poor regulation and other local factors or of simple contagion from one country to another. In addition, the gold standard, by forcing countries to deflate along with the United States, reduced the value of banks' collateral and made them more vulnerable to runs. As in the United States, banking panics and other financial market disruptions further depressed output and prices in a number of countries.

International lending and trade. Some scholars stress the importance of other international linkages. Foreign lending to Germany and Latin America had expanded greatly in the mid-1920s, but U.S. lending abroad fell in 1928 and 1929 as a result of high interest rates and the booming stock market in the United States. This reduction in foreign lending may have led to further credit contractions and declines in output in borrower countries. In Germany, which experienced extremely rapid inflation ("hyperinflation") in the early 1920s, monetary authorities may have hesitated to undertake expansionary policy to counteract the economic slowdown because they worried it might reignite inflation. The effects of reduced foreign lending may explain why the economies of Germany, Argentina, and Brazil turned down before the Great Depression began in the United States.

The 1930 enactment of the Smoot-Hawley tariff in the United States and the worldwide rise in protectionist trade policies created other complications. The Smoot-Hawley tariff was meant to boost farm incomes by reducing foreign competition in agricultural products. But other countries followed suit, both in retaliation and in an attempt to force a correction of trade imbalances. Scholars now believe that these policies may have reduced trade somewhat but were not a significant cause of the Depression in the large industrial producers. Protectionist policies, however, may have contributed to the extreme decline in the world price of raw materials, which caused severe balance-of-payments problems for primary-commodity-producing countries in Africa, Asia, and Latin America and led to contractionary monetary and fiscal policies.

SOURCES OF RECOVERY

Given the key roles of monetary contraction and the gold standard in causing the Great Depression, it is not surprising that currency devaluations and monetary expansion were the leading sources of recovery throughout the world. There is a notable correlation between the times at which countries abandoned the gold standard (or devalued their currencies substantially) and when they experienced renewed growth in their output. For example, Britain, which was forced off the gold standard in September 1931, recovered relatively early, while the United States, which did not effectively devalue its currency until 1933, recovered substantially later. Similarly, the Latin American countries of Argentina and Brazil, which began to devalue in 1929, experienced relatively mild downturns and had largely recovered by 1935. In contrast, the "Gold Bloc" countries of Belgium and France, which were particularly wedded to the gold standard and slow to devalue, still had industrial production in 1935 well below that of 1929.

Role of monetary policy

Devaluation, however, did not increase output directly. Rather, it allowed countries to expand their money supplies without concern about gold movements and ex-

change rates. Countries that took greater advantage of this freedom saw greater recovery. The monetary expansion that began in the United States in early 1933 was particularly dramatic. The American money supply increased nearly 42 percent between 1933 and 1937. This monetary expansion stemmed largely from a substantial gold inflow to the United States, caused in part by the rising political tensions in Europe that eventually led to World War II. Monetary expansion stimulated spending by lowering interest rates and making credit more widely available. It also created expectations of inflation, rather than deflation, thereby giving potential borrowers greater confidence that their wages and profits would be sufficient to cover their loan payments if they chose to borrow. One sign that monetary expansion stimulated recovery in the United States by encouraging borrowing was that consumer and business spending on interest-sensitive items such as cars, trucks, and machinery rose well before consumer spending on services.

Fiscal policy played a relatively small role in stimulating recovery in the United States. Indeed, the Revenue Act of 1932 increased American tax rates greatly in an attempt to balance the federal budget, and by doing so it dealt another contractionary blow to the economy by further discouraging spending. Franklin D. Roosevelt's New Deal, initiated in early 1933, did include a number of new federal programs aimed at generating recovery. For example, the Works Progress Administration (WPA) hired the unemployed to work on government building projects, and the Tennessee Valley Authority (TVA) constructed dams and power plants in a particularly depressed area. However, the actual increases in government spending and the government budget deficit were small relative to the size of the economy. This is especially apparent when state government budget deficits are included, because those deficits actually declined at the same time that the federal deficit rose. As a result, the new spending programs initiated by the New Deal had little direct expansionary effect on the economy. Whether they may nevertheless have had positive effects on consumer and business sentiment remains an open question.

Federal programs

Some New Deal programs may have actually hindered recovery. The National Industrial Recovery Act of 1933, for example, set up the National Recovery Administration (NRA), which encouraged firms in each industry to adopt a code of behaviour. These codes discouraged price competition between firms, set minimum wages in each industry, and sometimes limited production. Likewise, the Agricultural Adjustment Act of 1933 created the Agricultural Adjustment Administration (AAA), which set voluntary guidelines and gave incentive payments to farmers to restrict production in hopes of raising agricultural prices. Modern research suggests that such anticompetitive practices and wage and price guidelines led to inflation in the early recovery period in the United States and discouraged reemployment and production.

Recovery in the United States was stopped short by another distinct recession that began in May 1937 and lasted until June 1938. One source of the 1937–38 recession was a decision by the Federal Reserve to greatly increase reserve requirements. This move, which was prompted by fears that the economy might be developing speculative excess, caused the money supply to cease its rapid growth and to actually fall again. Fiscal contraction and a decrease in inventory investment due to labour unrest are also thought to have contributed to the downturn. That the United States experienced a second, very severe contraction before it had completely recovered from the enormous decline of the early 1930s is the main reason that the United States remained depressed for virtually the entire decade.

World War II played only a modest role in the recovery of the U.S. economy. Despite the recession of 1937–38, real GDP in the United States was well above its pre-Depression level by 1939, and by 1941 it had recovered to within about 10 percent of its long-run trend path. Therefore, in a fundamental sense, the United States had largely recovered before military spending accelerated noticeably. At the same time, the U.S. economy was still somewhat below trend at the start of the war, and the unemployment rate averaged just under 10 percent in 1941. The government budget deficit grew rapidly in 1941 and 1942 because of the military buildup, and the Federal Reserve responded to the threat and later the reality of war by increasing the money supply greatly over the same period. This expansionary fiscal and monetary policy, together with widespread conscription beginning in 1942, quickly returned the economy to its trend path and reduced the unemployment rate to below its pre-Depression level. So, while the war was not the main impetus for the recovery in the United States, it played a role in completing the return to full employment.

The role of fiscal expansion, and especially of military expenditure, in generating recovery varied substantially across countries. Great Britain, like the United States, did not use fiscal expansion to a noticeable extent early in its recovery. It did, however, increase military spending substantially after 1937. France raised taxes in the mid-1930s in an effort to defend the gold standard but then ran large budget deficits starting in 1936. The expansionary effect of these deficits, however, was counteracted somewhat by a legislated reduction in the French workweek from 46 to 40 hours—a change that raised costs and depressed production. Fiscal policy was used more successfully in Germany and Japan. The German budget deficit as a percent of domestic product increased little early in the recovery, but it grew substantially after 1934 as a result of spending on public works and rearmament. In Japan, government expenditures, particularly military spending, rose from 31 to 38 percent of domestic product between 1932 and 1934, resulting in substantial budget deficits. This fiscal stimulus, combined with substantial monetary expansion and an undervalued yen, returned the Japanese economy to full employment relatively quickly.

ECONOMIC IMPACT

The most devastating impact of the Great Depression was human suffering. In a short period of time, world output and standards of living dropped precipitously. As much as one-fourth of the labour force in industrialized countries was unable to find work in the early 1930s. While conditions began to improve by the mid-1930s, total recovery was not accomplished until the end of the decade.

The Great Depression and the policy response also changed the world economy in crucial ways. Most obviously, it hastened, if not caused, the end of the international gold standard. Although a system of fixed currency exchange rates was reinstated after World War II under the Bretton Woods system, the economies of the world never embraced that system with the conviction and fervour they had brought to the gold standard. By 1973, fixed exchange rates had been abandoned in favour of floating rates. (See also MONEY.)

Growth of labour unions

Both labour unions and the welfare state expanded substantially during the 1930s. In the United States, union membership more than doubled between 1930 and 1940. This trend was stimulated by both the severe unemployment of the 1930s and the passage of the National Labor Relations (Wagner) Act (1935), which encouraged collective bargaining. The United States also established unemployment compensation and old-age and survivors' insurance through the Social Security Act (1935), which was passed in response to the hardships of the 1930s. It is uncertain whether these changes would have eventually occurred in the United States without the Great Depression. Many European countries had experienced significant increases in union membership and had established government pensions before the 1930s. Both of these trends, however, accelerated in Europe during the Great Depression.

In many countries, government regulation of the economy, especially of financial markets, increased substantially in the 1930s. The United States, for example, established the Securities and Exchange Commission (1934) to regulate new stock issues and stock market trading practices. The Banking Act of 1933 (also known as the Glass-Steagall Act) established deposit insurance in the United States and prohibited banks from underwriting or dealing in securi-

ties. Deposit insurance, which did not become common worldwide until after World War II, effectively eliminated banking panics as an exacerbating factor in recessions in the United States after 1933.

The Great Depression also played a crucial role in the development of macroeconomic policies intended to temper economic downturns and upturns. The central role of reduced spending and monetary contraction in the Depression led British economist John Maynard Keynes to develop the ideas in his *General Theory of Employment, Interest, and Money* (1936). Keynes's theory suggested that increases in government spending, tax cuts, and monetary expansion could be used to counteract depressions. This insight, combined with a growing consensus that government should try to stabilize employment, has led to much more activist policy since the 1930s. Legislatures and central banks throughout the world now routinely attempt to prevent or moderate recessions. Whether such a change would have occurred without the Depression is again a largely unanswerable question. What is clear is that this change has made it unlikely that a decline in spending will ever be allowed to multiply and spread throughout the world as it did during the Great Depression of the 1930s.

Stabilization policy

(C.D.Ro.)

Culture and society in the Great Depression

No decade in the 20th century was more terrifying for people throughout the world than the 1930s. The traumas of the decade included economic disorder, the rise of totalitarianism, and the coming (or presence) of war. Nevertheless, the decade is remembered in different ways in different parts of the world. For people in the United States, the 1930s was indelibly the age of the Great Depression. Bank panics destroyed faith in the economic system, and joblessness limited faith in the future. The worst drought in modern American history struck the Great Plains in 1934. Windstorms that stripped the topsoil from millions of acres turned the whole area into a vast Dust Bowl and destroyed crops and livestock in unprecedented amounts. As a result, some 2.5 million people fled the Plains states, many bound for California, where the promise of sunshine and a better life often collided with the reality of scarce, poorly paid work as migrant farm labourers.

For Americans, the 1930s will always summon up images of breadlines, apple sellers on street corners, shuttered factories, rural poverty, and so-called Hoovervilles (named for President Herbert Hoover), where homeless families sought refuge in shelters cobbled together from salvaged wood, cardboard, and tin. It was a time when thousands of teens became drifters; many marriages were postponed and engagements were interminable; birth rates declined; and children grew up quickly, often taking on adult responsibilities if not the role of comforter to their despondent parents. It was a time when the number of women in the workplace actually increased, which helped needy families but only added to the psychological strain on the American male, the traditional "breadwinner" of the American family. It was a time when one of the most popular tunes was "Brother, Can You Spare a Dime?"

GLOBAL CONCERNS

The memories of Europeans, by contrast, are haunted not by their economic difficulties, which were considerable, but by the spectre of Adolf Hitler and his drive to conquer the European continent. The Great Depression, of course, had created the perfect environment—political instability and an economically devastated and vulnerable populace—for the Nazi seizure of power and fascist empire building. Consequently, it was the spread of totalitarianism and not economic hardship that occupied the minds of Europeans in the 1930s. The situation was similar in Asia, where urban and rural penury was a normal feature of economic life; moreover, the decade of the 1930s is forever linked to the spread and brutality of Japanese imperialism. Thus, while Americans were preoccupied through most of the decade with their own domestic hardships, Europeans and Asians had other, more transnational, problems to confront.

The spread of totalitarianism

Moreover, the distinctive economic dilemmas of the 1930s were novel to Americans, largely because their historical experiences were so dissimilar from those of people in the rest of the world. For example, when British author George Orwell published *The Road to Wigan Pier* in 1937, he was describing an old problem: the class structure and its immemorial effect on workers in Britain. But when American authors such as Edmund Wilson or John Steinbeck wrote about the shut-down assembly lines in Detroit or the exodus of the Okies (Oklahomans displaced by the Dust Bowl) to California, they were describing something new: the near-total breakdown of a previously affluent economy. Americans were absorbed by their "Great Depression" because they had never before encountered such a widespread economic failure. This is why they, unlike their foreign counterparts, did not even begin to think about the approach of war or the dangers of totalitarianism until the end of the 1930s.

But no matter how insular Americans were through much of the decade, the world arrived on their shores in the 1930s. At the moment that Americans were worrying about their economy, European intellectuals, scientists, scholars, artists, and filmmakers were literally running for their lives. Where a lot of them ran was to the United States.

The most important event in the history of European culture in the 1930s was this massive hemorrhage of talent. No one was more responsible for transforming the cultural balance of power between Europe and the United States than Hitler. From the moment he assumed power in Germany in 1933, his book burnings, his firing of Jewish scholars in German universities, his assault on modern art, and his conquest of Europe at the end of the decade forced the most illustrious members of the European intelligentsia to flee, many of them first to France, then to the United States. Even a partial roster of émigrés to America in the 1930s is extraordinary. Among the natural scientists (most of whom were instrumental in constructing the atom bomb) were Albert Einstein, Enrico Fermi, Edward Teller, Leo Szilard, and Hans Bethe. The social scientists included Erik Erikson, Hannah Arendt, Erich Fromm, Paul Lazarsfeld, and Theodor Adorno. Philosophers such as Paul Tillich and Herbert Marcuse also emigrated, as did novelists and playwrights such as Thomas Mann, Vladimir Nabokov, and Bertolt Brecht. Musicians and composers included Igor Stravinsky, Béla Bartók, Arnold Schoenberg, Paul Hindemith, and Kurt Weill. Among the architects were Walter Gropius and Ludwig Mies van der Rohe. Painters and sculptors left too, notably Marc Chagall, Piet Mondrian, and Marcel Duchamp. And among those who found a home in (and helped to change) Hollywood were Fritz Lang and Billy Wilder—not to mention the Hungarian director Michael Curtiz, whose legendary *Casablanca* (1942) was in part a tribute to European refugee actors from Peter Lorre to Ingrid Bergman.

Emigration of European intelligentsia

Notably, not all persons seeking entry to the United States as refugees from Hitler's Germany were outstanding scholars, artists, scientists, or musicians. Most were average Europeans, but throughout the 1930s Congress chose not to liberalize the immigration laws to allow for more than the minimum quota of arrivals.

As a result of the massive intellectual and artistic emigration, by the end of the 1930s New York City and Hollywood had replaced Paris and Vienna as the home of Western culture—just as Washington would replace London and Berlin as the centre of Western politics and diplomacy at the end of World War II. To comprehend the America that became a postwar superpower, culturally as well as politically, it is necessary to understand how the United States responded to and emerged from its own singular experiences of the Great Depression in the 1930s.

POLITICAL MOVEMENTS AND SOCIAL CHANGE

Aside from the Civil War, the Great Depression was the gravest crisis in American history. Just as in the Civil War, the United States appeared—at least at the start of the 1930s—to be falling apart. But for all the turbulence and the panic, the ultimate effects of the Great Depression were less revolutionary than reassuring.

This was undeniably an era of extraordinary political innovation, much of it expressed in the reforms enacted by Franklin D. Roosevelt's New Deal and his administration's attempts to cope with the problems of poverty, unemployment, and the disintegration of the American economy. It was also a time when a significant number of Americans flirted with Marxist movements and ideas, as well as with the notion that the model for a more humane society could be found in the Soviet Union. Above all, it was a decade of cultural ferment, in which American writers, artists, and intellectuals experimented with new, more socially oriented forms of literature, painting, theatre, music, and mass entertainment.

Yet, paradoxically, the turmoil of the 1930s turned out to be predominantly conservative in its impact on American society. The Great Depression taught people of all social classes the value of economic security and the need to endure and survive hard times rather than to take risks with one's life or money. Moreover, faced with the spectre of totalitarian ideologies in Europe and Japan, Americans rediscovered the virtues of democracy and the essential decency of the ordinary citizen—the near-mythical "common man" who was celebrated in Roosevelt's speeches, Frank Capra's movies, and Norman Rockwell's paintings. Thus, a decade marked by fundamental—even radical—social change ended for most with a reaffirmation of America's cultural past and its traditional political ideals.

By contrast, many American intellectuals in the 1920s, disillusioned by what they considered the pointless carnage of World War I, had shown little interest in politics or social movements. Nor did they display much affection for life in the United States. Indeed, most American novelists, poets, artists, composers, and scientists continued to believe, as they had since the 19th century, that the United States was culturally inferior to Europe. So, to learn the latest modernist techniques in literature, painting, or music or to study the most advanced theories in physics or psychoanalysis, they assumed they had to go to London, Paris, Berlin, Vienna, or Copenhagen.

But the stock market crash in 1929, the factory closures and spiraling unemployment of the early 1930s, and Hitler's takeover of the German government in 1933 forced many "expatriates" not only to return to the United States but to become politically engaged in their home country. During the worst years of the Great Depression, between 1930 and 1935, this engagement often took the form of an attraction to Marxism, the Soviet Union, and the American Communist Party.

The appeal of Marxism

Marxism seemed to explain persuasively the causes of capitalism's collapse while also providing a vision of an alternative social order. The Soviet Union, the site of the first successful Marxist-inspired revolution, appeared by the 1930s to be a concrete embodiment of what many writers called (in characteristically pragmatic American terms) the socialist "experiment." In addition, from 1934 to 1939, the Soviet Union was the most uncompromising opponent of Nazi Germany, seeking alliances with Britain, France, and the United States and promoting a "popular front" partnership of liberals and socialists within the Western democracies to halt the spread of fascism in Europe and throughout the world. Nowhere did Moscow's desire for a broad antifascist coalition appear more genuine than in the Spanish Civil War (1936–39), when the Soviet Union was the only country besides Mexico to aid in any serious way the Spanish Republicans against the armies of Francisco Franco (supported by Hitler and Benito Mussolini).

Meanwhile, the communist parties in the United States and in western Europe gave intellectuals—as well as teachers, lawyers, architects, and other middle-class professionals—a feeling that they were no longer solitary individuals suffering from the failures of capitalism but belonged instead to a vibrant community of like-minded souls, in that they were participants in an international movement larger than themselves and that they were literally making history. For all these reasons Marxism, the Soviet Union, and the various national communist parties enjoyed a prestige and a popularity through much of the 1930s that they had never possessed in the 1920s and would never again enjoy after the Great Depression.

In 1932 the appeal of Marxism led 53 prominent American writers—including the novelists Sherwood Anderson and John Dos Passos, poet Langston Hughes, literary critics Edmund Wilson and Malcolm Cowley, philosopher Sidney Hook, and journalist Lincoln Steffens—to announce their support for William Z. Foster, the Communist Party's candidate for president. Although Dos Passos, Wilson, and Hook later became bitter critics of the Soviet Union's Stalinist regime (see STALINISM in the *Micropædia*), their initial enthusiasm for a socialist revolution indicated how compelling for intellectuals were the values and ideas of the left.

Perhaps no writer better reflected this new sense of social commitment than Ernest Hemingway. In 1929 Hemingway published *A Farewell to Arms*. The novel's Lieutenant Henry, like Hemingway himself a volunteer American ambulance driver in Italy during World War I, decides to flee the madness of the war and make a "separate peace." Here, desertion is seen as an act of sanity, even of heroism. Eleven years later, in 1940, Hemingway published another novel about war—in this case, the Spanish Civil War—called *For Whom the Bell Tolls* (the title was taken from John Donne's poem, which is itself a hymn to human fellowship). In this novel, Robert Jordan, another Hemingwayesque volunteer, serving with a band of anti-Franco guerrillas, is badly wounded but stays behind to defend a bridge, thereby protecting his comrades as they retreat. Jordan—unlike Lieutenant Henry—has found a cause worth fighting and dying for. And Hemingway's own strong identification with the Spanish Republicans, for whom he raised money and helped make a documentary film called *The Spanish Earth* (1937), was symptomatic of a political involvement that neither he nor his fictional characters would have undertaken a decade earlier.

Hemingway's social commitment

Of course, not every Depression-era American writer was entranced by communism or the Soviet Union. The majority of intellectuals and artists, like their fellow citizens, were much more comfortable voting for Roosevelt than idolizing Joseph Stalin. Indeed, by the middle and late 1930s, a growing number of American intellectuals—many of them clustered around the literary and political journal *Partisan Review*—had become militantly anti-Stalinist even as they retained their sympathy for socialism, their new stance having formed as Stalin launched a series of show "trials" that sent his former Bolshevik colleagues to Siberian labour camps (or more frequently to their death in the cellars of prisons), as terror spread throughout the Soviet Union, and as stories began to circulate about the communists murdering Trotskyists and anarchists behind the Republican lines in Spain. Still, it was not until August 1939, when Stalin shocked the world by signing a nonaggression pact with his archenemy Hitler that the Soviet Union and the Communist Party in the United States lost what was left of their moral authority with all but a few American intellectuals.

NEW FORMS OF CULTURAL EXPRESSION

The documentary impulse. Novelists, poets, painters, and playwrights of the 1930s did not need to be Marxists to create works that dealt with the problems of the Great Depression or the dangers of fascism. Indeed, even many who were sympathetic to Marxism acted as "fellow travelers" without joining the Communist Party. Most writers and artists in the prosperous 1920s thought of themselves as members of a transatlantic avant-garde and as stylistic disciples of Pablo Picasso, James Joyce, or Igor Stravinsky. In the impoverished and desperate 1930s, they repudiated—as did Malcolm Cowley in his literary memoir of the 1920s, *Exile's Return* (1934)—what they now regarded as the escapism and self-indulgence of their modernist mentors. Given the political and economic calamities at home and abroad, they sought to focus on the plight of workers, sharecroppers, African Americans, the poor, and the dispossessed. Further, they wanted to communicate their insights in a language—whether literary, visual, or musical—that their audiences could easily comprehend.

This impulse led, in a variety of genres, to an aesthetic of documentary-style realism and of social protest. For writers such as Edmund Wilson, Sherwood Anderson, John

Dos Passos, Erskine Caldwell, Richard Wright, and James Agee, fiction seemed inadequate in describing the disastrous effects of the Great Depression on political institutions, the natural environment, and human lives. So they joined with photographers and turned to journalism, as if their eyewitness portraits of desolate factories and American shantytowns, interviews with migrant workers and tenant farmers, and ubiquitous cameras could capture the "feel" and the essential truth of the Great Depression. Their yearning to record the pure, unadorned facts of daily existence, to listen to what Americans said about their plight, and to refrain from abstract theories or artistic embellishment was reflected in the titles of some of the books they wrote about their travels throughout the country: Wilson's *The American Jitters* (1932), Anderson's *Puzzled America* (1935), Nathan Asch's *The Road—In Search of America* (1937), Caldwell's *You Have Seen Their Faces* (1937), and Wright's *Twelve Million Black Voices* (1941).

Let Us Now Praise Famous Men

The most lyrical, and certainly the most eccentric, of these documentaries was *Let Us Now Praise Famous Men* (1941), with a text by Agee and pictures by Walker Evans. In order to illuminate the suffering but also the dignity of three sharecropper families in Alabama, Evans tried to photograph his subjects as objectively and as unobtrusively as possible. Meanwhile, Agee employed a variety of journalistic and artistic techniques: naturalistic description and dialogue, an almost anthropological itemization of clothing and household furniture, erudite discussions of agricultural problems in the Deep South, autobiographical ruminations, religious symbolism, and intimate expressions of love for the families and rage at their misery. Though the book's prose was perhaps too convoluted for readers in 1941, *Let Us Now Praise Famous Men* was the precursor of what would later be called the "new journalism," a highly personal style of reporting that influenced writers as diverse as George Orwell, Truman Capote, Tom Wolfe, and Norman Mailer.

Increasingly, Americans expected to be transported—through photos, newsreels, or radio—to the scene of the latest calamity. The urge to convey the sights and sounds of the 1930s was also reflected in the emergence of public-opinion polling as a major (if still primitive) industry, in the "living newspaper" productions of the Works Progress Administration (WPA) Federal Theatre Project that dramatized the headlines of the day, in government-sponsored documentary films such as Pare Lorentz's *The River* (1938) and *The Plow That Broke the Plains* (1936), in newsreels such as Twentieth Century Fox's Movietone News and Henry Luce's *March of Time*, in the photography of Dorothea Lange and Margaret Bourke-White, and in *Life* magazine's reliance on photographs even more than on traditional print journalism to tell the authentic story of what Americans were enduring at the time.

This sensation of being present, at least vicariously, at a crisis may explain why Orson Welles's radio adaptation on October 30, 1938, of H.G. Wells's *War of the Worlds* terrified so many listeners into believing that Martians had actually landed in New Jersey. The broadcast was done not as a play but in the style of a news story, with "announcers" breaking in for special bulletins, "reporters" delivering on-the-spot descriptions of the invasion, and "government spokesmen" (including one who sounded like FDR) issuing orders to troops and police. It was an event shared by millions of Americans, which is why it remains one of the most remembered events of the 1930s.

By the end of the decade, as Europe erupted into war, dramatic radio broadcasts took their cue from Welles's drama, and audiences grew to depend on a new type of foreign correspondent such as Edward R. Murrow, who broadcast from Berlin, Paris, or the rooftops of London and brought the sounds of falling bombs and air-raid sirens directly into people's living rooms, documenting a global struggle more cataclysmic than even Welles could have imagined.

Federal arts programs. The Roosevelt administration, too, embraced the notion that writers and artists should immerse themselves in the details, past and present, of American life. The United States, however, lacked a strong tradition of direct federal support for the arts. This may have been due to the public suspicion of such funding, especially during the 1930s, amid the spectacle of the Nazis' torchlight parades and their total control over radio and movies in Germany, which worried some U.S. congressmen and senators, as well as ordinary citizens, about the capacity of governments to use culture to manipulate public opinion. It was therefore both unprecedented and remarkable that between 1935 and 1939 the Roosevelt administration was able to create and sustain the Federal Art Project, the Federal Music Project, the Federal Writers' Project, and the Federal Theatre Project as part of the WPA.

The New Deal rationale for these cultural endeavours was that—just like construction workers—writers, musicians, painters, and actors had to eat and, more important, to use their skills for the benefit of society. Consequently, the Federal Theatre Project performances were staged not on Broadway but in working-class and African American neighbourhoods, outside factory gates, and in small towns whose residents had never seen a play. The Federal Writers' Project arranged for thousands of interviews with blue-collar workers, small farmers, fishermen, miners, lumberjacks, waitresses, and former slaves, and it published guidebooks that explored the history, ethnic composition, folklore, and ecology of every state. The Federal Music Project sponsored free concerts and the musical transcription of half-forgotten sea chanteys, cowboy and folk songs, Indian dances, Quaker hymns, and Negro spirituals. The Federal Art Project funded art education, established art centres, and made it possible for thousands of artists to complete works in sculpture, painting, and graphic arts; in addition, the Public Works of Art Project, influenced by Mexican painters such as José Clemente Orozco and Diego Rivera, arranged for murals to be painted on the walls of post offices and county courthouses depicting the stories of particular regions and local communities. It was precisely this attraction to traditional American melodies and to Norman Rockwell-like illustrations of ordinary life that helped composers such as Aaron Copland and Virgil Thomson and painters such as Thomas Hart Benton and Ben Shahn, all of them trained in the European modernist aesthetics of Stravinsky or Picasso, to adapt avant-garde techniques to "American" themes and hence offer an art accessible to popular taste.

The Federal Writers' Project

Theatre. None of this means that in the 1930s novelists abandoned fiction or that playwrights ignored the theatre. Rather, many writers still wanted to invest contemporary issues with poetic as well as political power, to raise brute facts to the level of art. Some, influenced by the Soviet Union's call for Socialist Realism, tried to create a didactic "proletarian" literature that usually chronicled a young, politically innocent worker's discovery of the need to join the labour movement, if not the Communist Party. This formula, with its melodramatic tale of how the exploited could triumph over the bosses, frequently led to wooden or bombastic prose, both in novels and on the stage.

Still, there were a number of theatrical companies in addition to the Federal Theatre—such as the Theatre Union and Orson Welles's Mercury Theatre—that attempted to put on plays that were artistically challenging as well as socially relevant. No company was more successful in this effort than the aptly named Group Theatre. Founded in 1931 by the directors Harold Clurman, Lee Strasberg, and Cheryl Crawford and featuring actors such as Stella Adler, John Garfield, Franchot Tone, Lee J. Cobb, Karl Malden, and Elia Kazan, the Group Theatre survived throughout the Great Depression in New York City as a noncommercial repertory company without stars or prima donnas, devoted to plays of current significance, and emphasizing a psychologically realistic acting style known as the Method, which Clurman and Strasberg borrowed from the ideas Konstantin Stanislavsky pioneered during his reign as director of the pre-Bolshevik Moscow Art Theatre.

The Group Theatre

In 1935 the Group's leading playwright, Clifford Odets, wrote a one-act play whose title could not have summed up more accurately the political sentiments of the 1930s: *Waiting for Lefty*. This was the quintessential proletarian drama in which the actors and the audience on opening night arose at the end of the play to demonstrate their solidarity with New York City taxi drivers by chanting "Strike! Strike! Strike!"

While some continue to see the Group's political engagement as its enduring hallmark, its true legacy lay not in its ideology but in its impact on American acting, especially on the screen. After World War II, under the influence of Strasberg, Adler, and Kazan, actors who trained in the Method—Marlon Brando, James Dean, Meryl Streep, Paul Newman, Robert De Niro, Al Pacino, Dustin Hoffman, and Shelley Winters, among others—became the most emotionally compelling performers in American movies.

Fiction. The social consciousness of the theatre was duplicated in some of the widely read novels of the 1930s. Here, too, authors strove for a fidelity to the sombre facts of the Depression experience. James T. Farrell's *Studs Lonigan* trilogy (1932, 1934, 1935) explored the claustrophobic world of lower-middle-class Irish Catholics, while Richard Wright's *Native Son* (1940) offered a harrowing portrait of a young African American man imprisoned in white America, capable of asserting his identity only through fear-drenched acts of violence.

It was this sense of constriction, the fear of shrinking natural and economic resources, the feeling that America was no longer buoyant and youthful—no longer a land of infinite hope and opportunity—that captured the mood of the 1930s and underlay the message of many of its novels. John Dos Passos's trilogy *U.S.A.* (1930, 1932, 1936)—a "multimedia history" of the United States in the first three decades of the 20th century, weaving together newspaper headlines, popular songs, biographies of celebrities, fictional stories, and eloquent prose-poems—was unrelenting in its sardonic depiction of American lives wasted in the neurotic pursuit of wealth and success. John Steinbeck's

The Grapes of Wrath

The Grapes of Wrath (1939), the most illustrious "protest" novel of the 1930s, was an epic tribute to the Okies, those throwbacks to America's 19th-century pioneers, now run off their farms by the banks, the Dust Bowl, and the mechanization of modern agriculture, clattering in their trucks and jalopies across the Arizona desert on Route 66 to the advertised promised land in California, a despised caste of migrant labourers who (like Steinbeck's heroic earth mother, Ma Joad) still insisted that the "people" are indestructible no matter what tragedies they must surmount.

But California might not have been a place for new beginnings; in the 1930s, as the novelist Nathanael West observed in *The Day of the Locust* (1939), it was more likely a destination where people went to die. In this novel, as well as in *Miss Lonelyhearts* (1933), West—in his fascination with bizarre personalities and psychological breakdowns—may well have expressed the deeper literary preoccupations of the 1930s more perceptively than did Wright or Steinbeck, preoccupations also reflected in John O'Hara's *Appointment in Samarra* (1934) and Horace McCoy's *They Shoot Horses, Don't They?* (1935).

Apolitical writers

Like West, the finest and most idiosyncratic writers of the decade—Thomas Wolfe, who was obsessed with dramatizing his own life in *Look Homeward, Angel* (1929); F. Scott Fitzgerald, whose *Tender Is the Night* (1934) and *The Last Tycoon* (1941) contained passages of prose as haunting as anything one could find in *The Great Gatsby* (1925); and William Faulkner, whose *The Sound and the Fury* (1929), *Light in August* (1932), and *Absalom, Absalom!* (1936) would appear on any list of the great American novels of the 20th century—did not conform to the formulas of protest or the demands of any creed. Their novels were not optimistic or pessimistic about America, nor were they "radical" or "conservative." More often, they were apolitical. Each of these authors strove not for a timely discussion of the social problems of the Great Depression years but for a timeless meditation on the agonies of life, love, and death. This sensitivity to private human predicaments, or more specifically to what might happen over a lifetime to husbands and wives and children in a small fictional New England village called Grover's Corners, was also why Thornton Wilder's *Our Town* (1939), not *Waiting for Lefty*, came to be the most treasured and enduring play of the 1930s. Such novels and plays—romantic, confessional, disturbing—would still be read or performed long after the proletarian aesthetic had lost its appeal for most Americans.

Popular culture. The indifference to politics and to the larger social concerns of the 1930s was reflected as well in the popular culture of the decade. In contrast to the prosperity of the Roaring Twenties, the 1930s emphasized simplicity and thrift. Although styles tended to reflect the glamour of contemporary movies, clothes themselves were mended before being replaced, and the invention of synthetic fibres led to the use of washable, practical, easy-care fabrics. Many who could not afford books or periodicals spent time reading in libraries. Inexpensive amusements included backyard games, puzzles, card games, and board games such as Monopoly, which was introduced in 1935. Even the national pastime, baseball, changed profoundly during the Great Depression. Major league rosters and players' salaries were cut, 14 minor leagues were eliminated, and, in an effort to bolster attendance that had fallen by more than 40 percent by 1933, night games were introduced. And with the end of Prohibition in 1933, nightclubs became legitimate places not only to consume liquor but to socialize, dance, enjoy the entertainment, and be seen wearing the latest fashions. Because radio and film reached many more people than novels or plays, some intellectuals believed that the mass media might be the most effective weapon for radicalizing Americans. Yet, predictably, the radio networks and the Hollywood studios, as commercial enterprises, were more interested in entertaining than in indoctrinating the masses.

Thus, the most popular programs on radio were afternoon soap operas, music and variety broadcasts, and half-hour comedy shows like *Amos 'n' Andy*, *The Jack Benny Program*, and *The Edgar Bergen/Charlie McCarthy Show*. Although Hollywood was filled with people sympathetic to the political left—people who frequently contributed money to the labour movement or the Spanish Republicans or who were indispensable in organizing the Screen Actors, Writers, and Directors guilds—little of this political activism left an imprint on the screen.

Hollywood's response

In fact, it is striking how few American movies during the 1930s dealt with the plight of the poor and the unemployed. The most memorable films of the decade (particularly those made at Metro-Goldwyn-Mayer, Paramount, and Twentieth Century Fox) were musicals, screwball comedies, and romances. Only Warner Brothers specialized in movies, usually gangster sagas, about the violence and poverty of slum life, a life the embattled hoodlum protagonists always yearned to escape.

What many of Hollywood's movies really had in common—even the spectacles of director Busby Berkeley and the dazzling duets of Fred Astaire and his frequent partner Ginger Rogers—was a soundtrack peppered with hard-boiled, even cynical, staccato chatter reminiscent of Walter Winchell's gossip columns in the newspapers and on the radio. The fast-talking guys and dames of 1930s movies—like the contemporaneous music and lyrics of George Gershwin and Ira Gershwin, Cole Porter, Irving Berlin, and Richard Rodgers and Lorenz Hart—were the product of a culture both urban and urbane; the movies and the music depended on clever allusions and witty dialogue, written or composed mostly by sophisticated Manhattanites. One could never imagine Cary Grant, Fred Astaire, Katharine Hepburn, Bette Davis, Rosalind Russell, Claudette Colbert, or the Marx Brothers portraying rural hayseeds or working stiffs. Nor was it possible to envision the gangsters, as played by Edward G. Robinson or James Cagney, asking passing strangers if they could spare a dime. The characters they played all lived in a world of posh furniture and polished floors, of well-cut suits and gowns, of elegant nightclubs filled with cigarette smoke and champagne and piano music, a world far removed from the one movie audiences inhabited.

Some of the music of the 1930s tried to assuage the social suffering. Indeed, from Lew Brown and Ray Henderson's "Life Is Just a Bowl of Cherries" (1931) to Al Dubin and Harry Warren's "We're in the Money" (1933), many of the era's popular songs were suffused in buoyant optimism. The emphatic "Happy Days Are Here Again" (1929) could be heard just about anywhere, whether as a political jingle for Roosevelt's 1932 presidential campaign or as the theme song for the *Your Hit Parade* radio show, launched in

1935. By mid-decade the Benny Goodman Orchestra had ushered in the swing era, popularizing a style of big band jazz that had been pioneered a decade earlier by African American ensembles led by Fletcher Henderson and Duke Ellington. Dance-oriented and relentlessly upbeat, swing was not a palliative for hopelessness; it was a tonic for recovery.

Yet songs that expressed a loss of faith in the American Dream were not completely absent. While Bing Crosby could sing "Just remember that the sunshine always follows the rain" in 1931 in "Wrap Your Troubles in Dreams," that same year he also recorded "Brother, Can You Spare a Dime?" Folk songs from the period, many recorded as part of the Federal Music Project's archival work, provide an especially vivid index of the deprivation suffered by ordinary Americans. Among the folksingers "discovered" through the field recordings of folklorists such as John Lomax and Alan Lomax was Leadbelly (Huddie Ledbetter), an ex-convict who gained fame for the songs he wrote about African American life during the Great Depression. No folk singer-songwriter, however, is more inextricably linked to the music of hardship and protest than Woody Guthrie. An Oklahoman, he took to the road at the height of the Dust Bowl era, frequenting hobo and migrant camps on his way to California, where he first popularized his songs about the plight of Dust Bowl refugees. With politically charged songs such as "(If You Ain't Got the) Do Re Mi," "Union Made," "Tom Joad" (inspired by *The Grapes of Wrath*), and "This Land Is Your Land," Guthrie became a mythic figure who continued his support of labour and radical politics (including his involvement with the Communist Party) long after most American intellectuals had abandoned them. In the process he became not only a catalyst for the folk music movement centred on New York City's Greenwich Village in the 1940s and '50s, with its strong association with leftist politics, but ultimately a role model for singer-songwriter Bob Dylan, who championed social protest in the early 1960s at the head of the folk music revival.

Woody Guthrie

In Hollywood, too, some of the leading directors of the 1930s, such as Capra in *Mr. Deeds Goes to Town* (1936) and *Mr. Smith Goes to Washington* (1939) or John Ford in his movie version of *The Grapes of Wrath* (1940), addressed the corruption of corporate and political power in modern America or the wretched conditions in which migrant farmers lived. The hollowed-out face of Henry Fonda as Steinbeck's Tom Joad, after all, was as potent an icon of the 1930s as Astaire's top hat and tails.

But few images from this period have lasted as long, or had as great an influence on filmmaking in America and abroad, as that of the fictional media mogul Charles Foster Kane in *Citizen Kane*. Directed by and starring a 25-year-old Welles and released in 1941, the movie was astonishing in part because of its stylistic virtuosity but also because it rebelled against the political clichés of the 1930s. By telling Kane's story from multiple perspectives, by presenting him as a man to be feared or pitied as well as occasionally admired, and by acknowledging at the end that no single word (not even "Rosebud") could explain a person's life, the movie refused to pass judgment or deliver a message—refused to say that this man of wealth and power is evil or that the society that produced him is in need of fundamental change. Neither sentimental nor propagandistic, *Citizen Kane* transcended the filmmaking conventions and the preconceptions of the 1930s and hinted at a more ironic age, with fewer certitudes, that would follow World War II.

PORTRAYALS OF HOPE

Americans in 1941, however, were not yet ready for the cool detachment of *Citizen Kane*. After 10 years of hard times, when the Depression felt like a natural as well as economic disaster (made worse by real environmental catastrophes such as floods and dust storms), what people wanted from their government and their popular culture was comfort. By the late 1930s, all but a few Americans longed not for revolution but for recovery, not for uncertainty but for stability, not for more social conflict but for a sense of national unity.

These essentially conservative impulses dominated the closing years of the Great Depression, though they had been present all along. Franklin D. Roosevelt recognized the craving for solace in the midst of chaos by clothing his reforms in conservative language. The very names of the New Deal agencies and programs—the National Recovery Administration, the Agricultural Adjustment Administration, the Civilian Conservation Corps, the Tennessee Valley Authority, Social Security—promised that America would be repaired and strengthened rather than transformed. Floods would be "controlled"; hydroelectric power would be "harnessed"; the soil would be "conserved"; order would be "restored." In short, Americans would get a new, fairer deal of the cards but not a brand-new game with perplexing new rules. Even African Americans—for many of whom the toils of the Great Depression were hardly different from the travails of everyday life in segregated America—found hope and inspiration in the New Deal, especially as it was enunciated by first lady Eleanor Roosevelt. They showed their support by switching their political allegiance from the Republican Party to the Democratic.

Conservative impulses

The Roosevelt administration's rhetoric and its policies were devised for a country that had shed the optimism and the innocence of the 1920s, a country that now regarded itself, psychologically, as middle-aged. The popular culture of the 1930s reinforced this perception that Americans had entered an era of limits, where they should make the best of what they already had rather than embarking on a quest for the unobtainable. The title of one of the decade's best-selling self-help books, *Life Begins at Forty* (1932) by Walter Pitkin, implied that a wise if chastened maturity was emotionally healthier and more realistic than adolescent self-confidence. At the same time, movies such as Capra's *It Happened One Night* (1934), *You Can't Take It with You* (1938), and *Meet John Doe* (1941) suggested that people were happier and better off if they were not rich and that the familiar pleasures of home and family were more fulfilling than the ambitions of the powerful or the affectations of the elite. This was a soothing idea for people whose dreams of a more affluent and adventurous life had vanished.

The conservatism of the 1930s coincided with a revival of interest in the American past and a veneration of America's legendary heroes. The publication of multivolume biographies of George Washington, Andrew Jackson, and Robert E. Lee, or epic poems like Archibald MacLeish's *The Land of the Free* (1938), reminded people of the leaders (whatever their differing philosophies) who had guided the nation through its earlier crises. This reverence for tradition, which encouraged Americans to believe they could prevail over their current predicaments, was the subtext of the decade's most famous novel and the movie that set box-office records both in the 1930s and for the next half century, *Gone with the Wind* (book, 1936; movie, 1939).

The resurgence of cultural nationalism was hardly unique to the United States. Britain, France, Germany, Italy, the Soviet Union, and Japan were all competing with one another in the glorification of their histories and their values through international automobile races, aviation speed and endurance contests, the acquisition of gold medals at the Olympic Games of 1932 and 1936, and shortwave overseas radio broadcasts such as the British Broadcasting Company's Empire Service. By the end of the 1930s, the Roosevelt administration—fearing the spreading influence of Germany and Italy through the growth, in Latin America, of large émigré populations from those two countries—had entered the culture war by establishing libraries, educational exchanges, and U.S. schools in Mexico, Brazil, Argentina, and Chile. These initiatives marked the beginning of the U.S. government's far more extensive strategy of exporting American culture as an instrument of foreign policy during World War II and the Cold War.

Resurgence of cultural nationalism

Even as the worst economic problems of the Great Depression began to lift, the prevailing mindset could not forget the lessons of the era. The trust in the federal government to solve or at least address the fundamental dilemmas of various groups in American society (the elderly with Social Security, blue-collar workers with the Na-

tional Labor Relations Act, poor Southern farmers with the Tennessee Valley Authority), the dependence on Washington as the ultimate supervisor of corporate behaviour, the thirst for social and psychological security, the need to hold a job and save money as protection against some future economic crisis—all of these predilections continued to shape the mentality of Americans who lived through the Great Depression even after America's victory in World War II and the return of prosperity. The emotional scars, the fear of fear itself, could never be eradicated.

But the Great Depression and its aftermath also encouraged a faith in, and a love of, what America presumably stood for. These were not the sort of feelings one might have expected in a decade in which many people were initially angry about the failure of America's economic and social arrangements. Yet the transition from rage to reconciliation was reflected, symbolically, in one of the decade's most cherished movies, *The Wizard of Oz* (1939). Here Dorothy (played by Judy Garland) is transported from her drab, gray Kansas farm to the magical and Technicolor land of Oz. She and her companions—a scarecrow, a tin woodsman, and a cowardly lion—each seeking to change themselves or their circumstances, go off to see the wizard "because of the wonderful things he does." Although the wizard turns out to be a charlatan, he has an important lesson to teach, not just to his supplicants but to audiences in the 1930s. People, he says, do not need a wizard and his miracles; all they need to do is look inside themselves. So a movie that begins with Dorothy imagining a fantasy world somewhere over the rainbow ends with her back in Kansas, proclaiming "There's no place like home."

And in the midst of World War II, as the economy recuperated and people went back to work, the virtues of life at home became more palpable to most Americans. In 1939 John Steinbeck had portrayed an Oklahoma in *The Grapes of Wrath* that, like the rest of America, was still marked by scarcity and deprivation. In 1943 Richard Rodgers and Oscar Hammerstein opened a new musical, called *Oklahoma!*, on Broadway. Their Oklahoma, unlike Steinbeck's Dust Bowl, was a bountiful land where the corn was as high "as an elephant's eye."

The musical, with its joyous evocation of beautiful mornings, summed up the spirit of a people who had finally freed themselves from the constraints of the 1930s and could once again relish the vitality of the United States. It was this America—having survived its idiosyncratic crisis in the 1930s and having escaped the bombing of its cities and the destruction of its natural resources during World War II—that the rest of the world would have to decipher and deal with in the postwar years. (R.H.Pe.)

BIBLIOGRAPHY

Economic history. MILTON FRIEDMAN and ANNA JACOBSON SCHWARTZ, *A Monetary History of the United States, 1867–1960* (1963, reissued 1993), chapter 7, "The Great Contraction," is the single most important study of the Great Depression in the United States, detailing ways in which banking panics and monetary contraction contributed to the economic downturn.

Scholarly studies that analyze the role of particular factors in the American Depression include BEN S. BERNANKE, "Nonmonetary Effects of the Financial Crisis in the Propagation of the Great Depression," *American Economic Review*, 73(3):257–276 (June 1983); STEPHEN G. CECCHETTI, "Prices During the Great Depression: Was the Deflation of 1930–1932 Really Unanticipated?," *American Economic Review* 82(1):141–156 (March 1992); CHRISTINA D. ROMER, "The Great Crash and the Onset of the Great Depression," *Quarterly Journal of Economics*, 105(3):597–624 (August 1990); and PETER TEMIN, *Did Monetary Forces Cause the Great Depression?* (1976). JOHN KENNETH GALBRAITH, *The Great Crash, 1929* (1954, reissued 1997), is a riveting account of the 1929 stock market crash, one of the events leading up to the Great Depression in the United States.

International economy: BARRY EICHENGREEN, *Golden Fetters: The Gold Standard and the Great Depression, 1919–1939* (1992, reissued 1995), is an important study of the functioning and effects of the international gold standard in the interwar era. W. ARTHUR LEWIS, *Economic Survey, 1919–1939* (1949, reissued 1969), while somewhat dated, is an exceedingly useful survey of the nature and causes of the Depression in Great Britain, Germany, Russia, France, Japan, and the United States. Other works analyzing the Depression outside the United States include HAROLD JAMES, *The German Slump: Politics and Economics, 1924–1936* (1986); CHARLES P. KINDLEBERGER, *The World in Depression, 1929–1939*, rev. and enlarged ed. (1986); and ROSEMARY THORP (ed.), *Latin America in the 1930s: The Role of the Periphery in World Crisis* (1984).

Recovery: LESTER V. CHANDLER, *America's Greatest Depression, 1929–1941* (1970), provides a detailed description of the many programs implemented to deal with the Depression in the United States. BARRY EICHENGREEN and JEFFREY SACHS, "Exchange Rates and Economic Recovery in the 1930s," *Journal of Economic History*, 45(4):925–946 (December 1985), discusses how devaluation and monetary expansion contributed to economic recovery from the Depression in many countries. Two studies that examine the role of policy in ending the American Depression are E. CARY BROWN, "Fiscal Policy in the 'Thirties: A Reappraisal," *American Economic Review*, 46(5):857–879 (December 1956); and CHRISTINA D. ROMER, "What Ended the Great Depression?," *Journal of Economic History*, 52(4):757–784 (December 1992).

Impact: MICHAEL D. BORDO, CLAUDIA GOLDIN, and EUGENE N. WHITE (eds.), *The Defining Moment: The Great Depression and the American Economy in the Twentieth Century* (1998), includes a series of papers by distinguished scholars on the long-run impact of the Great Depression in the United States. JOHN MAYNARD KEYNES, *The General Theory of Employment, Interest, and Money* (1936, reissued 1997), is the pathbreaking work of economic theory that was inspired by the Great Depression and led to the rise of stabilization policy in the postwar era. (C.D.Ro.)

Culture and society in the Great Depression. T.H. WATKINS, *The Hungry Years: A Narrative History of the Great Depression in America* (1999), is a comprehensive political and social history of the Great Depression in the United States; while PIERS BRENDON, *The Dark Valley: A Panorama of the 1930s* (2000), takes a more international approach, comparing the effects of the Depression in the United States, Britain, Germany, France, the Soviet Union, China, and Japan.

Other works that deal with cultural issues, both in the 1930s and in the 20th century, include RICHARD H. PELLS, *Radical Visions and American Dreams: Culture and Social Thought in the Depression Years* (1973, reprinted 1998); WARREN I. SUSMAN, *Culture as History: The Transformation of American Society in the Twentieth Century* (1973, reissued 2003); LAWRENCE W. LEVINE, *The Unpredictable Past: Explorations in American Cultural History* (1993); and MICHAEL KAMMEN, *American Culture, American Tastes: Social Change and the 20th Century* (1999). Chapter 1 of RICHARD H. PELLS, *Not Like Us: How Europeans Have Loved, Hated, and Transformed American Culture Since World War II* (1997), explores the role of American foundations in bringing refugee scholars, scientists, artists, and filmmakers to the United States in the 1930s, and it discusses the Roosevelt administration's efforts to export U.S. culture to Latin America at the end of the decade.

Two memoirs are still useful in illuminating the cultural and intellectual preoccupations of the 1930s: HAROLD CLURMAN, *The Fervent Years: The Story of the Group Theatre and the Thirties* (1945, reprinted 1983), is a personal history of the Group Theatre by one of its founders; and ALFRED KAZIN, *Starting Out in the Thirties* (1965, reprinted 1989), describes the polemical battles on the left and explores American reactions to the announcement of the Nazi-Soviet Pact in 1939. MARIA DIBATTISTA, *Fast-Talking Dames* (2001, reissued 2003), is excellent on the movies of the 1930s and on the actresses who delivered the witty dialogue that was Hollywood's trademark during these years. (R.H.Pe.)

Diagnosis and Therapeutics

Diagnosis, from the Greek *gnosis* meaning knowledge, is the art of determining the nature of a disease and distinguishing one disease from another. The diagnostic process is the method by which health professionals identify one disease rather than another as the most likely cause of a person's symptoms. Symptoms that appear early in the course of a disease are often more vague and undifferentiated than those that arise as the disease progresses, making the early stages the most difficult time to make an accurate diagnosis. Reaching an accurate conclusion depends on the timing and the sequence of the symptoms, past medical history and risk factors for certain diseases, and a recent exposure to disease. The physician, in making a diagnosis, also relies on various other clues such as physical signs, nonverbal signals of distress, and the results of selected laboratory and radiological tests. From the large number of facts obtained, a list of possible diagnoses can be determined, which are referred to as the differential diagnosis. The physician organizes the list with the most likely diagnosis given first. Additional information is identified, and appropriate tests are selected that will narrow the list or confirm one of the possible diseases.

Therapeutics is the art and science of treating disease. It comes from the Greek *therapeutikos,* which means "inclined to serve." In a broad sense therapeutics means serving and caring for the patient in a comprehensive manner, preventing disease as well as managing specific problems. Exercise, diet, and mental factors are therefore integral to the prevention as well as the management of disease processes. More specific measures that are employed to treat specific symptoms include the use of drugs to relieve pain or treat infection, surgery to remove diseased tissue or replace poorly functioning or nonfunctioning organs with fully operating ones, and counseling or psychotherapy to relieve emotional distress caused by the illness or its treatment. Confidence in the physician and in the method selected enhances effectiveness.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* Part Four, Division II, especially sections 423 and 424.

This article is divided into the following sections:

DIAGNOSIS

Historical aspects

Traditionally, diagnosis has been defined as the art of identifying a disease from its signs and symptoms. Formerly, few diagnostic tests were available to assist the physician, who depended on medical history, observation, and examination. Only recently, with the many technological advances in medicine, have tests become available to assist in making specific diagnoses.

The Greeks

Medicine and personal hygiene reached new heights in the 5th century BC at the time of the Greek physician, Hippocrates. The Greeks recognized the salubrious effects of bathing, fresh air, a good diet, and exercise, which have received renewed attention today. Illness was thought to result from an imbalance between the four humours of the body: blood, phlegm, yellow bile, and black bile. The Greeks emphasized the value of observation, including bodily signs and excretions. The focus, however, was more on predicting the outcome of an illness (*i.e.,* prognosis) and less on its diagnosis. A physician's reputation depended on accurate prognostic skills, predicting who would recover and who would die or how long an illness would last.

Hippocrates is credited with establishing the ethical basis of the physician's behaviour, and graduating physicians still recite the oath ascribed to him. His writings document the value of objectively evaluating all aspects of the patient's symptoms, diet, sleep patterns, and habits. No finding was considered insignificant, and physicians were encouraged to employ all their senses—sight, hearing, smell, taste, and touch—in making a diagnosis. These principles hold just as true today.

The Romans made significant advances in supplying and purifying water and in improving sanitation.

Galen (AD 130–200) is considered the most influential physician after Hippocrates because of his extensive studies in anatomy and physiology. His voluminous writings in anatomy and physiology rendered him the ultimate authority in these fields until the 16th century. As the first

experimental neurologist, he described the cranial nerves and the sympathetic nervous system. He showed that the heart will continue beating when removed from the body and thus does not depend on the nervous system. Many of his views, however, contained fallacies, which remained unchallenged for centuries. His description of the heart and its chambers and valves, in which he contended that blood passes from the right to the left ventricle by means of invisible pores in the interventricular septum, delayed the discovery of blood circulation for 14 centuries. The true nature of the circulation of blood was not recognized until the time of William Harvey (1578–1657), who published his findings in *Exercitatio anatomica de motu cordis et sanguinis in animalibus* (translated as *An Anatomical Dissertation Upon the Movement of the Heart and Blood in Animals* and usually referred to as *De Motu Cordis*).

From the Middle Ages to the 18th century, uroscopy (examination of the urine) was a common method for diagnosing illness. The colour of the urine, as well as cloudiness, precipitates, and particles in the urine, was believed to indicate the cause of the disorder.

Diagnostic tools

One of the greatest advances in diagnostic tools was the invention of the compound microscope toward the end of the 16th century by the Dutch spectacle makers Hans Jansen and his son Zacharias. In the early 17th century Galileo constructed a microscope and a telescope. One of the great early microscopists, Antonie van Leeuwenhoek (1632–1723), was the first to see protozoa and bacteria and the first to describe red blood cells. He also demonstrated the capillary anastomosis (network) between arteries and veins that proved Harvey to be correct.

Although the mercury thermometer of Daniel Fahrenheit (1686–1736) appeared about 1714, it was not until 1866 that it came into general use as a clinical tool. It was initially 25.4 centimetres (10 inches) long and took five minutes to register a temperature. A pocket version was developed by Sir Thomas Clifford Allbutt in 1866. The thermometer was popularized by Karl August Wunderlich who thought, incorrectly, that every disease had its own characteristic fever pattern.

Another significant medical advance, which greatly improved the ability to diagnose diseases of the chest and heart, was the invention of the stethoscope in 1816 by René-Théophile-Hyacinthe Laënnec (1781–1826). Before this, the lungs and heart were examined by applying the ear to the chest wall. Laënnec initially used a roll of papers to enhance sounds from the chest and later replaced this "instrument" with a wooden cylinder. He improved the original monaural (one-ear) stethoscope with the binaural device still in current use. Tuberculosis was prominent at the time, and the stethoscope allowed Laënnec to diagnose this condition at an earlier stage than was previously possible.

Another significant diagnostic aid was the ophthalmoscope developed by Hermann von Helmholtz (1821–94), a physician best known for his knowledge of physics and mathematics. With this device, the retina and blood vessels could be seen through the pupil, allowing the inner eye to provide information not only concerning diseases of the eye but also about those pertaining to cardiovascular abnormalities and complications of diabetes mellitus.

Perhaps the greatest modern anatomic diagnostic tool is the X ray, discovered in 1895 by the German physicist Wilhelm Conrad Röntgen. X rays have since been commonly referred to as roentgen rays, and their application eventually led to the development of computerized tomography and magnetic resonance imaging, two techniques that are extremely useful modern diagnostic tools.

Medical training

The training of physicians also has undergone significant change over the years. Until the end of the 19th century, physicians were trained through lectures and rarely were taught at the patient's bedside. This practice was altered by Sir William Osler, one of the most renowned physicians of the early 20th century, who introduced the practice of instructing students at the bedside of the patient. He emphasized the importance of taking an accurate medical history, providing a thorough examination of a patient, and closely observing the patient's behaviour to gather clues for a diagnosis before resorting to laboratory testing.

Medical history

The medical history of a patient is the most useful and important element in making an accurate diagnosis, much more valuable than either physical examinations or diagnostic tests. The medical interview is the process of gathering data that will lead to an understanding of the disease and the underlying physiological process. To be effective, an interviewer must possess good communication skills and be alert to nonverbal clues as well as to the verbal message. Often, more information is conveyed by nonverbal actions and tone of voice than by words. The objective is to obtain an accurate and comprehensive picture of the patient's situation, including the nature and timing of symptoms, emotional factors (including types of stress), and past medical conditions that may place the patient at greater risk for certain diseases.

The medical interview

The accuracy and usefulness of the medical interview depend on the physician's ability to elicit information pertinent to the problem at hand and on the patient's accurate recall and articulation of the sequence of symptoms. This may be difficult because meaningful data may be forgotten if the patient is experiencing pain or emotional distress. The skilled interviewer knows when to use silence, open-ended questions, or specific closed-ended questions to explore avenues in which the most useful information may be found. The real reason for the patient's visit may not be apparent until a rapport has been established and the person feels comfortable describing what is most bothersome. Problems that are emotionally threatening may not be voiced until adequate courage is summoned—sometimes not until the end of the appointment when the patient's hand is on the doorknob.

A complete medical history consists of an account of the present illness, the past medical history, family history, occupational background, psychosocial history, and a review of body systems.

An account of the present illness, which includes the circumstances surrounding the onset of recent health changes and the chronology of subsequent events that have led the patient to seek medical care, is essential to understanding the course of the disease process. Current medications are listed in the medical history because they may play a role in the current illness.

The past medical history is an overall view of the patient's health prior to the present illness. It should include previous hospitalizations, injuries, operations, and any significant illness that may not have required hospitalization. Allergies are included here if not listed separately.

Family history

Included in a family history are the age and state of health of each immediate family member as well as the cause of death of any parents, grandparents, and other close relatives. Of particular importance are genetic or environmental diseases that have known risks. If a close relative such as a father died of a heart attack (acute myocardial infarction) before the age of 60, all his children are at greater risk of suffering an early heart attack. This risk increases if other factors such as hypertension (high blood pressure) or elevated serum cholesterol are present. Similarly, a history of some cancers (*e.g.*, colon cancer) increases the risk for offspring to develop that type of cancer. The development of lung cancer in a parent provides even greater impetus for close relatives to avoid smoking. Other diseases that may have hereditary or environmental roots are diabetes, hypertension, tuberculosis, depression and other forms of mental illness, arthritis, and epilepsy. Actually, any disease that arises in two or more members of a family suggests a possible predisposing factor, and the patient should be considered to be at increased risk for this condition.

The occupational history is important because the workplace may be a source of toxins, such as chemicals or cigarette smoke, that place one at higher risk of cancer or other diseases.

The psychosocial history—information on education, lifestyle, marital status, and religious beliefs—may influence future medical decisions, as may the patient's smoking history, alcohol intake, and use of such controlled substances as marijuana or cocaine.

The review of body systems allows the physician to identify any other symptoms that have not been noted previously and that may influence the patient's current state of health or provide subtle clues to the diagnosis. All major body systems are reviewed in an orderly manner, usually from the head down to the extremities. The intent is to uncover any past illnesses or problems that have not been previously identified and that may now or later influence the patient's health. For example, the patient may describe leg pain while walking, which could be an early indication of blood vessel occlusion and increase the physician's concern about possible coronary artery disease that otherwise may not have been suspected.

Physical examination

MANUAL PROCEDURES

The physical examination continues the diagnostic process, adding information obtained by inspection, palpation, percussion, and auscultation (see below). When data accumulated from the history and physical examination are complete, a working diagnosis is established, and tests are selected that will help to retain or exclude that diagnosis.

Patients are usually apprehensive and anxious when being examined because they feel exposed, vulnerable, and afraid of discomfort. The physician attempts to allay that anxiety by explaining which examinations are to be performed and the degree of discomfort that will be entailed. Throughout the examination, concern for the patient's dignity must be maintained.

Inspection. A wide array of sophisticated instruments is available to assist with examinations, but a well-performed visual inspection can often reveal more information. Osler admonished physicians to closely observe patients before touching them, to cultivate the power of observation, as it is one of the greatest diagnostic tools. Wasting and hallmarks of poor nutrition may indicate chronic disease; poor grooming or slack posture may suggest depression or low self-esteem.

Visual inspection

Inspection begins with the patient's general appearance, state of nutrition, symmetry, and posture. The physician then proceeds to more specific examination of the skin—looking for redness or other signs of infection, hair loss, nail thickening, and moles or other areas of pigmentation—and inquires about any recent changes in skin lesions that could indicate early cancer.

Examination of the nails can provide important clues about systemic disease. Clubbing of the nails (broadening of the nailbeds, with curved and shiny nails) may indicate congenital heart disease, chronic obstructive pulmonary disease, bronchogenic carcinoma, or another cardiac or pulmonary condition. Pitting of the nails occurs in about 50 percent of patients with psoriasis.

Inspection should encompass, in particular, areas that the patient normally would not be able to see, such as the scalp, back, and buttocks.

The skin should always be inspected for cancer, though it is sometimes difficult to differentiate a benign mole (nevus) from a cancer. The most dangerous skin cancer, malignant melanoma, occurs in about 1 in 10,000 people and can spread readily throughout the body. A squamous-cell carcinoma also may spread but is slow to do so and can be completely cured by early detection and removal. Basal-cell cancer is the most common form of skin cancer, and, though it is locally invasive, it does not spread. Suspicious lesions are those that have recently enlarged, started to bleed, become darker, or developed an irregular outline. Most skin cancers occur on areas of the body that have been exposed to the sun; they are more common in light-skinned individuals with blond hair and blue eyes who sunburn easily.

The most common premalignant (precancerous) skin lesion is actinic keratosis, a rough, scaling, red or brown papule that appears on sun-exposed areas such as a bald scalp, ears, the forehead, and the back of the hands. These lesions can be easily removed by cryotherapy (therapeutic use of cold) or electrodesiccation (dehydration of tissue by electric current).

Palpation. Palpation is the act of feeling the surface of the body with the hands to determine the characteristics of the organs beneath the surface. It can be performed with one hand or two and can be light or deep.

Types of palpation

Light palpation is used to detect tenderness, muscle spasm, or rigidity of the abdomen. If abdominal pain is present, gentle palpation begins farthest away from the pain to localize the point of maximum tenderness. Acute inflammation in the abdomen, as in acute appendicitis, causes peritoneal irritation, resulting in not only localized tenderness in the right lower abdomen but also a guarding reaction (tightening and rigidity) by the muscles in that area to protect the inflamed organ from the external pressure.

Deep palpation of the abdomen is used to determine the size of the liver, spleen, or kidneys and to detect an abnormal mass. An abdominal aortic aneurysm can be detected by palpating a pulsatile mass in the upper abdomen. An acutely tender mass in the right upper abdomen that is more painful on inspiration is probably an inflamed gallbladder. An unexplained nontender abdominal mass could be as nonthreatening as a hard stool or as serious as a tumour.

Palpation also is used to detect and evaluate abnormal lesions in the breast, prostate, lymph nodes, or testicles. Proper breast examination includes frequent (at least monthly) self-examinations and an annual examination by a physician. Palpation should be methodical and performed over the entire breast; the method of action is done either in concentric circles or outward from the nipple using a spokes-of-a-wheel approach. Suspicious breast lesions are hard and fixed rather than movable. Skin retraction or breast asymmetry can indicate an underlying, potentially serious lesion. Cancers are usually not tender, and benign lesions are more likely to be round, elastic or firm, movable, and well-defined. Similarly, suspicious prostate lesions are hard, irregular nodules within the prostate, whereas benign prostatic hyperplasia (BPH) is a soft symmetrical enlargement of the gland.

Palpation also can detect cardiac enlargement if the point of maximal impulse (PMI) of the heart is farther left than normal. Other cardiac abnormalities can be suspected if a thrill is felt using light palpation over the chest wall. A thrill is a vibratory sensation felt on the skin overlying an area of turbulence and indicates a loud heart murmur usually caused by an incompetent heart valve.

Percussion. Percussion is a diagnostic procedure used to determine the density of a part by tapping the surface with short, sharp blows and evaluating the resulting sounds. In the abdomen it can be used to detect fluid (ascites), a gaseous distention of the intestine as occurs in bowel obstruction, or an enlargement of the liver. It is used most often to evaluate the chest. Percussion produces a resonant note when the area over a healthy lung is struck; a dull sound, however, will emanate if the lung contains fluid, as in pneumonia, or when a region over a solid mass such as the heart is tapped. A lung that is diseased with emphysema contains more air than a healthy lung and produces hyperresonance. A stomach distended with air will produce a high-pitched, hollow tympanic sound.

Auscultation. Auscultation is performed with a stethoscope to evaluate sounds produced by the heart, lungs, blood vessels, or bowels. The lack of bowel sounds indicates a nonfunctioning or paralyzed bowel, and high-pitched "tinkling" bowel sounds suggest bowel obstruction. The "growling" of the stomach is an accentuation of these sounds during periods of bowel hyperactivity.

Body sounds provide diagnostic clues

Bruits are blowing vascular sounds resembling heart murmurs that are perceived over partially occluded blood vessels. When detected over the carotid arteries, a bruit may indicate an increased risk of stroke; when produced by the abdomen, it may indicate partial obstruction of the aorta or other major arteries such as the renal, iliac, or femoral arteries.

Listening to the sound of air passing in and out of the lungs can be useful in detecting an obstruction as in asthma or an inflammation as in bronchitis or pneumonia. Adventitious sounds are those heard in addition to normal breathing sounds and include crackles, wheezes, and rubs. Crackles (also called rales) resemble the sound

made by rubbing hair between the fingers next to the ear. They are caused by fluid in the small passageways that adheres to the walls during respiration. Crackles are heard in congestive heart failure and pneumonia. Wheezes, musical sounds heard mostly during expiration, are caused by rapid airflow through a partially obstructed airway as in asthma or bronchitis. Pleural rubs sound like creaking leather and are caused by pleural surfaces roughened by inflammation moving against each other, which occurs in patients with pneumonia and pulmonary infarction.

Cardiac auscultation is the evaluation of the sounds made by the heart valves—namely, the aortic, pulmonary, tricuspid, and mitral—for murmurs that may be due to turbulent blood flow or vibrations from a heart valve deformity. Murmurs may be physiological (unimportant clinically) or pathological, indicating a problem that needs attention, especially if they reflect obstruction of normal blood flow. Heart murmurs vary according to their timing in the cardiac cycle (systole, the period of contraction when blood is pumped from the heart, and diastole, the period of heart expansion between pumping), location, duration, intensity, pitch, and quality. Intensity is graded on a scale from 1 to 6, with 6 being the loudest. Heart murmurs are described as "grade 2/6"—the numerator represents the intensity of the murmur, and the denominator indicates the highest grade of the scale being used. However, the intensity of the murmur alone provides little information about the clinical severity of the problem. An ejection murmur caused by turbulence across the aortic valve during systole can be either serious or nonthreatening depending on its cause, even though the intensity of the murmur may be the same. Therefore, the pitch and quality of the murmur also are described. Pitch is usually reported as high or low, and quality is described as harsh, soft, blowing, musical, or rumbling. For example, the murmur of mitral stenosis may be described as a grade 3/6, low-pitched, rumbling, presystolic murmur heard best at the apex and having an increased first heart sound at the apex.

SPECIAL EXAMINATIONS

Evaluation of body systems

Emergency. Of greatest importance in an emergency is the evaluation of systems that are essential to sustaining life—namely, the circulatory, respiratory, and central nervous systems.

First, the person in distress should be checked to determine whether breathing is normal or at least whether there is adequate exchange of air to ensure oxygenation of the blood. If the person is unconscious, the first maneuver is to tilt the head back and lift the chin (unless a neck injury is suspected) to prevent the tongue and jaw from obstructing the airway and then to provide artificial respiration. If the person has eaten recently, the cause may be obstruction by a foreign body (usually food), and the Heimlich maneuver (subdiaphragmatic abdominal thrust) should be performed.

Second, the circulation should be evaluated. Is the heart beating, and is the output adequate to provide oxygenated blood to the tissues, or has this been compromised by excessive bleeding? A blood pressure greater than 100/60 millimetres of mercury (mm Hg) indicates adequate perfusion.

Shock occurs when the blood pressure falls to extremely low levels because of inadequate blood volume (hypovolemic shock), poor heart function (cardiogenic shock), or malfunction of the vascular system that results in lost peripheral vascular tone, vasodilation, and pooling of the blood (neurogenic shock). Signs of shock are a rapid and weak pulse, pale complexion, sweating, and confusion. Organs particularly sensitive to injury if the shock is not corrected are the brain, heart, lungs, kidneys, and liver.

Examination of the unconscious patient

An unconscious person may not respond to external stimulation, in which case the person would be in a coma, or the patient may exhibit varying levels of unconsciousness, responding only to painful stimuli (deep level of unconsciousness) or when shaken or called by name (light level). Pupil size and reactivity to light can provide clues to the status of the nervous system. Bilateral dilated pupils that do not contract when a light is placed on one of them indicate death or severe damage to the nervous system. Small pupils that do react to light are seen in narcotic overdose. If one pupil is larger than the other, a brain lesion on one side or hemorrhage should be suspected.

Pediatric. Examinations to assess the well-being of children begin at birth. The Apgar score, named for the anesthesiologist Virginia Apgar, is obtained at one and five minutes after birth and indicates the condition of the newborn. A score of 0 (absent), 1, and 2 is given for each of the five parameters, which are heart rate, respiratory effort, muscle tone, reflex irritability, and colour. Infants scoring between 7 and 10 at one minute will likely do well with no special treatment; those scoring between 4 and 6 may require stimulation or brief respiratory support; those scoring 3 or below will probably need extended resuscitative efforts. Infants who have a score of 7 or above at five minutes will continue to do well. The Apgar score is usually reported as two numbers, from 1 to 10, that are separated by a virgule, the first number being the score at one minute, the second the score at five minutes.

Developmental assessment is measured with growth charts developed by the National Center for Health Statistics. A child's length (or height) and weight are plotted over time on standard graphs constructed from data gathered from a large number of average-sized children. The average length of a newborn infant is 50 centimetres (20 inches). The length increases by 50 percent at 12 months of age and doubles to 100 centimetres when the child is 4 years old. The average weight at birth is 3.4 kilograms (7.5 pounds), which doubles in 4 to 5 months and triples when the child is 12 months old. After 2 years of age, height increases by 5 centimetres and weight increases by 2.3 kilograms per year until the growth spurt during adolescence.

Psychosocial development can be measured using the Denver Developmental Screening Test. This test evaluates motor, language, and social development skills in children up to 6 years of age.

Adolescent growth

The adolescent growth spurt is closely associated with the development of the reproductive system. Puberty occurs in American girls starting at 10 or 11 years of age (average) and in American boys at age 11. In girls the first sign of puberty is the breast bud followed by breast and pubic hair development. In boys it is growth of the testes with reddening and wrinkling of the scrotum. Pubic hair appears within six months of these first signs of puberty, followed in another six months or so by enlargement of the penis.

Hearing is evaluated early, and a disorder should be suspected if speech is delayed or abnormal. Vision testing is begun in the newborn to detect strabismus and other congenital abnormalities. Visual acuity can be evaluated in children 2 to 3 years of age. Dental appointments should begin when the child is 2 or 3, because the eruption of primary teeth is usually complete by 2 years of age. Permanent teeth begin erupting about age 6 and are all in place by age 12 or 13 years.

Geriatric. The number of people in the United States older than 65 years of age is increasing rapidly, and demographers project that soon 50 percent of the American population will live to 85 years or older. As the body ages there is a steady loss in organ reserve (ability to function beyond the level normally required, which may be called upon in an emergency), which leads to decreasing functional capacity and increasing vulnerability to disease and disability. Age-related changes include the following:

1. Cellular changes occur, including decreased function and number.
2. Increased collagen results in greater stiffness and decreased tissue elasticity.
3. Muscle mass decreases, as does the mass of the liver, brain, and kidneys.
4. Cardiac output is reduced, the ability to respond to stress diminishes, and blood flow to the kidneys and other organs decreases.
5. Pulmonary function decreases because the number of alveoli lessens, expiratory muscles weaken, and there is a reduction in elastic recoil.
6. Gastrointestinal changes occur, including decreased secretion of stomach acid; decreased intestinal motil-

ity, resulting in constipation and dehydration of the stools; slower metabolism of drugs by the liver; increased incidence of gallstones; and loss of teeth, impairing proper chewing and digestion. Diverticulosis occurs in more than 50 percent of persons by age 80.

7. Excretory function diminishes because of a decrease in kidney mass and in the number of functioning nephrons.
8. Endocrine changes are noted and can include decreased functioning of thyroid and adrenal glands and decreased insulin production by the pancreas along with increasing insulin resistance that results in diabetes mellitus.
9. Neurological changes occur, including a slowing of nerve conduction velocity, a loss of brain substance, a reduction in the amount of deep sleep and an increase in the number of brief arousals, and a decrease in cerebral blood flow.
10. Visual acuity, hearing, taste, and smell decline. Vision is much more limited in dim light. The incidence of glaucoma and cataracts increases.
11. Height decreases because of the narrowing of the intervertebral disks and narrowing of the vertebrae, resulting in the loss of five centimetres by the age of 70 years.

Osteoporosis, which is demineralization of bone and loss of bone mass, results in an increased risk of fracture, especially of the hip, wrist, and spine. Bone loss is accelerated in women during menopause but can be prevented by administration of estrogen and calcium. Progesterone is added to prevent endometrial cancer if the uterus is still present.

Cancers occur most frequently in the elderly. Carcinoma of the colon is predominantly a disease of the geriatric population and is the second leading cause of death from cancer in the United States.

Depression and other mood disorders are more common among older individuals than among younger persons. The symptoms of depression may be more vague and are more likely to occur as physical symptoms than in other age groups.

Dementia (loss of intellectual function) is common among the elderly, and Alzheimer's disease is thought to account for more than 60 percent of these cases. Alzheimer's disease is characterized by a slowly progressive cognitive decline, in the absence of other causes of dementia. It affects about 10 percent of all persons older than 65 years of age.

Tests and diagnostic procedures

CLINICAL LABORATORY TESTS

Laboratory tests can be valuable aids in making a diagnosis, but, as screening tools for detecting hidden disease in asymptomatic individuals, their usefulness is limited.

Sensitivity and specificity of tests

The value of a test as a diagnostic aid depends on its sensitivity and specificity. Sensitivity is the measure of the percentage of individuals with the disease who have a positive test result (*i.e.,* people with the disease who are correctly identified by the procedure), and specificity is the measure of the percentage of people without the disease who have a negative test result (*i.e.,* healthy individuals correctly identified as free of the disease). If a test is 100 percent sensitive and the test result is negative, it can be said with certainty that the person does not have the disease, because there will be no false-negative results. If the test is not specific enough, however, it will yield a large number of false-positive results (positive test results for those who do not have the disease). The ideal test would be 100 percent sensitive and 100 percent specific; an example would be an early pregnancy test that was so accurate that it was positive in every woman who was pregnant and was never positive in a woman who was not pregnant. Unfortunately no such test exists. The normal value for a test is based on 95 percent of the population tested being free of disease, meaning that 1 out of every 20 test results in healthy individuals will be outside the normal range and therefore positive for the disease.

In the past, physicians would order selected tests based on the likelihood that the person had a certain disease. With the advent of automated analyzers, an increasing number and variety of tests have been made available at greatly reduced cost so that as many as 18 or more tests can be performed for what it previously cost to carry out three or four individual tests. A panel of chemical tests for blood and urine have become routine components of the basic medical workup. A disadvantage of this strategy is that each test produces some false-positive results and requires additional tests to rule out these diseases. The trend is reversing to perform only those tests most likely to be cost-effective.

A normal laboratory value is one that falls within a range that represents most healthy individuals. It is clear, however, that some healthy persons will have values outside that range and some individuals with disease will have values within the normal range. Thus, no sharp line divides normal and abnormal values. Tables of normal reference values must be updated regularly to react to changes in laboratory technique. Many normal values vary dramatically with age and gender.

SI units

Worldwide, the standard for reporting laboratory measurements is the International System of Units (SI units). The United States is the only major industrialized country that has not adopted the International System and continues to use customary units of measurement. Most tables provide both units to facilitate communication and understanding.

Body fluid tests. *Blood.* Blood is composed of plasma and blood cells. The blood cells—erythrocytes (red blood cells), leukocytes (white blood cells), and thrombocytes (platelets)—are suspended in the plasma with other particulate matter. Plasma is a clear, yellowish fluid that makes up more than half the volume of blood. It is distinguished from serum, which is the clear, cell-free fluid from which fibrinogen has been removed. Tests to measure the concentration of substances in the blood may use plasma, serum, or whole blood that has been anticoagulated to keep all the contents in suspension.

Complete blood count

A complete blood count (CBC) is a measure of the hematologic parameters of the blood (see the table for reference values). Included in the CBC is the calculation of the number of red blood cells (red blood cell count) or white blood cells (white blood cell count) in a cubic millimetre (mm^3) of blood, a differential white blood cell count, a hemoglobin assay, a hematocrit, calculations of red cell volume, and a platelet count.

The differential white blood cell count includes measurements of the different types of white blood cells that constitute the total white blood cell count: the band neutrophils, segmented neutrophils, lymphocytes, monocytes, eosinophils, and basophils. A specific infection can be suspected based on the type of leukocyte that has an abnor-

Reference Values in Hematology*

component	SI units	conventional units
Red blood cell count		
Female	$4.2–5.4 \times 10^{12}$/l	$4.2–5.4 \times 10^{6}/mm^3$
Male	$4.6–6.2 \times 10^{12}$/l	$4.6–6.2 \times 10^{6}/mm^3$
White blood cell count	$4.5–11.0 \times 10^{9}$/l	$4,500–11,000/mm^3$
Differential white blood cell count		
Band neutrophils	$150–400/mm^3$	3%–5%
Segmented neutrophils	$3,000–5,800/mm^3$	54%–62%
Lymphocytes	$1,500–3,000/mm^3$	25%–33%
Monocytes	$300–500/mm^3$	3%–7%
Eosinophils	$50–250/mm^3$	1%–3%
Basophils	$15–50/mm^3$	0%–1%
Hemoglobin		
Female	120–160 g/l	12.0–16.0 g/dl
Male	130–180 g/l	13.0–18.0 g/dl
Hematocrit		
Female	0.37–0.47	37%–47%
Male	0.40–0.54	40%–54%
Mean corpuscular volume	80–96 femtolitres	80–96 μm^3
Reticulocyte count	$25–75 \times 10^{9}$/l	$25,000–75,000/mm^3$
Platelet count	$150–350 \times 10^{9}$/l	$150–350 \times 10^{3}/mm^3$
Prothrombin time	12–14 seconds	12–14 seconds
Partial thromboplastin time	20–35 seconds	20–35 seconds
Plasma fibrinogen	2.0–4.0 g/l	200–400 mg/dl
Erythrocyte sedimentation rate		
Female	0–20 mm/h	0–20 mm/h
Male	0–15 mm/h	0–15 mm/h

*All values given for adults.

mal value. Viral infections usually affect the lymphocyte count, whereas bacterial infections increase the percentage of band neutrophils. Eosinophils are increased in those with allergic conditions and parasitic infection. Infection with the human immunodeficiency virus (HIV), which causes acquired immunodeficiency syndrome (AIDS), damages the body's ability to fight infection. The immune system of a healthy individual responds to infection by increasing the number of white blood cells, while the immune system of a person infected with HIV is unable to mount a defense of white blood cells (namely, lymphocytes) and cannot defend the body against viral or bacterial assault.

Of the calculations of red cell volume, the mean corpuscular volume (MCV) is the most useful for indicating anemia. The reticulocyte count, which measures the number of young red blood cells being produced, is used to distinguish between anemias resulting from a decrease in production of erythrocytes and those caused by an increase in destruction or loss of erythrocytes. An increase in the number of red blood cells (polycythemia) is normal for persons living at high altitudes, but in most of the population it indicates disease.

Platelets, small structures that are two to four micrometres in diameter, play a role in blood clotting. A decrease in the platelet count can result in bleeding if the number falls to a value below 50×10^3 per cubic millimetre.

Hematopoiesis (the production of blood cells) occurs in the bone marrow, and many types of blood disorders can be diagnosed best by analyzing a sample of bone marrow removed by a needle from the centre of the pelvic bone or the sternum (bone marrow biopsy).

Bleeding disorders are suspected when blood is seen in the skin (purpura) or a wound is delayed in clotting. In addition to a low platelet count in the peripheral blood, there may be a decrease in megakaryocytes, cells in the bone marrow that form platelets. A bleeding time greater than 20 minutes indicates an abnormality of platelet function. Other screening tests for coagulation disorders include the prothrombin time (PT) test, the partial thromboplastin time (PTT) test, and the plasma fibrinogen assay (see the table). Blood factors, which are protein elements essential to the clotting of blood, should be assayed if a disorder associated with one of them is suspected. For example, factor VIII or IX can be assayed if the patient is thought to have hemophilia.

The erythrocyte sedimentation rate (ESR) is the rate at which red blood cells settle in a column of blood in one hour. It is a nonspecific indicator of inflammatory disease that is also increased in anemia (see the table).

The Coombs, or antiglobulin, test (AGT) is used to test blood cells for compatibility when doing a cross match to detect antibodies that would interfere with a blood transfusion. It also is used to detect antibodies to red blood cells in hemolytic disease of the newborn and drug-induced hemolytic anemias.

Urine. Examining the urine is one of the oldest forms of diagnostic testing, extending back to the days of Hippocrates. Physicians observed the urine (uroscopy) to diagnose all forms of illness because direct examination of a patient, or at least disrobing the patient, was socially unacceptable (see above *Historical aspects*).

Urinalysis

Urinalysis is the most commonly performed test in the physician's office. It consists of (1) a gross examination, in which the colour, turbidity, and specific gravity of the urine are assessed, (2) the use of a dipstick (a plastic strip containing reagent pads) to test for bilirubin, blood, glucose, ketones, leukocyte esterase, nitrite, pH, protein, and urobilinogen, and (3) a microscopic examination of a centrifuged specimen to detect red or white blood cells, casts, crystals, and bacteria. The urine is collected using a "clean-catch" technique to eliminate contamination with bacteria from skin or vaginal secretions.

Dipstick tests are available that contain from 2 to 10 different tests. The test for glucose, which indicates diabetes, and the test for protein, which indicates kidney disease, tumours of the urinary tract, or hypertensive disorders of pregnancy, are two of the most important assays available.

The microscopic examination is the most valuable urinalysis test. It will show a variety of cells that are normally shed from the urinary tract. Usually up to five white blood cells per high-power field (HPF) are present; more than 10 white blood cells per HPF indicates a urinary tract infection. More than two red blood cells per HPF is abnormal, although in women this is often due to vaginal contamination from menstruation. Cylindrically shaped urinary casts, shed from the kidney's tubules, consist of protein mixed with cells or other materials and may indicate renal disease if present in large numbers. Various crystals also are found in the urinary sediment, but these are generally of little clinical significance.

Feces. The tests most commonly performed on feces are the fecal occult blood test (FOBT), stool cultures, and the examination for parasites. The fecal occult blood test is a low-cost method for detecting bleeding, which may be the first sign of carcinoma of the colon or rectum. Although the false-positive rate for this test is low, the false-negative rate is high. It is more likely to detect lesions in the right (ascending) colon because they bleed more than those in the left (descending) colon. Routine surveillance for colorectal cancer depends on periodic fecal occult blood testing combined with direct visualization of the lower colon with a sigmoidoscope (see below).

Fecal occult blood test

Individuals who are at increased risk for colon cancer and should be screened regularly are identified by any of the following criteria: age greater than 50 years, previous colorectal cancer or adenoma, family history of colon cancer or polyps in a first-degree relative or another genetic predisposition (*e.g.*, cancer family syndrome), history of ulcerative colitis or Crohn's disease, or personal or family history of genital or breast cancer.

Stool cultures are obtained when diarrhea is severe and particular bacteria such as *Salmonella, Shigella,* or *Giardia* are suspected. If a parasitic infection is suspected, the stool is examined under the microscope for the eggs or cysts of parasites such as pinworms (*Enterobius vermicularis*) or roundworms (*Ascaris lumbricoides*).

Cerebrospinal fluid. Examination of the cerebrospinal fluid, obtained by lumbar puncture (*i.e.*, a needle inserted into the lower back), is performed if meningitis or hemorrhage into the central nervous system (subarachnoid hemorrhage) is suspected. The fluid is normally crystal clear and colourless. It will contain blood if subarachnoid hemorrhage has occurred.

Tests give clues to various disease processes. Viral meningitis can be differentiated from bacterial meningitis by the type of white blood cells identified, although a bacterial culture is the definitive test. The glucose value will usually be normal in patients with viral meningitis but low in those with bacterial and fungal meningitis. The protein level is increased in individuals with meningitis and tumour. The pressure of the fluid within the spinal canal is measured after the needle is inserted. The pressure is elevated in the presence of infection and tumour.

Gastric fluid. By passing a tube through the nose and into the stomach, gastric fluid can be obtained from the stomach for examination. The most common reason for this test is to look for blood in the upper gastrointestinal tract. Gastric fluid also can be cultured to test for tuberculosis if an adequate sputum sample cannot be obtained for culture.

Semen. More than 10 percent of couples in the United States have difficulty establishing a pregnancy. In addition to obtaining a complete history, performing a physical examination of both partners, and verifying that ovulation does occur in the woman, the physician will perform a semen analysis. Normal semen contains more than 60 million sperm per millilitre. More than 60 percent of the sperm are motile two hours after ejaculation, and 80 to 90 percent will have normal form and structure. Possible causes of infertility are a low sperm count, low motility, or a low percentage of normal forms.

Infertility in men

Miscellaneous tests. *Immunologic procedures.* Immunologic blood tests demonstrate abnormalities of the immune system. Immunity to disease depends on the body's ability to produce antibodies (immunoglobulins) when challenged by foreign substances (antigens). Antibodies bind to and help eliminate antigens from the body.

The inability of the body to produce certain classes of immunoglobulins (IgG, IgA, IgM, IgD, IgE) can lead to disease. Complexes formed by the antigen-antibody reaction can be deposited in almost any tissue and can lead to malfunction of that organ. Immunofluorescence assays to detect antinuclear antibodies (antibodies that will bind to antigens within the nucleus) can be used to diagnose systemic lupus erythematosus and rheumatoid arthritis.

The inability of the body to develop antibodies to invading bacteria may result from infection with HIV, which invades white blood cells—primarily monocytes, macrophages, and helper T lymphocytes. Helper T cells are a subgroup of T lymphocytes that are the primary regulators of the immune response and proliferate in response to antigenic stimulation. Testing for HIV is performed with an enzyme-linked immunosorbent assay (ELISA) and the western immunoblotting antibody test (western blot).

Diabetes mellitus

Oral glucose tolerance test. The glucose tolerance test is used to confirm or exclude the diagnosis of diabetes mellitus when a fasting blood glucose test result is not definitive (*i.e.,* greater than the upper range of the normal value, 115 milligrams per decilitre [mg/dl; 6.4 mmol/l], but less than the diagnostic level for diabetes, 140 mg/dl [7.8 mmol/l]). Even if a blood glucose test is obtained after fasting 10 to 12 hours and the level is above 140 mg/dl, it is important to confirm the result with a second determination to rule out other factors that may have given a one-time abnormal test result.

The oral glucose tolerance test measures the response of the body to a challenge load (an amount calculated to evoke a response) of glucose. It most often is used during pregnancy to detect early glucose intolerance that could pose a significant risk to the infant. After a fasting blood glucose test result is obtained, 75 grams of glucose (100 grams if the patient is pregnant) is administered and blood samples are taken every 30 minutes for two hours. In patients with diabetes, the blood glucose value will rise to a higher level and remain higher longer than in individuals who do not have diabetes.

A simpler but less reliable screening test is the two-hour postprandial blood glucose test, performed two hours after intake of a standard glucose solution or a meal containing 100 grams of carbohydrates. A plasma glucose level above 140 mg/dl indicates the need for a glucose tolerance test.

Gastrointestinal absorption tests. Malabsorption of nutrients can result from surgical alterations or physiological disturbances of the gastrointestinal tract: removal of a significant portion of the bowel can cause the malabsorption condition short-bowel syndrome, a diffuse mucosal disease such as sprue can interfere with absorption, and diseases of the liver or pancreas may prevent digestive enzymes from reaching the intestines. Bacterial overgrowth in the intestines can interfere with glucose absorption, and the stomach's failure to produce intrinsic factor will prevent the absorption of vitamin B_{12} (cobalamin), which leads to pernicious anemia.

Persons who have a low serum vitamin B_{12} level and who are suspected of having pernicious anemia usually are required to undergo the Schilling test. Radioactive vitamin B_{12} is administered orally, and the amount excreted in the urine over the next 24 hours is measured. Malabsorption is confirmed if less than 8 percent of the vitamin B_{12} is excreted in the urine.

Steatorrhea is the excretion of an excessive amount of fat in the stool, which is diagnostic of fat malabsorption when the amount of fat in the diet is normal. Stool specimens are collected for three days following two days of a diet containing 100 grams of fat per day. The excretion of more than six grams of fat daily indicates fat malabsorption, which may occur in persons with pancreatic disease, in those with diffuse mucosal disease, and in those who have undergone massive small-bowel resection.

A five-carbon sugar, D-xylose, is absorbed in the duodenum and proximal jejunum. It is not metabolized and is excreted unchanged in the urine. The D-xylose absorption test measures the absorption ability of the jejunum. Lowered excretion indicates diminished intestinal absorption usually caused by a decreased absorptive surface, infiltrative intestinal disease, or bacterial overgrowth.

Toxicological tests. Toxicology is the study of poisons—their action, detection, and the treatment of conditions they produce. Many substances are toxic only at high concentrations. Lithium, for example, is used to treat bipolar (manic-depressive) disorder but can be toxic at high levels. Another example is acetaminophen, which is valuable in controlling fever and discomfort but is toxic in large doses.

Levels of toxicity

The concentration of an element in the blood is the usual measure of toxicity. The therapeutic blood range is the concentration of the drug that provides therapeutic benefit, whereas the toxic blood range is the concentration at which toxic manifestations are likely.

Some substances such as insecticides are toxic to one individual and not to another. Many environmental substances as well as some encountered in the workplace are toxic in high doses; these include organic solvents, heavy metals, mineral dusts, dyes, and cigarette smoke. Acceptable exposure levels are controlled by government standards.

The nervous system is most sensitive to toxicological damage. Common toxins that cause damage to peripheral nerves are the six-carbon solvents, such as *n*-hexane, in glues or solvents and organophosphorus compounds. Carbon disulfide, used in the production of rayon fibres and cellophane, is a potent neurotoxin. Because no specific treatment is available for most of these toxic manifestations, preventing overexposure is important.

GENETIC TESTING

The diagnostic evaluation of a genetic disorder begins with a medical history, a physical examination, and the construction of a family pedigree documenting the diseases and genetic disorders present in the past three generations. This pedigree aids in determining if the problem is sex-linked, dominant, recessive, or not likely to be genetic.

Chemical, radiological, histopathologic, and electrodiagnostic procedures can diagnose basic defects in patients suspected of genetic disease. These include chromosome karyotyping (in which chromosomes are arranged according to a standard classification scheme), enzyme or hormone assays, amino acid chromatography of blood and urine, gene and deoxyribonucleic acid (DNA) probes, blood and Rh typing, immunoglobulin determination, electrodiagnostics, and hemoglobin electrophoresis.

As a result of genetic mutation, a genetic disorder can occur in a child with parents who are not affected by this disorder. This mutation can occur when the egg or sperm form (germinal mutation), or it can occur later following conception, when chromosomes from the egg and sperm combine. Mutations can occur spontaneously or be stimulated by such environmental factors as radiation or carcinogenic (cancer-causing) agents. Mutations occur with increasing frequency as people age. In men this may result from errors that occur throughout a lifetime as DNA replicates to produce sperm. In women nondisjunction of chromosomes becomes more common later in life, increasing the risk of aneuploidy (too many or too few chromosomes). Long-term exposure to ambient ionizing radiation may cause genetic mutations in either gender.

Cytogenetics

Cytogenetics is the microscopic study of chromosomes and the transmission of genetic material from parent to offspring. Humans have 22 pairs of identical chromosomes plus a pair of sex chromosomes (one inherited from each parent). There are 30,000 to 40,000 genes arranged along the chromosomes in linear order, each having a precise location, or locus. The goal of the international human genome project was to map the location of all genes by the year 2005; a rough map was produced in 2000 and a finished map in 2003. The mapping of specific locations of variations in the human genome will help to identify the genetic causes of a number of diseases.

Two broad classes of genes have been implicated in the development of cancer—oncogenes, which promote tumour growth, and tumour-suppressor genes. Both types of cancer-related genes, usually more than one variation of each type, are involved in a particular cancer, such as that of the colon or breast.

Prenatal diagnosis. Prenatal screening is performed if there is a family history of inherited disease, the mother is at an advanced age, a previous child had a chromosomal

abnormality, or there is an ethnic indication of risk (Ashkenazic Jews and French Canadians are at increased risk for Tay-Sachs disease; blacks, Arabs, Turks, and others for sickle-cell anemia; and those of Mediterranean descent for thalassemia [hereditary anemia]). Parents can be tested before or after conception to determine whether they are carriers.

Alpha-fetoprotein screening

The most common screening test is an assay of alpha-fetoprotein (AFP) in the maternal serum. Elevated levels are associated with neural tube defects in the fetus such as spina bifida (defective closure of the spine) and anencephaly (absence of brain tissue). When alpha-fetoprotein levels are elevated, a more specific diagnosis is attempted using ultrasonography and amniocentesis to analyze the amniotic fluid for the presence of alpha-fetoprotein and acetylcholinesterase. Fetal cells contained in the amniotic fluid also can be cultured and the karyotype (chromosome morphology) determined to identify chromosomal abnormality. Cells for chromosome analysis also can be obtained by chorionic villus sampling, the direct needle aspiration of cells from the chorionic villus (future placenta). (See REPRODUCTION AND REPRODUCTIVE SYSTEMS: *Human reproduction from conception to birth: The normal events of pregnancy: Prenatal care and testing*.)

Chromosomal analysis. To obtain a person's karyotype, laboratory technicians grow human cells in tissue culture media. After being stained and sorted, the chromosomes are counted and displayed. The cells are obtained from the blood, skin, or bone marrow or by amniocentesis or chorionic villus sampling, as noted above. The standard karyotype shown in the procedure has approximately 400 visible bands, and each band contains up to several hundred genes.

When a chromosomal aberration is identified, it allows for a more accurate prediction of the risk of its recurrence in future offspring. Karyotyping can be used not only to diagnose aneuploidy, which is responsible for Down, Turner's, and Klinefelter's syndromes, but also to identify the chromosomal aberrations associated with solid tumours such as Wilms' tumour, meningioma, neuroblastoma, retinoblastoma, renal-cell carcinoma, small-cell lung cancer, and certain leukemias and lymphomas.

DNA probes. Karyotyping requires a great deal of time and effort and may not always provide conclusive information. It is most useful in identifying very large defects involving hundreds or even thousands of genes.

Newer techniques such as fluorescent in situ hybridization (FISH) have much higher rates of sensitivity and specificity. FISH also provides results more quickly because no cell culture is required. This technique can detect smaller genetic deletions involving one to five genes. It is also useful in detecting moderate-sized deletions such as those causing Prader-Willi syndrome, which is characterized by a rounded face, low forehead, and mental retardation.

Gene analysis with recombinant DNA

The analysis of individual genes has been greatly enhanced by the development of recombinant DNA technology. Small DNA fragments can be isolated, and unlimited amounts of cloned material can be produced. Once cloned, the various genes and gene products can be used to study gene function in healthy individuals and those with disease. Recombinant DNA methods can detect any change in DNA, down to a one-base-pair change out of the three billion base pairs in the genome. DNA probes are labeled with radioactive isotopes or fluorescent dyes and used to identify persons who are carriers for autosomal recessive conditions. Disorders that can be detected using this technique include hemophilia A, polycystic kidney disease, sickle-cell disease, Huntington's chorea, cystic fibrosis, and hemochromatosis.

Biochemical tests. Biochemical tests primarily detect enzymatic defects such as phenylketonuria, porphyria, and glycogen-storage disease. Although testing of newborns for all these abnormalities is possible, it is not cost-effective, because some are quite rare. Screening requirements for these disorders vary from state to state and depend on whether the disease is sufficiently common, has severe consequences, and can be treated or prevented if diagnosed early and whether the test can be applied to the entire population at risk.

INSTRUMENTAL SCREENING

Scopes. *Sigmoidoscopy.* Colorectal cancer is the second leading cause of death from cancer in the United States. This disease is preventable if adenomatous polyps, protruding growths from the mucosal surface that can progress to cancer, are identified and removed. Although most adenomatous polyps are not cancerous, this possibility can only be discounted by histologic examination, which requires their removal. Fifty percent of all lesions occur in the rectum and sigmoid colon; they can be detected and removed using a 60-centimetre flexible sigmoidoscope. This instrument consists of a bundle of optical fibres that carry the visual image; it can be bent at the tip in four directions using controls at the base so that it can be maneuvered through the contorted sigmoid colon. The scope also contains a light source at the tip for illuminating the bowel, as well as separate passageways for instilling air and water, for suctioning fluid, and for inserting such instruments as biopsy forceps and snares. This scope has a smaller diameter than do rigid scopes and causes the patient less discomfort because of its flexibility. The operator can see the organ directly through a magnifying eyepiece or indirectly by a video monitor. The latter allows videotaping of suspicious lesions. Both rigid and flexible scopes can be fitted with a still camera.

The flexible fibre-optic sigmoidoscope comes in lengths of 35 and 60 centimetres. When fully inserted, the 60-centimetre scope can reach to the mid-descending colon and is the more frequently used scope. The colonoscope is a similar flexible fibre-optic scope that is longer and can reach the cecum, thus allowing evaluation of the entire colon. Its use requires that the patient be sedated because its passage through the entire colon is more uncomfortable.

A rigid, 25-centimetre sigmoidoscope is less expensive and allows direct visualization of the bowel, but it is less popular because of the greater discomfort its rigidness causes. The proctoscope and anoscope, shorter rigid instruments used to visualize the lower rectum and anus, are used to diagnose and treat hemorrhoids and other lesions in the anorectal area.

Screening for colon cancer

The incidence of colon cancer increases sharply after the age of 50. Asymptomatic individuals should have a sigmoidoscopy at age 50 and, if the result is negative, the test should be repeated every three to five years. Symptomatic persons and those with a family history of colon cancer should start regular examinations at age 40 or younger.

Esophagogastroduodenoscopy. As the lengthy name implies, esophagogastroduodenoscopy (EGD) is an endoscopic examination in which a scope is passed through the esophagus, stomach, and duodenum for a visual examination. This flexible fibre-optic scope contains the same channels as the flexible fibre-optic sigmoidoscope described above and usually has a camera attached to record visually recognizable abnormalities.

This procedure is indicated when symptoms of peptic ulcer disease persist despite an adequate trial of treatment or when there is upper gastrointestinal bleeding or a suspicion of upper gastrointestinal cancer. It is also indicated if there is an esophageal stricture or obstruction or persistent vomiting of unknown cause. Esophageal strictures, if benign, can be successfully dilated, and upper gastrointestinal bleeding can be controlled using electrocoagulation. If the bleeding is from esophageal varices, they can be injected with a sclerosing (hardening) agent. A tissue sample can be removed and examined (a biopsy) from any suspicious lesion of the esophagus, stomach, or duodenum to make the specific tissue diagnosis that is necessary when deciding on the most appropriate therapy.

Endoscopic retrograde cholangiopancreatoscopy. The flexible fibre-optic scope used in endoscopic retrograde cholangiopancreatography (ERCP) is similar to the scopes described above. It is passed through the stomach into the duodenum to visualize the ampulla of Vater, the opening of the common bile duct into the duodenum. It enables injection of a radiopaque dye into the common bile duct to permit radiographic visualization of the common bile duct and the pancreatic duct. This test is used to evaluate the patient with jaundice whose biliary tract is suspected to be obstructed because of a gallstone or tumour. It is also used

to evaluate persistent pancreatitis of unknown cause. If there is stricture of the ampulla or another area in the common bile duct, a sphincterotomy (incision of the sphincter) or balloon dilatation can be used to enlarge the opening.

Laparoscopy. Fibre-optic technology has greatly expanded the procedures that can be performed by laparoscopy. By using local anesthesia and mild sedation, the abdominal wall can be punctured and the laparoscope inserted to examine the contents of the abdomen, obviating the need for major surgery and general anesthesia. Instruments are inserted through multiple ports in the abdomen, and surgeons can visualize abdominal organs without making an open incision into the abdomen. Valuable diagnostic information can be obtained by examining a biopsy specimen of the liver or abdominal lesions. Surgeons also can perform a variety of procedures with this method, such as removing the gallbladder and ligating the fallopian tubes. In orthopedic surgery the same technique is called arthroscopy, and it simplifies the treatment of many disorders that previously required a large surgical incision and a lengthy period of rehabilitation.

Alternative to major surgery

Nasopharyngolarygoscopy. The use of fibre-optic nasopharyngolaryngoscopes permits visualization of structures inside the nasal passages such as the sinus openings, larynx, and vocal cords. A more thorough examination can be performed than is possible using indirect visualization with a mirror.

Colposcopy. The colposcope is a lighted magnifying scope used to directly visualize the vulva, vagina, and cervix and to evaluate suspicious areas. Colposcopy is used when the Papanicolaou test suggests the possibility of cancer; it helps to detect precancerous abnormalities and identifies in which areas a biopsy should be performed for a definitive diagnosis to be made.

Graphing and miscellaneous instrumental screening. *Electroencephalogram.* The electroencephalogram (EEG) is a record of electrical activity of the brain recorded by 8 to 16 pairs of electrodes attached to the scalp. It is useful in the diagnosis of epilepsy, brain tumours, and sleep disorders and in the assessment of patients with suspected brain death. The latter use is particularly important if organs are to be saved for transplantation as soon as brain death is confirmed. Sleep deprivation and other provocative tests, including photic stimulation and hyperventilation, can be used to accentuate borderline findings. The EEG is of no use in diagnosing psychiatric illness.

Electrocardiogram. The electrocardiogram (ECG) is a graphic recording of the electrical activity of the heart detected at the body surface and amplified. It was invented by the Dutch physiologist Willem Einthoven (1860–1927) and for many years was called an EKG after the German *Elektrokardiogramm*. Electrodes to record the electrical activity of the heart are placed at 10 different locations, one on each of the four limbs and six at different locations on the anterior chest wall. Twelve different leads, or electrical pictures, are generated, each having its own normal configuration.

Evaluating the heart

The ECG is of greatest use in diagnosing cardiac arrhythmias, acute and prior myocardial infarctions, pericardial disease, cardiac enlargement (atrial and ventricular), and various electrolyte disturbances and drug effects. The exercise electrocardiogram, or ECG stress test, is used to assess the ability of the coronary arteries to deliver oxygen while the heart is undergoing strain imposed by a standardized exercise protocol. If the blood supply to the heart is jeopardized during exercise, the inadequate oxygenation of the heart muscle is recorded by typical changes in the electrocardiogram that indicate coronary artery disease (narrowing of the coronary arteries).

Echocardiography. The echocardiogram is a noninvasive technique used to record the structure of the heart by using ultrahigh-frequency sound waves. A transducer placed on the chest wall emits a short burst of ultrasound waves and then measures the reflection, or echo of the sound as it bounces back from such cardiac structures as valves and the muscle wall. It is used to evaluate chamber size, wall thickness, wall motion, valve structure, and valve motion. It is the method of choice for detecting infection of the valves (endocarditis), intracardiac tumours, and pericardial fluid. Mitral valve prolapse is easily visualized by this noninvasive technique.

Myocardial perfusion imaging. Myocardial perfusion imaging uses radioactive thallium to detect myocardial ischemia, myocardial infarction, and coronary artery disease. Injected intravenously, radioactive thallium is rapidly absorbed by the myocardium and is normally distributed evenly in heart muscle. Deficient blood flow to a portion of the myocardium is readily detectable by decreased uptake in that area. Evidence of recent and not-so-recent myocardial infarcts will be visible, but most persons with coronary artery disease who have not had a previous infarction will have normal perfusion patterns when they are at rest. In such a patient a thallium stress test is performed in which the substance is injected while the individual is exercising so that areas of transient ischemia can be identified and the patient treated to prevent myocardial infarction. An alternative means of stressing the heart that can provide information comparable with exercise is the injection of dipyridamole, a vasodilator. This test is used to diagnose coronary artery disease when the resting electrocardiogram is abnormal or the exercise electrocardiogram is equivocal.

Another method for evaluating the heart without the stress of exercise involves the intravenous injection of the drug dobutamine, while monitoring the effects using echocardiography. By using dobutamine echocardiography, the heart condition of frail patients and those who have heart disease or physical limitations that preclude exercise can be evaluated. Dobutamine induces the same changes in the heart that would occur during a standard exercise test. Two-dimensional echocardiography shows areas of the left ventricle that function abnormally. This technique uses no X-ray or radioactive material and is useful in diagnosing heart disease during pregnancy (see above *Echocardiography*).

Cardiac catheterization and angiography. A more specific measurement of coronary artery narrowing is carried out by placing a catheter into the heart though which a radiopaque dye is injected, allowing the cardiac chambers and coronary arteries to be directly visualized. This test is more expensive and more hazardous than the noninvasive procedures and is usually performed after the others to quantify the severity of disease present and to establish whether the person is a candidate for surgical intervention with balloon angioplasty or coronary bypass surgery. It is also used to evaluate patients with suspected valvular disease and those with angina who do not respond to treatment.

Electromyography. Electromyography (EMG), the graphing and study of the electrical characteristics of muscles, is used to differentiate disease of the muscles from disease of the peripheral nerves. A needle electrode is inserted into the muscle, and the electrical activity of the muscle is measured. Resting muscle is normally electrically silent. The electrical potential is measured with the muscle at rest and during contraction. The response to electrical stimulation allows the physician to determine whether muscle weakness is the result of a disease in the muscle, such as a myositis (inflammation of the muscle), or a disease of nerves leading to muscle (neuropathy), such as Guillain-Barré syndrome.

Diagnosing muscle disorders

SURGICAL EXAMINATION

Biopsy. A biopsy is the removal of tissue for microscopic examination to establish a precise diagnosis. Tissue can be obtained from any organ by excision, incision, removal by a needle, or scraping. Glass slides of the tissue are prepared and examined microscopically to define the characteristic nature of the lesion.

An excisional biopsy is the total removal of the lesion to be examined and is most often used to diagnose skin lesions. The major advantage of excisional biopsy is that it provides the pathologist with the entire lesion and minimizes the chance that a cancer in part of the lesion would be missed. This technique is practical only when the lesion is accessible and is less than two or three centimetres in diameter.

An incisional biopsy involves the removal of only a por-

tion of the lesion for pathological examination and is used when the size or location of the tumour prohibits its complete excision. This technique also is used when a needle biopsy does not provide adequate information for a diagnosis to be made.

A needle biopsy is the simplest and least disruptive way to obtain tissue for pathological examination. This procedure can be performed using either a large cutting needle to obtain a "core" of tissue or a small-gauge needle. The latter technique, termed fine-needle aspiration biopsy, is accomplished by inserting the needle into the area of interest and applying suction to draw the tissue into the needle. A needle biopsy is often used to obtain specimens from breast masses. It is less expensive and involves less morbidity than does an open biopsy. The main disadvantages include the missing of deep lesions with the needle and the need for a specially trained pathologist to accurately interpret the specimen. As noted above, often more cells are needed for a precise diagnosis than are provided by a fine-needle biopsy.

Fine-needle aspiration biopsy

Another form of aspiration biopsy is the endometrial biopsy, in which the specimen is obtained by applying suction through a curette inserted into the uterus to obtain cells from the internal lining.

Abrasion is a method by which cells are obtained from the surface of lesions using a brush or spatula. Cells from epithelial-lined body cavities and surfaces such as the vagina, bronchus, and stomach are examined using the Papanicolaou technique. The Papanicolaou test or smear, commonly called the Pap smear, is the examination of cervical cells that have been fixed and stained on a slide according to the technique developed by the Greek physician George Nicolas Papanicolaou. This technique also can be applied to cells obtained from other surfaces.

Exploratory surgery. When a specific diagnosis is not possible using noninvasive or simple biopsy techniques, it may be necessary to surgically explore the area in question. If the lesion is in the abdomen, this involves a laparotomy or incision into the abdomen to observe the lesion. If possible a biopsy sample is removed. It may be apparent that the lesion is inoperable because of its location or attachment to vital structures from which it cannot be separated.

RADIOLOGICAL SCREENING

Named after Wilhelm Conrad Röntgen, the roentgenogram is the photograph of internal structures made by passing X rays through the body to produce a shadow image on specially sensitized film. The value of a roentgenogram is considerably enhanced by the use of contrast material, such as barium, to make structures visible on the film that would otherwise not appear. Perhaps the most common procedure employs a barium enema, administered to the patient before the X-ray examination, which allows identification of polyps as small as one centimetre in diameter when air is inserted after the barium (a double-contrast barium enema). This screening is effective if precancerous polyps are identified at an early stage.

Chest film. One of the most common screening roentgenograms is the chest film, taken to look for such infections as tuberculosis and conditions like heart disease and cancer. Treatment of tuberculosis detected by a roentgenogram can prevent more extensive infection, but unfortunately this technique is of little value in screening for lung cancer because the stage at which the disease is detectable by this method is too far advanced for treatment to be of value.

Screening for breast cancer

Mammography. New film screening techniques make it possible to detect lesions in the breast using low doses of radiation. Mammography is never a substitute for a clinical breast examination by a physician, because not all lesions are detectable by X-ray examination; however, lesions often can be detected by mammography before they are palpable in the breast. The primary purpose for mammography is the detection of cancer at the earliest, treatable stage, before the lesion is palpable.

Mammography is most useful in older women whose breast tissue is less dense than that of younger women. Mammography is never a substitute for a biopsy if a suspicious mass is palpated. Some groups recommend an initial mammogram at 35 to 40 years of age to serve as a baseline for subsequent screening. The American Cancer Society recommends a mammogram every one to two years from age 40 to 49 and yearly thereafter. However, women at increased risk for breast cancer should consider initiating annual mammographic screening before the age of 40. The risk of breast cancer is doubled or trebled in women who have a sister with breast cancer or whose mother was diagnosed with breast cancer before the age of 40.

COMPUTERIZED BODY SCANNING

Computed tomography. The introduction of computed tomography (CT scan) in 1972 was a major advance in visualizing almost all parts of the body. Particularly useful in diagnosing tumours and other space-occupying lesions, it uses a tiny X-ray beam that traverses the body in an axial plane. Detectors record the strength of the exiting X rays; this information is then processed by a computer and a cross-sectional image of the body produced.

CT is the preferred examination for evaluating stroke, particularly subarachnoid hemorrhage, as well as abdominal tumours and abscesses.

Ultrasonography. Ultrasonography, or ultrasound imaging, uses pulsed or continuous high-frequency sound waves to image internal structures by recording the differing reflection signals. The sonographic image is not as precise as images obtained through computed tomography or magnetic resonance imaging, but it is used in many procedures because it is quick and relatively inexpensive and has no known biological hazards when used within the diagnostic range.

Advantages of ultrasound

This method is used to diagnose gallstones, heart defects, and tumours. It is used to guide certain procedures such as needle biopsies and the introduction of tubes for drainage. It has become an essential part of obstetric and prenatal assessment, although controversy exists as to its routine use in obstetric care. Ultrasonography plays an integral role in the diagnosis and management of fetal abnormalities; it is also used to guide intrauterine corrective surgery.

Magnetic resonance imaging. Magnetic resonance imaging (MRI) relies on the response of magnetic fields to short bursts of radio-frequency waves to produce computer images that provide structural and biochemical information about tissue. The process uses radio waves and is thus much safer than imaging using X rays or gamma rays. This totally noninvasive but very expensive procedure is particularly useful in detecting cerebral edema, abnormalities of the spine, and early-stage cancer. In examining the brain, spinal cord, urinary bladder, pelvic organs, and cancellous bone, MRI is the superior imaging technique. Because patients must lie quietly inside a narrow tube, MRI may raise anxiety levels in the patients, especially those with claustrophobia. Another disadvantage of MRI is that it has a longer scanning time than CT, which makes it more sensitive to motion artifacts and thus of less value in scanning the chest or abdomen. Because of the strong magnetic field, MRI cannot be used if a pacemaker is present or if metal is present in critical areas such as the eye or brain.

MRI has largely supplanted arthrography, the injection of dye into a joint to visualize cartilage or ligament damage to the knee or shoulder, and myelography, the injection of dye into the spinal canal to visualize spinal cord or intervertebral disk abnormalities.

Multiple sclerosis, a disease with multiple foci of demyelination (loss of the myelin sheath of a nerve) in the brain, sometimes can be diagnosed using MRI. However, because the test is not sufficiently sensitive, a normal MRI cannot exclude the diagnosis.

Magnetic resonance angiography, a unique form of MRI technology, can be used to produce an image of flowing blood. This permits the visualization of arteries and veins without the need for needles, catheters, or contrast agents.

CT and MRI provide two-dimensional views of cross sections of the body, and these images must be viewed in sequence by the radiologist. Computer technology now makes it possible to construct holograms that provide three-dimensional images from digital data obtained by conventional CT or MRI scanners. These holograms can

Three-dimensional images

be useful in locating lesions more precisely and in mapping the exact location of coronary arteries when planning bypass surgery or angioplasty.

Digital subtraction angiography. Digital subtraction angiography (DSA), an electronic technique for imaging blood vessels, is useful in diagnosing arterial occlusion, including carotid artery stenosis and pulmonary artery thrombosis, and in detecting renal vascular disease. After contrast material is injected into an artery or vein, a physician produces fluoroscopic images. Using these digitized images, a computer subtracts the image made with contrast material from a postinjection image made without contrast material, producing an image that allows the dye in the arteries to be seen more clearly. In this manner, the images arising from soft tissues, bones, and gas are the same in the initial and subsequent image and are thereby eliminated by the subtraction process. The remaining images of blood vessels containing the contrast material are thus more prominent.

Positron emission tomography. Positron emission tomography (PET) is a highly sensitive technique for diagnosing stroke and other neurological diseases such as multiple sclerosis and epilepsy. Positron-emitting radionuclides with short half-lives are used to detect cerebral blood flow, oxygen utilization, and glucose metabolism, providing both qualitative and quantitative information regarding metabolism and blood flow, such as in the heart.

Formulating a diagnosis

The process of formulating a diagnosis is called clinical decision making. The clinician uses the information gathered from the history and physical examination to develop a list of possible causes of the disorder, called the differential diagnosis. The clinician then decides what tests to order to help refine the list or identify the specific disease responsible for the patient's complaints. During this process, some possible diseases (hypotheses) will be discarded and new ones added as tests either confirm or deny the possibility that a given disease is present. The list is refined until the physician feels justified in moving forward to treatment. Even after treatment is begun, the list of possible diagnoses may be revised further if the patient does not progress as expected.

The differential diagnosis

The hypotheses are ranked with the most likely disease placed first. Sometimes, however, a less likely disease is addressed first because it is more life-threatening and could lead to serious consequences if not treated promptly. Following this course, the possibility of a heart attack would be eliminated first in a patient experiencing chest pain and appendicitis would be the first condition to be addressed in a child with abdominal pain, even though another less serious disease is more likely.

An algorithm is a sequence of alternate steps that can be taken to solve problems—a decision tree. Starting with a chief complaint or key clue, the physician moves along this decision tree, directed one of two ways by each new piece of information, and eliminates diagnoses. If the wrong path is taken, the physician returns to a previous branching point and follows the other path. Computers can be used to assist in making the diagnosis; however, they lack the intuition of an experienced physician and the nonverbal diagnostic clues obtained during the interview.

Diagnostic tests rarely establish the presence of a disease without doubt. The greater the sensitivity and the specificity of the test, the more useful it will be. Ordering too many tests poses significant danger, not only because of low cost-effectiveness but also because a falsely abnormal test result requires a further series of tests to prove or disprove its accuracy. This further testing may involve additional discomfort, risk, and cost to the patient, which is especially unfortunate if the tests need not have been ordered in the first place. It is just as important to know when not to order a test as to know which tests to order.

An important feature of clinical decision making is the ongoing relationship between the physician and patient. The knowledge a physician gains in caring for the patient for a long period of time can provide greater insight into the likelihood of a given disease being present. When the symptoms are caused by emotional factors, the familiar personal physician is more likely to accurately diagnose them than is a physician seeing the patient for the first time. Also, a lengthy and trusting association with a physician will often positively influence the patient's outcome. Thus, sporadic visits to the emergency department of a hospital, where physicians who are unfamiliar with the patient are asked to provide diagnoses and treatment without the benefit of this partnership, are more likely to be inefficient, expensive, and less personally satisfying.

Physician-patient relationship

Early in the course of a disease, decisions must be made with fewer clues to the diagnosis than are likely to be available later. One of the most difficult tasks in medicine is to separate, in the early stages of an illness, the serious and life-threatening diseases from the transient and minor ones. Many illnesses will resolve without a diagnosis ever being reached. Nevertheless, an illness may remain undiagnosed for months or years before new symptoms appear and the disease advances to a stage that permits diagnosis.

Patients often have undifferentiated complaints that can represent an uncommon serious disorder or a common but not very serious disorder. For example, a patient may experience fatigue. Depending on the patient's family history and personal background, the physician may think initially of depression and next of anemia secondary to gastrointestinal bleeding. A variety of less likely disorders will follow. Anemia is easy to rule out with inexpensive hemoglobin and hematocrit tests. These tests should be ordered even if depression is the correct diagnosis because anemia may contribute to the weariness and should be treated as well. Depression can be diagnosed with appropriate questioning, and a physical examination may eliminate many other diagnostic possibilities.

THERAPEUTICS

Preventive medicine

The rationale for preventive medicine is to identify risk factors in each individual and reduce or eliminate those risks in an attempt to prevent disease. Primary prevention is the preemptive behavior that seeks to avert disease before it develops—for example, vaccinating children against diseases. Secondary prevention is the early detection of disease or its precursors before symptoms appear, with the aim of preventing or curing it. Examples include regular cervical Papanicolaou test screening and mammography. Tertiary prevention is an attempt to stop or limit the spread of disease that is already present. Clearly, primary prevention is the most cost-effective method of controlling disease.

The five leading causes of death in the United States are cardiovascular disease, cancer, cerebrovascular disease, accidental injuries, and chronic lung disease. The single most preventable cause of death in the United States is cigarette smoking, which is linked to cardiovascular disease (heart attack), cancer (lung, larynx, bladder, pancreas, and so on), cerebrovascular disease (stroke), and chronic lung disease (emphysema, chronic bronchitis).

Leading causes of death in the United States

Following earlier work by the Canadian Task Force on the Periodic Health Examination, the U.S. Preventive Services Task Force was established to evaluate the effectiveness of various screening tests, immunizations, and prophylactic regimens based on a critical review of the scientific literature. Its report, *Guide to Clinical Preventive Services,* lists the recommendations for the 60 target conditions evaluated by the panel.

Immunization is the best method for preventing infectious diseases. Standard immunizations of infants and children include those for diphtheria, tetanus, and pertussis (DTP); polio (OPV); measles, mumps, and rubella (MMR); *Haemophilus influenzae* type b (HbCV); and hep-

atitis B (HBV). A yearly vaccine against the influenza virus should be administered to adults who are older than 65 years of age, to those at risk because of chronic cardiopulmonary disease, and to those in chronic care facilities. Adults also should be immunized once at age 65 years against pneumococcal pneumonia with a vaccine containing 23 of the most common strains of *Streptococcus pneumoniae*.

Acquired immunodeficiency syndrome (AIDS), caused by the human immunodeficiency virus (HIV), is also a major infectious disease problem. Although a vaccine is expected, obstacles to its development are great. The only primary preventive measures currently available are either to abstain from sexual contact or to use condoms and, among intravenous drug users, to avoid sharing needles. Almost 25 percent of adult AIDS cases in the United States are related to infection from needles used to administer illegal drugs.

Preventing the spread of AIDS

The risk factors for coronary artery disease that can be modified to prevent myocardial infarction are cigarette smoking, hypertension, an elevated serum cholesterol level, a sedentary lifestyle, obesity, stress, and excessive alcohol consumption. In addition to an elevated total serum cholesterol level, an elevated low-density lipoprotein (LDL) level and a decreased high-density lipoprotein (HDL) level are significant risk factors. The total cholesterol level and elevated LDL level can be reduced by appropriate diet, whereas a low HDL can be raised by stopping smoking and increasing activity. If these measures do not provide adequate control, a variety of drugs capable of lowering the cholesterol level are available.

The major risk factor for stroke is hypertension, with cigarette smoking and diabetes mellitus significantly increasing the risk. Transient ischemic attacks (TIAs) occur before stroke in 20 percent of patients and consist of sudden onset of one or more of the following symptoms: temporary loss of vision in one eye, unilateral numbness, temporary loss of speech or slurred speech, and localized weakness of an arm or leg. Attacks last less than 24 hours and resolve without permanent damage until the stroke occurs.

Relation of smoking and cancer

The most important preventive behaviour in averting cancer is the avoidance of cigarette smoke. Smoking accounts for 30 percent of all cancer deaths, and there is increasing recognition of the danger of environmental or sidestream smoke to the nonsmoker. Primary prevention of skin cancer includes restricting exposure to ultraviolet light by using sunscreens or protective clothing. Secondary preventive measures include mammography, clinical breast examinations, and breast self-examinations for breast cancer; pelvic examinations and Papanicolaou tests for cervical and ovarian cancer; and sigmoidoscopy, digital rectal examinations, and stool tests for occult blood for colorectal cancer.

Demineralization of bone and a reduction in bone mass (osteoporosis) occur most often in men and women age 70 or older and may result in fractures, low back pain, and loss of stature. Osteoporosis in postmenopausal women that is caused by estrogen deficiency is the most common manifestation. The most effective method for preventing loss of bone mass after menopause is estrogen replacement therapy and increased calcium intake. Primary preventive measures include increasing physical activity and avoiding cigarettes and heavy alcohol consumption.

Alcohol abuse is the primary reason that accidents are the fourth leading cause of death in the United States. Other factors are failure to wear seat belts or motorcycle helmets, sleep deprivation, and guns in the home. Taking reasonable precautions and being aware of the potential dangers of alcohol and firearms can help reduce the number of deaths due to accidents.

Treatment of symptoms

PAIN

Pain is the most common of all symptoms and often requires treatment before its specific cause is known. Pain is both an emotional and a physical experience and is difficult to compare from one person to another. One patient may have a high pain threshold and complain only after the disease process has progressed beyond its early stage, while another with a low pain threshold may complain about pain that would be ignored or tolerated by most people. Pain from any cause can be increased by anxiety, fear, depression, loneliness, and frustration or anger.

Acute and chronic pain

Acute pain serves a useful function as a protective mechanism that leads to the removal of the source of the pain, whether it be localized injury or infection. Chronic pain serves a less useful function and is often more difficult to treat. Although acute pain requires immediate attention, its cause is usually easily found, whereas chronic pain complaints may be more vague and difficult to isolate.

The ideal method for treating pain is to eliminate the cause, such as to surgically remove an inflamed structure, to apply hot compresses to a muscle spasm, or to set a fractured bone in a cast. Alternatives to drug therapy, such as physical therapy, should be relied on whenever possible. The analgesic drugs most often used to alleviate mild and moderate pain are the nonsteroidal anti-inflammatory drugs (NSAIDs) such as aspirin, ibuprofen, acetaminophen, or indomethacin. If these are ineffective, a weak opiate such as codeine, hydrocodone, or oxycodone would be the next choice. Severe pain not controlled by these agents requires a strong opiate such as morphine or meperidine. Because opiates are addictive, their use is controlled by the Controlled Substances Act, and individuals prescribing or dispensing these drugs must register annually with the Drug Enforcement Administration. Each drug is assigned to one of five groups, from schedule I, which includes drugs that have the highest potential for abuse, to schedule V, which includes drugs with a limited dependence-causing potential.

NAUSEA AND VOMITING

Nausea and vomiting are common symptoms that may arise from diseases of the gastrointestinal tract, including gastroenteritis or bowel obstruction, from medications, such as analgesics or digoxin, or from nervous system disturbances such as migraine headaches or motion sickness. Vomiting is controlled by a vomiting centre located in the medulla oblongata of the brain stem.

Identifying and treating the cause is important, especially if the condition responds well to treatment and is serious if not addressed. A bowel obstruction can occur as a result of adhesions from previous abdominal surgery. Obstruction or decreased bowel motility also can occur with constipation and fecal impaction. Such important and treatable causes must be ruled out before resorting to antiemetic (serving to prevent or cure vomiting) drugs. The most frequently used antiemetic agents are the phenothiazines, the most popular being prochlorperazine (Compazine [trademark]). Antihistamines may be useful in motion sickness, but newer and more powerful drugs are needed to control the vomiting associated with cancer chemotherapy.

Nausea and vomiting are experienced by more than 50 percent of pregnant women during the first trimester. These symptoms are referred to as morning sickness, although they can occur at any time of the day. They may be distressing, but they cause no adverse effect on the fetus. Drug therapy is not only unnecessary; it should be avoided unless proved safe for the fetus. Treatment involves rest and intake of frequent small meals and pyridoxine (vitamin B_6).

Treatment of morning sickness

DIARRHEA

Acute diarrhea can result from food poisoning, laxatives, alcohol, and some antacids but usually is caused by an acute infection with bacteria such as *Escherichia coli, Salmonella,* and *Staphylococcus aureus.* In infants, acute diarrhea is usually self-limiting, and treatment consists primarily of preventing dehydration. Traveler's diarrhea affects up to half of those traveling to developing areas of the world. Preventive measures include chewing two tablets of bismuth subsalicylate (Pepto-Bismol [trademark]) four times a day, drinking only bottled water or other bottled or canned beverages, and eating only those fruits that have been peeled, canned products, and restaurant food that is piping hot. Avoiding dairy products, raw seafood

and vegetables, and food served at room temperature also limits exposure. Severe cases require antibiotic therapy.

COUGH

Coughing is a normal reflex that helps clear the respiratory tract of secretions and foreign material. It also can result from irritation of the airway or from stimulation of receptors in the lung, diaphragm, ear (tympanic membrane), and stomach. The most common cause of acute cough is the common cold. Chronic cough is most often caused by irritation and excessive mucus production that results from cigarette smoking or from postnasal drainage associated with an allergic reaction.

Treatment includes humidification of the air to loosen secretions and to counteract the drying effect of coughing and inflammation. Moist air from a vaporizer or a hot shower helps, as do hot drinks and soups. Antihistamines are often used to treat acute cough, but their value is questionable if an allergy is not present. They may also cause additional drying of the respiratory mucosa. Guaifenesin is widely used in cough preparations to help liquefy secretions and aid expectoration. Decongestants reduce secretions by causing vasoconstriction of the nasopharyngeal mucosa. The most common decongestants found in many cough preparations are pseudoephedrine, phenylephrine, and phenylpropanolamine. They may cause high blood pressure, restlessness, and urinary retention and should be used with caution in anyone being treated for hypertension. Narcotics are powerful cough suppressants, codeine being the most frequently used. Several safer nonnarcotic antitussive (cough-preventing) agents are available such as dextromethorphan, which has almost equal effectiveness but fewer side effects. Most cough preparations containing dextromethorphan also contain a decongestant and an expectorant. Because coughing is an important defense mechanism in clearing secretions from blocked airways, a productive cough (one that produces secretions) should not be suppressed.

Side effects of cough preparations

INSOMNIA

Insomnia is a difficulty in falling asleep or the feeling that sleep is not refreshing. Transient insomnia occurs when there are stressful life events or schedule changes, as shift workers or those who travel across multiple time zones experience. A disturbed sleep can also be related to the intake of stimulating drugs, anxiety, depression, or medical conditions associated with pain. Anxiety usually causes difficulty in falling asleep, whereas depression is associated with early morning awakening. The elderly spend less time sleeping, and their sleep is lighter and marked by more frequent awakenings. This situation is exacerbated by afternoon napping.

The treatment of insomnia involves establishing good sleep hygiene: maintaining a consistent schedule of when to retire and awaken, setting a comfortable room temperature, and minimizing such disruptive stimuli as noise and light. Daily exercise is beneficial but should be avoided immediately before bedtime. Stimulants should be avoided, including nicotine and caffeine. Alcohol disrupts the normal sleep pattern and should also be avoided. Drinkers sleep more lightly and frequently awaken unknowingly, which leaves them feeling unrefreshed the next day.

When medication is required, physicians usually prescribe one of the sleep-inducing benzodiazepines. They may have long-, intermediate-, or ultrashort-acting effects. None should be used regularly for long periods. Various nonbenzodiazepine hypnotics and sedatives are also available, and their usefulness varies according to individual preference.

Designing a therapeutic regimen

Once the physician makes a diagnosis or identifies the most likely cause of the symptoms and decides on the appropriate treatment, an entirely new set of conditions becomes operative. One of the first conditions to be considered is the patient's reason for seeking medical advice and the patient's expectations. The patient's visit may have been precipitated by the discovery that a friend's minor symptom, similar in nature to one the patient has been experiencing, proved to be something serious. If tests can rule out this possibility, reassurance may serve as a therapeutic action. When possible, physicians work to cure a disease and thereby relieve the symptoms, but many times the disease is unknown or chronic and incurable. In either case, relief from or improvement of symptoms or restoration of normal functioning is the goal. When neither a cure nor complete relief of symptoms is possible, an explanation of the disease and knowledge of the cause and what to expect may provide significant relief. Patients often want to know the name of the disease, what caused it, how long it will last, what additional symptoms may occur, and what they can do to assist the physician's treatment to hasten recovery. Providing information about the disease can help to alleviate anxiety and fears that could otherwise impede the patient's progress.

Attention to the patient's emotional well-being

An essential ingredient of any successful therapeutic regimen is the positive attitude of the patient toward the physician. A relationship of trust and respect for the physician based on reputation or years of supportive care is one of the physician's most powerful therapeutic tools.

When selecting a management plan, the physician usually has several options, and the outcomes or consequences of each will vary. Often, the best choice is one made together with the patient, who may have definite preferences for a trial of therapy over further testing or for oral medication rather than an injection, even if the latter would provide more rapid relief. The possible side effects of the medicine or treatment may well influence therapeutic choice, such as if a person would prefer dizziness to nausea. Once a course of therapy is selected, a new decision tree arises that leads to new options, depending on the response. Further testing, increasing the dose of medication, or changing to a new drug may be required. Almost every treatment has some degree of risk, from either unwanted side effects or unexpected complications. The physician describes these risks in terms of probability, expecting the patient to accept or reject the treatment based on these odds and his or her willingness to suffer the side effects or to risk the complications to achieve relief.

Another factor affecting therapeutic success is patient compliance—the degree to which patients adhere to the regimen recommended by their physician. Therapeutic regimens that require significant changes in lifestyle, such as recommendations to follow a special diet, begin an exercise program, or discontinue harmful habits like smoking cigarettes, are likely to result in poor compliance. Also, the greater the number of drugs prescribed and the more complicated the regimen, the poorer is the compliance. A patient is much more likely to successfully follow a regimen of taking a single dose of medication daily than one prescribed four times daily. Patients also may not fully realize the need to continue taking the medication after their symptoms have subsided, despite a physician's instruction to finish the medicine. Patient compliance may be most difficult to achieve in chronic but generally asymptomatic illnesses such as hypertension. Patients who experience no symptoms may need to be convinced of the necessity of taking their medication daily to prevent the occurrence of an untoward event (in hypertension, a stroke or other cardiovascular problems). Similarly, patients with depression or anxiety may want to discontinue medication once their symptoms abate. Until a relapse occurs, they may not recognize the need to continue taking the medication until instructed to taper the dosage slowly.

Adhering to the therapeutic regimen

In deciding which therapeutic regimen is likely to be most effective, the physician must depend on scientific studies that compare one drug or treatment regimen with others that have been proved effective. The most dependable study is one that is truly objective and removes the possibility of bias on the part of the patient who wants the drug to work and the bias of the physician who may expect a certain outcome and subtly influence the interpretation. Such a study is "double-blind": it controls for both possible tendencies by comparing an active drug with an inactive "look-alike" drug. Neither the patient nor the physician knows which drug the patient is taking, so that neither one's bias can influence the result. Although this is

The double-blind study

the best way to demonstrate the effectiveness of a drug, it is sometimes very difficult to control for all the variables that could influence the outcome, such as varying degrees of stress one group or another may be under. Physicians will use the results of a wide variety of studies similar to this study to decide whether a regimen or drug is likely to work in a given patient; however, they will depend most heavily on their past experience with drugs or other techniques that have worked under similar circumstances. It is knowledge based on experience and on understanding of the patient that leads to the greatest therapeutic success.

Diet

PROPHYLACTIC MEASURES OF NUTRITION

General requirements. Adequate nutritional intake is required to maintain health and prevent disease. Certain nutrients are essential; without them a deficiency disease will result. Required nutrients that cannot be synthesized by the body and therefore must be taken regularly are essential amino acids, water-soluble and fat-soluble vitamins, minerals, and essential fatty acids. The U.S. Recommended Dietary Allowances (RDAs), one of many sets of recommendations put out by various countries and organizations, have been established for these essential nutrients by the Food and Nutrition Board of the National Academy of Sciences. These RDAs are guidelines and not absolute minimums. Intake of less than the RDA for a given nutrient increases the risk of inadequate intake and a deficiency disorder. Nutritional requirements are greater during the periods of rapid growth (infancy, childhood, and adolescence) and during pregnancy and lactation. Requirements vary with physical activity, aging, infections, medications, metabolic disorders (*e.g.,* hyperthyroidism), and other medical situations. RDAs do not address all circumstances and are designed only for the average healthy person.

Protein, needed to maintain body function and structure, consists of nine essential amino acids that must be provided from different foods in a mixed diet. Ten to 15 percent of calories should come from protein. The oxidation of 1 gram (0.036 ounce) of protein provides 4 kilocalories of energy. The same is true for carbohydrate, but fat yields 9 kilocalories.

Carbohydrate provides about 45 percent of calories in the American diet, in the form of sugars, starches (complex carbohydrates), and dietary fibre (indigestible carbohydrates). Fibre is not digestible but increases the bulk of the stool and facilitates faster intestinal transit, which some believe reduces the risk of colon cancer by diminishing the time that cancer-producing substances in the diet remain in contact with the bowel wall. Increasing bulk also decreases the concentration of these substances. Dietary fibre can be insoluble (wheat bran) or soluble (oat bran and psyllium). Only the soluble fibres found in oats, fruit, and legumes lower blood cholesterol and benefit individuals with diabetes by delaying the absorption of glucose.

The most concentrated source of energy is fat, the source of fat-soluble vitamins and essential fatty acids. Thirty-seven percent of calories in the American diet come from fat, but the ideal is closer to 30 percent. The average American diet also contains 450 milligrams daily of cholesterol, but less than 300 milligrams is recommended.

Food Guide Pyramid

The recommended daily diet as determined by the U.S. Department of Agriculture is called the Food Guide Pyramid and consists of 6 to 11 servings of bread, cereal, rice, or pasta; 3 to 5 servings of vegetables; 2 to 4 servings of fruit; 2 to 3 servings of fish, meat, poultry, dry beans, eggs, or nuts; and 2 to 3 servings of milk, yogurt, or cheese.

Requirements in infancy. Nutritional needs are greatest during the first year of life. Meeting the energy demands during this period of rapid growth requires 100 to 120 kilocalories per kilogram per day. Breast milk, the ideal food, is not only readily available at the proper temperature, it also contains antibodies from the mother that help protect against disease. Infant formulas closely approximate the contents of breast milk, and both contain about 50 percent of calories from carbohydrate, 40 percent from fat, and 10 percent from protein.

Breast milk or commercial formula is recommended for the first six months of life and may be continued through the first year. Solid foods are introduced at four to six months of age starting with rice cereal and then introducing a new vegetable, fruit, or meat each week. Cow's milk should not be given to infants younger than one year of age, and low-fat milk should be avoided throughout infancy because it does not contain adequate calories and polyunsaturated fats required for development. Additional iron and vitamins should be given, especially to infants at high risk of iron deficiency, such as those with a low birth weight.

Toddlers are usually picky eaters, but attempts should be made to include the following four basic food groups in their diet: meat, fish, poultry, or eggs; dairy products such as milk or cheese; fruits and vegetables; and cereals, rice, or potatoes. Mealtime presents an excellent opportunity for social interaction and strengthening of the family unit. This starts with the bonding between mother and child during breast-feeding and continues as a source of family interaction throughout childhood.

Requirements in adolescence. Nutritional needs during adolescence vary according to activity level, with some athletes requiring an extremely high-calorie diet. Other adolescents, however, who are relatively sedentary consume calories in excess of their energy needs and become obese. Peer pressure and the desire for social acceptance can profoundly affect the quality of nutrition of the adolescent as food intake may shift from the home to fast-food establishments.

Risks of adolescent pregnancy

Pregnancy during adolescence can present special hazards if the pregnancy occurs before the adolescent has finished growing and if she has established poor eating habits. Pregnancy increases the already high requirements for calcium, iron, and vitamins in these teenagers.

Eating disorders such as anorexia nervosa and bulimia arise predominantly in young women as a result of biological, psychological, and social factors. An excessive concern with body image and a fear of becoming fat are hallmarks of these conditions. The patient with anorexia nervosa has a distorted body image and an inordinate fear of gaining weight; consequently she reduces her nutritional intake below the amount needed to maintain a normal minimal weight. Severe electrolyte disturbances and death can result. Bulimia is a behavioral disorder marked by binge eating followed by acts of purging (*e.g.,* self-induced vomiting, ingestion of laxatives or diuretics, or vigorous exercising) to avoid weight gain.

Requirements of the elderly. The elderly often have decreased intestinal motility and decreased gastric acid secretion that can lead to nutritional deficiencies. The problem can be accentuated by poorly fitting dentures, poor appetite, and a decreased sense of taste and smell. Although lower levels of activity reduce the need for calories, older persons may feel something is wrong if they do not have the appetite of their younger years, even if caloric intake is adequate to maintain weight. The reduction in gastric acid secretion can lead to decreased absorption of vitamins and other nutrients. Nutritional deficiencies can reduce the level of cognitive functioning. Vitamin supplementation, especially with cobalamin (vitamin B_{12}), may be particularly valuable in the elderly.

The diet of the geriatric population is often deficient in calcium and iron, with the average woman ingesting only half the amount of calcium needed daily. Decreased intake of vegetables can also contribute to various nutritional deficiencies.

Constipation, which is common in the elderly, results from decreased intestinal motility and immobility and is worsened by reduced fluid and fibre intake. The multiple medications that the elderly are likely to be taking may contribute to constipation and prevent the absorption of certain nutrients. Some drugs, such as the phenothiazines, may interfere with temperature regulation and lead to problems during hot weather, especially if fluid intake is inadequate.

Requirements in pregnancy. The growing fetus depends on the mother for all nutrition and increases the mother's usual demand for certain substances such as iron, folic

acid, and calcium, which should be added as supplements to a balanced diet that contains most of the other required nutrients. The diet of adolescent girls, however, is often deficient in calcium, iron, and vitamins. If poor nutritional habits have been established previously and are maintained during pregnancy, the pregnant adolescent and her fetus are at increased risk.

In addition to avoiding junk foods, the pregnant woman should abstain from alcohol, smoking, and illicit drugs because these all have a detrimental effect on the fetus. Although the average recommended weight gain during pregnancy is approximately 11.3 kilograms (25 pounds), the pregnant woman should be less concerned with a maximum weight gain than she is with meeting the nutritional requirements of pregnancy. Low weight gain (less than 9.1 kilograms) has been associated with intrauterine growth retardation and prematurity in the United States.

Requirements during breast-feeding

Women who are breast-feeding should continue taking vitamin supplements and increasing their intake of calcium and protein to provide adequate breast milk. This regimen will not interfere with the mother's ability to slowly lose the weight gained during pregnancy.

THERAPEUTIC MEASURES OF NUTRITION

Changes in diet can have a therapeutic effect on obesity, diabetes mellitus, hypertension, peptic ulcer, and osteoporosis.

Obesity. About one-fourth of the American population meets the definition of obesity (20 percent above ideal body weight). Obesity occurs when the number of calories consumed exceeds the number that is metabolized, the remainder being stored as adipose (fat) tissue. Many theories address the causes of obesity, but no single cause is apparent. Multiple factors influence weight, including genetic factors, endocrine levels, activity levels, metabolic rates, eating patterns, and stress.

The treatment of obesity requires reducing calorie intake while increasing calorie expenditure (exercise). Because obesity is a chronic illness, it requires long-term lifestyle changes unless surgery is performed to effect permanent changes in the digestion of food. Thus fad diets, no matter how effective they are in the short term, remain inadequate for long-term weight control. A reduction in calorie intake of 500 kilocalories per day should lead to a loss of 0.45 kilogram (1 pound) per week. This reduction can be increased by greater calorie reduction or an accompanying exercise program. With exercise, the weight loss will be primarily fat, whereas without it, muscle is lost as well. Exercise also leads to a "positive" addiction that makes it easier to sustain regular exercising for long periods. It reduces the risk of heart disease and can improve self-esteem.

Weight-reduction diets for the obese individual should be similar to those used by nonobese persons but with fewer calories—namely, a low-fat diet that avoids high-calorie foods. One of the most popular and successful of these

Very-low-calorie diet

diets is the very-low-calorie diet (VLCD) that results in rapid fat loss while minimizing the loss of lean muscle tissue. These diets require supplementation with potassium and a vitamin-mineral complex. Fad diets that eliminate one foodstuff, such as carbohydrate or protein, may give short-term results but fail in the long term to maintain the weight loss. Furthermore, these diets can lead to medically significant problems, such as ketosis (a buildup of ketones in the body).

Appetite-suppressing drugs have limited short-term and no long-term effectiveness. Surgery can provide long-term benefits but it is an option only to those at least 45.3 kilograms heavier than their ideal body weight who are willing to suffer the common complications. The most frequently performed procedures are vertical banded gastroplasty and gastric bypass, both of which effectively reduce the size of the stomach.

Diabetes mellitus. Diet is the cornerstone of diabetic treatment whether or not insulin is prescribed. The goal is to regulate the patient's blood glucose level to as close to normal as possible and for the patient to achieve and maintain an ideal weight. Refined and simple sugars are avoided, and saturated fat is reduced by focusing the diet on poultry and fish rather than meat as a major source of protein. Soluble fibre such as that found in beans and oatmeal is recommended in contrast to the insoluble fibre found in wheat and bran. Artificial sweeteners are effective low-calorie replacements for simple sugar. The American Diabetes Association's recommendations are similar to those of the American Heart Association—that is, adhering to a balanced diet with restricted saturated fat intake while maintaining normal weight. Three or four meals of equal caloric content are spaced throughout the day, especially when supplemental insulin is needed.

Hypertension. Many patients with hypertension benefit from a low-sodium diet (reduced sodium chloride [table salt] intake), and physicians often recommend this as part of the initial therapy for hypertension. If alterations in diet fail to counteract the hypertension, drugs such as diuretics may be prescribed along with potassium supplements (because diuretics may deplete potassium). Other dietary measures are directed toward achieving an ideal body weight because obesity contributes to hypertension and increases the risk of cardiovascular disease. An adequate low-sodium diet can be achieved with a no-added-salt diet—that is, no salt is added to food after preparation, and foods with a high-sodium content such as cured meats are avoided. Low-sodium diets should be combined with increased potassium, which can be obtained by eating fruits, especially bananas, and vegetables or using salt substitutes.

Low-sodium diet

Peptic ulcer. In the past a bland diet and frequent ingestion of milk and cream were the mainstays of ulcer treatment. Today the only dietary regimen is the avoidance of such irritating foods as spicy and highly seasoned foods and coffee. The newer drug therapies decrease gastric acidity much more than antacids and other dietary measures do. The infection of the stomach by *Helicobacter pylori* is now recognzied as a major factor in chronic gastritis and recurrent peptic ulcer in many patients. This bacterial infection requires a treatment regimen consisting of antibiotics and a bismuth-containing compound, which is different from the treatment of an ulcer that is not caused by *H. pylori*.

Osteoporosis. Although little can be done to treat osteoporosis once it is established, a great deal can be accomplished to prevent it, as has been discussed above (see above *Preventive medicine*). Osteoporosis, the loss of bone density, occurs in men and women older than 70 years of age and is manifested primarily in hip, wrist, and vertebral fractures. It is most noticeable in postmenopausal women who have not taken estrogen. Estrogen replacement therapy, which should be combined with supplemental calcium, is most effective in decreasing bone resorption when begun during menopause, although it will provide some benefit if started later. In women who have an intact uterus, estrogen must be taken with progesterone to reduce the risk of endometrial cancer.

Biological therapy

BLOOD AND BLOOD CELLS

Blood transfusions were not clinically useful until about 1900 when the blood types A, B, and O were identified and cross-matching of the donor's blood against that of the recipient to prove compatibility became possible. When blood with the A antigen (type A or AB) is given to someone with anti-A antibodies (type B or O blood), lysis of the red blood cells occurs, which can be fatal. Persons with blood type O are universal donors because this blood type does not contain antigen A or B; however, because type O blood contains antibodies against both A and B, patients with this blood type can receive only type O blood. Fortunately, type O is the most common blood type, occurring in 40 to 60 percent of people, depending on the selected population (*e.g.,* 40 percent of the white population has blood type O, while 60 percent of Native Americans have it). Conversely, persons with type AB blood are universal recipients. Having no antibodies against A or B, they can receive type O, A, or B red blood cells.

Blood transfusions

Most individuals are Rh-positive, which means they have the D antigen; less than 15 percent of the population lack this antigen and are Rh-negative. Although anti-D antibodies are not naturally present, the antigen is so highly

immunogenic (able to provoke an immune response) that anti-D antibodies will develop if an Rh-negative person is transfused with Rh-positive blood. Severe lysis of red blood cells will occur at any subsequent transfusion. The condition erythroblastosis fetalis, or hemolytic disease of the newborn, occurs when Rh-positive babies are born to Rh-negative mothers who have developed anti-D antibodies either from a previous transfusion or by maternal-fetal exchange during a previous pregnancy.

Whole blood transfusions are infrequently used because most transfusions only require one or more specific blood components. Whole blood, which contains red blood cells, plasma, platelets, and coagulation factors, is used mainly during cardiac surgery and when there is moderate or massive hemorrhage. It can be used only up to 35 days after it has been drawn and is not always available, because most units of collected blood are used for obtaining components.

Packed red blood cells are what remains of whole blood after the plasma and platelets have been removed. A 450-millilitre unit of whole blood is reduced to a 220-millilitre volume. Packed red blood cells are used most often to raise a low hemoglobin or hematocrit level in patients with chronic anemia or mild hemorrhage.

Leukocyte-poor red blood cells are obtained by employing a filter to remove white blood cells (leukocytes) from a unit of packed red blood cells. This type of transfusion is used to prevent febrile reactions in patients who have had multiple febrile transfusion reactions in the past, presumably to white blood cell antigens.

Platelet transfusions are used to prevent bleeding in patients with very low platelet counts, usually less than 20,000 cells per microlitre, and in those undergoing surgery whose counts are less than 50,000 cells per microlitre.

Autologous transfusion is the reinfusion of one's own blood. The blood is obtained before surgery and its use avoids transfusion reactions and transfusion-transmitted diseases. Donation can begin one month before surgery and be repeated weekly, depending on the number of units likely to be needed.

PLASMA

Plasma, the liquid portion of the blood, is more than 90 percent water. It contains all the noncellular components of whole blood including the coagulation factors, immunoglobulins, electrolytes, and proteins. When frozen, the coagulation factors remain stable for up to one year but must be used within 24 hours when thawed. Fresh frozen plasma is used in patients with multiple clotting factor deficiencies, such as in those with severe liver disease or massive hemorrhage.

Coagulation factors

Cryoprecipitate is prepared from fresh frozen plasma and contains about half the coagulation factors in $\frac{1}{15}$ the volume. It is used to treat patients with deficiencies of factor VIII, von Willebrand factor, factor XIII, and fibrinogen.

Specific clotting factor concentrates are prepared from pooled plasma or pooled cryoprecipitate. Factor VIII concentrate, the antihemophilic factor, is the preferred treatment for hemophilia A. A monoclonal antibody–purified human factor VIII is also available. Factor IX complex, the prothrombin complex, is also available for treating hemophilia B (factor IX deficiency).

IMMUNOGLOBULINS

Immune serum globulin (ISG), obtained from the plasma of unselected donors, contains a mixture of immunoglobulins, mainly IgG, with lesser amounts of IgM and IgA. It is used to provide passive immunity to a variety of diseases such as measles, hepatitis A, and hypogammaglobulinemia. Intravenous immunoglobulins (IVIGs) provide immediate antibody levels and avoid the need for painful intramuscular injections.

Hyperimmune serum globulin is prepared in the same way as the nonspecific immunoglobulin above but from patients who are selected because of their high titres of specific antibodies. Rh-immune globulin is given to pregnant Rh-negative women to prevent hemolytic disease of the newborn. Other hyperimmune serum globulins are used to prevent hepatitis B, tetanus, rabies, and varicella-zoster in exposed individuals.

BONE MARROW TRANSPLANTATION

Bone marrow transplantation does not involve the transfer of a discrete anatomic organ as occurs in other forms of transplantation, but it entails the same risk of rejection by the recipient, which is called graft-versus-host disease (GVHD). The main indications for bone marrow transplantation are leukemia, aplastic anemia, and congenital immunologic defects.

Graft-versus-host disease

Immunosuppressive drugs and irradiation are usually used to prepare the recipient. Close matching of tissue between donor and recipient is also essential to minimize GVHD, with autologous transplantation being the best method (the patients donate their own marrow at times of remission to be used later). Allogeneic (homologous) bone marrow transplants by a matched donor (preferably a sibling) are the most common.

Bone marrow transplantation is not recommended for patients older than 50 years of age, because of the higher mortality that results. The incidence of graft-versus-host disease increases in those older than 30 years of age. Those who donate bone marrow incur no risk, because they generate new marrow to replace that which has been removed. General anesthesia is required, however, to aspirate the bone marrow from the iliac crests, which is then infused into the recipient.

HEMATOPOIETIC GROWTH FACTORS

The hematopoietic growth factors are potent regulators of blood cell proliferation and development in the bone marrow. They are able to augment hematopoiesis when bone marrow dysfunction exists. Recombinant DNA technology has made it possible to clone the genes responsible for many of these factors. Some are commercially available and can be used to stimulate white blood cell development in patients with neutropenia (a decrease in the number of neutrophilic leukocytes) associated with cancer chemotherapy.

The first to be developed was erythropoietin, which stimulates red blood cell production. It is used to treat the anemia associated with chronic renal failure and that related to therapy with zidovudine (AZT) in patients infected with HIV. It may also be useful in reversing anemia in cancer patients receiving chemotherapy. Filgrastim (granulocyte colony-stimulating factor [G-CSF]) is used to stimulate the production of white blood cells, which prevents infection in patients whose white blood cells are diminished because of the effects of anticancer drugs. Another is sargramostim (granulocyte-macrophage colony-stimulating factor [GM-CSF]), which is used to increase the white blood cell count in patients with Hodgkin's disease or acute lymphoblastic leukemia who are undergoing autologous bone marrow transplantation.

BIOLOGICAL RESPONSE MODIFIERS

Biological response modifiers, used to treat cancer, exert their antitumour effects by improving host defense mechanisms against the tumour. They have a direct antiproliferative effect on tumour cells and also enhance the ability of the host to tolerate damage by toxic chemicals that may be used to destroy the cancer.

Biological response modifiers include monoclonal antibodies, immunomodulating agents such as the bacille Calmette-Guérin (BCG) vaccine used against tuberculosis, lymphokines and cytokines such as interleukin-2, and the interferons.

The three major classes of interferons are interferon-α, produced by white blood cells; interferon-β, produced by fibroblasts; and interferon-γ, produced by lymphocytes. The interferons are proteins produced by these cells in response to viral infections or other stimuli; they have antiviral, antiproliferative, and immunomodulatory properties that make them useful in treating some viral infections and cancers. They do not act directly on the viruses but rather indirectly, increasing the resistance of cells to viral infections. This can be particularly useful in patients who have an impaired immune system and a diminished

Role of interferon

ability to fight viral infections, especially those with AIDS.

Interferon-α is produced by a recombinant DNA process using genetically engineered *Escherichia coli.* Recombinant interferon-α appears to be most effective against hairy-cell leukemia and chronic myelogenous leukemia, lymphoma, multiple myeloma, AIDS-associated Kaposi's sarcoma, and chronic type C hepatitis. It is moderately effective in treating melanoma, renal cell carcinoma, and carcinoid. It also can enhance the effectiveness of chemotherapy in some cancers. Unfortunately, treatment with this drug can be quite toxic.

Interferon-γ may prove useful in treating a different set of diseases—for example, chronic conditions such as rheumatoid arthritis.

HORMONES

The term hormone is derived from the Greek *hormaein,* meaning "to set in motion." It refers to a chemical substance that has a regulatory effect on a certain organ or organs. There are sex hormones such as estrogen and progesterone, thyroid hormones, insulin, adrenal cortical and pituitary hormones, and growth hormones.

Estrogens (estradiol, estone, and estriol) promote the growth and development of the female reproductive system—the vagina, uterus, fallopian tubes—and breasts. They are responsible for the development of secondary sex characteristics—growth of pubic and axillary hair, pigmentation of the nipples and genitals—and contribute to bone formation. The decrease in estrogen after menopause contributes to bone demineralization and osteoporosis, and hormone replacement therapy is often recommended to counteract this occurrence (see above *Preventive medicine*). Postmenopausal estrogen also prevents atrophic vaginitis, in which the vaginal mucosa becomes thin and friable. Estrogens can be administered orally, through the skin (transdermally), vaginally, and intramuscularly.

Progestins combined with estrogens comprise the oral contraceptives that inhibit ovulation by affecting the hypothalamus and pituitary. Progestin-only pills and injections are also effective contraceptives that work by forming a thick cervical mucus that is relatively impenetrable to sperm. Although the mortality associated with all forms of birth control is less than that associated with childbirth, this is not true for women older than the age of 35 years who smoke cigarettes. Their risk of stroke, heart attacks, and other cardiovascular problems is greatly increased, and the use of oral contraceptives is contraindicated. Levonorgestrel is a synthetic progestin that is implanted beneath the skin of the upper arm in six Silastic (trademark) capsules and provides birth control for five years.

Androgens

Androgens consist of testosterone and its derivatives, the anabolic steroids. Testosterone is produced in the testes in males, and small amounts are produced by the ovary and adrenal cortex in females. Testosterone is used to stimulate sexual organ development in androgen-deficient males and to initiate puberty in selected boys with delayed growth. The anabolic steroids are testosterone derivatives that provide anabolic activity with less stimulation of growth of the sexual organs. The use of anabolic steroids to increase muscle strength and endurance has been universally deplored by the medical community. This practice may have serious long-term effects such as the development of atherosclerotic disease because of effects on the blood lipids, especially the lowering of high-density lipoproteins. Their use in juvenile athletes can cause premature epiphyseal closure (early ossification of the growth zone of bones), compromising the attainment of their full adult height.

Human chorionic gonadotropin (HCG) is a hormone produced by cells of the placenta that can be extracted from the urine of pregnant women days after fertilization and thus is used in the early detection of pregnancy. It is also used to stimulate descent of the testicles in boys with prepubertal cryptorchidism and to treat infertility in men with underdeveloped testicles. Because it can stimulate the thyroid, it was inappropriately thought to be useful in treating obesity; there is no clinical proof of its effectiveness in this application.

Growth hormone, produced by the pituitary gland, stimulates linear growth and regulates metabolic functions. Inadequate secretion of this hormone by the pituitary will impair growth in children, which is evidenced by their poor rate of growth and delayed bone age (*i.e.,* slowed bone development). A synthetic preparation of the hormone is used to treat children who have a congenital deficiency of growth hormone.

Adrenal corticosteroids are any of the steroid hormones produced by the adrenal cortex except for the sex hormones. These include the mineralocorticoids (aldosterone) and glucocorticoids (cortisol), the secretion of which is regulated by the adrenocorticotrophic hormone (ACTH) produced in the anterior pituitary. Overproduction of ACTH leads to excessive secretion of glucocorticoids (Cushing's syndrome), which also can result from an increased concentration of corticosteroids secreted by tumours of the adrenal gland; conversely, the production of an insufficient amount of adrenal corticosteroids results in primary adrenocortical insufficiency (Addison's disease). The glucocorticoids are used primarily for their potent anti-inflammatory effects in rheumatic disorders, collagen diseases, dermatologic diseases, allergic disorders, and respiratory diseases and for the palliative management of leukemia and lymphoma. Cortisone and hydrocortisone are less potent than prednisone and triamcinolone, but dexamethasone and betamethasone have the greatest anti-inflammatory potency. Disadvantages of corticosteroid use include the masking of signs of infection, an increase in the risk of peptic ulcer, and the development of edema and muscle weakness.

Manufacture of insulin

Insulin, secreted by the pancreas, is the principal hormone governing glucose metabolism. Insulin preparations were extracted from beef or pork pancreas until recombinant DNA technology made it possible to manufacture human insulin. Three preparations are available: rapid-acting (Regular, Semilente [trademark]), intermediate-acting (NPH, Lente [trademark]), and long-acting (PZI, Ultralente [trademark]). Other antidiabetic agents are available for treating non-insulin-dependent diabetes mellitus (NIDDM), also referred to as adult-onset diabetes, or type II diabetes. The sulfonylureas are oral hypoglycemic agents used as adjuncts to diet and exercise in the treatment of NIDDM.

Thyroid hormones include thyroxine and triiodothyronine, which regulate tissue metabolism. Natural desiccated thyroid produced from beef and pork and the synthetic derivatives levothyroxine and liothyronine are used in replacement therapy to treat hypothyroidism that results from any cause.

Drug therapy

GENERAL FEATURES

Principles of drug uptake and distribution. Study of the factors that influence the movement of drugs throughout the body is called pharmacokinetics, which includes the absorption, distribution, localization in tissues, biotransformation, and excretion of drugs. The study of the actions of the drugs and their effects is called pharmacodynamics. Before a drug can be effective, it must be absorbed and distributed throughout the body. Drugs taken orally may be absorbed by the intestines at different rates, some being absorbed rapidly, some more slowly. Even rapidly absorbed drugs can be prepared in ways that slow the degree of absorption and permit them to remain effective for 12 hours or longer. Drugs administered either intravenously or intramuscularly bypass problems of absorption, but dosage calculation is more critical.

Variation in drug response

Individuals respond differently to the same drug. Elderly persons, because of reduced kidney and liver function, may metabolize and excrete drugs more slowly. Because of this and other factors, the elderly usually require lower doses of medication than do younger people.

Other factors that affect the individual's response to drugs are the presence of disease, degree of nutrition or malnutrition, genetics, and the presence of other drugs in the system. Furthermore, just as the pain threshold varies among individuals, so does the response to drugs. Some people need higher-than-average doses; some, being very sensitive

to drugs, cannot tolerate even average doses, and they experience side effects when others do not.

Infants and children may have different rates of absorption than adults because bowel motility is irregular or gastric acidity is decreased. Drug distribution may be different in some people, such as premature infants who have little fatty tissue and a greater proportion of body water. Metabolic rates, which affect pharmacokinetics, are much higher during childhood, as anyone with a two-year-old can attest. The dosages of drugs for children are usually calculated on the basis of weight (milligrams per kilogram) or on the basis of body surface area (milligrams per square metre). If a drug has a wide margin of safety, it may be given as a fraction of the adult dose based on age, but the great variation in size among children of the same age complicates this computation. Children are not small adults, and drug dosages may be quite different than they are for adults.

The elderly are particularly susceptible to adverse drug effects because they often have multiple illnesses that require their taking various medications, some of which may be incompatible with others. In addition to decreased renal and hepatic function, gastric acid secretion decreases with age, and arteriosclerosis narrows the arteries, decreasing blood flow to the intestines and other organs. The precautions followed in prescribing medication for the elderly are an excellent example of the principle that should govern all drug therapy—drugs should be used in the lowest effective dose, especially because side effects increase with concentration. Because of illness or frailty, elderly people often have less reserve and may not be able to tolerate minor side effects that younger adults might not even notice.

When drugs are given in repeated doses, a steady state is achieved: the amount being administered equals the amount being excreted or metabolized. With some drugs, however, it may be difficult to determine the proper dose because of individual variations. In these cases, determining the plasma level of the drug may be useful, especially if the therapeutic window (*i.e.*, the concentration above which the drug is toxic and below which it is ineffective) is relatively small. Plasma levels of phenytoin, used to control epilepsy; digitalis, prescribed to combat heart failure; and lithium, used to moderate bipolar disorder, should be monitored.

Indications for use. The purpose of using drugs is to relieve symptoms, treat infection, reduce the risk of future disease, and destroy selected cells such as in the chemotherapeutic treatment of cancer. The best treatment, however, may not require a drug at all. Recognizing that no effective medication exists is just as important as knowing which one to select. When more than one drug is useful, physicians should select the one that is most effective, least hazardous, and least expensive. A recently developed drug may promise better results, yet it will be less predictable and possibly more expensive. Every drug has multiple actions: it will affect organs and systems beyond those to which it is specifically targeted. Some patients may also experience idiosyncratic effects (abnormal reactions peculiar to that individual) as well as allergic reactions to certain drugs—additional reasons to select drugs carefully and avoid their use altogether when simpler measures will work just as well. A case in point is the belief that penicillin or other antibiotics will cure viral infections—they will not. While new antiviral drugs are under development, using antibiotics unnecessarily is unwise and potentially dangerous. The number of drug-resistant organisms is growing and must be counteracted by the judicious prescribing of these chemicals.

Judicious prescription of medication

Unnecessary drug use also increases the possibility of drug interactions that may interfere with drug effectiveness. Interaction can occur in the stomach or intestinal tract where the presence of one drug may interfere with the absorption of another. Antacids, for example, reduce the absorption of the popular antibiotic tetracycline by forming insoluble complexes. Of greater importance is the interference of one drug with another. Some drugs can inhibit metabolism, which allows the amount of the drug to accumulate in the system, leading to potential toxicity if the dose is not decreased. Cimetidine, a drug used to treat peptic ulcers, causes few side effects by itself, but it does inhibit drug-metabolizing microsomal enzymes in the liver, increasing concentrations of many drugs that depend on these enzymes to be metabolized. This inhibition can be serious if the other drug is the anticoagulant warfarin. Bleeding can result if the dose is not reduced. Many other drugs are affected, such as antihypertensives (calcium channel blockers), antiarrhythmics (quinidine), and anticonvulsants (phenytoin). One drug can also decrease the renal excretion of another. Sometimes this effect is used to advantage, as, for example, when probenecid is given with penicillin to decrease its removal and thereby increase its concentration in the blood. But this type of interaction can be deadly: quinidine, for instance, can reduce the clearance of digoxin, a drug used to treat heart failure, potentially increasing its concentration to dangerous levels. Two drugs can also have additive effects, leading to toxicity, though either one alone would be therapeutic.

Problems with drug interactions can occur when a patient is being treated by different physicians, and one physician is not aware of the drug(s) that another has prescribed. Sometimes a physician may prescribe a drug to treat a symptom that actually is a side effect of another drug. Of course, discontinuing the first drug is preferable to adding another that may have side effects of its own. When a new symptom occurs, a recently initiated drug should be suspected before other causes are investigated. Patients should inform their physicians of any new drugs they are taking, as well as consult with the pharmacist about possible interactions that a nonprescription drug might have with a prescription drug already being taken. Having a personal physician who monitors all the drugs, both prescription and nonprescription, that the patient is taking is a wise course to follow.

Monitoring intake of drugs

In the United States, responsibility for assuring the safety and efficacy of prescription drugs is delegated to the Food and Drug Administration (FDA). This includes the approval of new drugs, identification of new indications, official labeling (to prevent unwarranted claims), surveillance of adverse drug reactions, and approval of methods of manufacture. Before an investigational new drug (IND) can be tested in humans, it must be submitted to and approved by the FDA. If clinical trials are successful, a new drug application (NDA) must be approved before it can be licensed and sold. This process usually takes years, but if the drug provides benefit to patients with life-threatening illnesses when existing treatments do not, then accelerated approval is possible. Physicians can receive permission to use an unapproved drug for a single patient. This consent, called emergency use and sometimes referred to as single-patient compassionate use, is granted if the situation is desperate and no other treatment is available. The FDA also sometimes grants approval to acquire drugs from other countries that are not available in the United States if a life-threatening situation seems to warrant this action. Another way to gain access to an investigational drug is to participate in a clinical trial. If it is a well-controlled, randomized, double-blind trial rather than an "open trial"—in which the investigator is not "blinded" and knows who is the subject and who is the control—the patient runs the risk of being given a placebo rather than the active drug.

The Federal Trade Commission (FTC) has responsibility for "truth in advertising" to assure that false or misleading claims are not made about foods, over-the-counter drugs, or cosmetics.

A rare disease presents a unique problem in treatment because the number of patients with the disease is so small (fewer than 200,000 in the United States) that it is not worthwhile for companies to go through the lengthy and expensive process required for approval and marketing. Drugs produced for such cases are made available under the Orphan Drug Act of 1983, which was intended to stimulate the development of drugs for rare diseases. More than 400 orphan drugs have been designated, but there are about 5,000 rare diseases that remain without treatment.

Controlled substances

Controlled substances are drugs that foster dependence and have the potential for abuse. The Drug Enforcement Administration (DEA) regulates their manufacture, pre-

scribing, and dispensing. Controlled substances are divided into five classes, or schedules, based on their potential for abuse or physical and psychological dependence. Schedule I encompasses heroin and other drugs with a high potential for abuse and no accepted medical use in the United States. Schedule II drugs, including narcotics such as opium and cocaine and stimulants such as amphetamines, have a high potential for abuse and dependence. Schedule III includes those drugs such as certain stimulants, depressants, barbiturates, and preparations containing limited amounts of codeine that cause moderate dependence. Schedule IV contains drugs that have limited potential for abuse or dependence, and includes some sedatives, antianxiety agents, and nonnarcotic analgesics. Schedule V drugs have an even lower potential for abuse than do schedule IV substances. Some, such as cough medicines and antidiarrheal agents containing limited amounts of codeine, can be purchased without a prescription. Physicians must have a DEA registration number to prescribe any controlled substance. Special triplicate prescription forms are required in certain states for schedule II drugs, and a patient's supply of these drugs cannot be replenished without a new prescription.

SYSTEMIC DRUG THERAPY

Systemic drug therapy involves treatment that affects the body as a whole or that acts specifically on systems that involve the entire body, such as the cardiovascular, respiratory, gastrointestinal, or nervous systems. Psychiatric disorders also are treated systemically.

Cholesterol deposits lead to atherosclerosis

The cardiovascular system. Atherosclerosis, the most common form of arteriosclerosis (generally called hardening of the arteries), is the thickening of large and medium-size arterial walls by cholesterol deposits that form plaques, causing the size of the arterial lumen to diminish. This narrowing compromises the artery's ability to supply blood to tissues and is most serious when the coronary arteries (those feeding the heart muscle) become clogged. A heart attack, with the death of a portion of the heart muscle, results; if the damage is extensive, sudden death will follow. The arteriosclerotic process can be slowed or even reversed by lowering serum cholesterol, especially the low-density lipoprotein (LDL) component. Cholesterol-reducing drugs, a low-cholesterol diet, exercise, and weight control can help. One form of cholesterol, high-density lipoprotein (HDL), is actually beneficial and helps to carry the harmful cholesterol out of the arterial wall. While some drugs will raise blood levels of high-density lipoprotein cholesterol, the most effective means of increasing it is to avoid cigarette smoke and increase exercise.

Narrowing of the coronary arteries can reduce the flow of blood to the heart and cause chest pain (angina pectoris). This condition can be treated with drugs such as nitroglycerin that primarily dilate the coronary arteries or by those such as the beta-blockers and calcium channel blockers that primarily reduce myocardial oxygen requirements.

Drugs that increase the strength of the heart muscle have been used to treat congestive heart failure for more than 200 years. Digitalis, derived from the foxglove plant, was the first drug found to have a positive inotropic effect (affects the force of muscular contraction) on the heart. Digoxin, the most commonly used form of this substance, can be given orally or intravenously. Digitalis has a relatively narrow therapeutic range: too much is toxic and can cause cardiac arrhythmias. Because toxicity is increased if the patient's serum potassium is low, close attention is paid to maintaining adequate potassium levels.

Drugs that dilate arterial smooth muscle and lower peripheral resistance (vasodilators) are also effective in treating heart failure by reducing the workload of the heart. The angiotensin converting enzyme (ACE) inhibitors are vasodilators used to treat heart failure. They also lower blood pressure in patients who are hypertensive.

The majority of cases of hypertension are due to unknown causes and are called essential, or primary, hypertension. Approximately 5 percent of all patients have secondary hypertension, which is high blood pressure that results from a known cause (*e.g.*, kidney disease). While the first treatment of hypertension should be to have the patient achieve normal weight, exercise, and reduce sodium in the diet, a wide variety of drugs are available to lower blood pressure, whether it be the systolic or diastolic measurement that is too high. A stepped-care approach has traditionally been used, starting with a single, well-tolerated drug, such as a diuretic. If it proves inadequate, a second drug is added and the combination manipulated until the most effective regimen with the fewest side effects is found. Occasionally, a third drug may be necessary.

Treatment of hypertension

The respiratory system. The drugs most frequently used for respiratory treatment are those that relieve cough in acute bronchitis. Antibiotics are effective only if the cause is bacterial. Most often, however, a virus is responsible, and the symptoms rather than the cause of the disease are treated, primarily with drugs that loosen or liquefy thick mucus (expectorants) and humidification (steam) that soothes the irritated mucous lining. While these treatments are widely prescribed, they have not been proven effective clinically. Cough suppressants are used to reduce unnecessary coughing but should not be employed excessively to subvert the cough's natural protective mechanism of ridding the airway of secretions and foreign substances. Dextromethorphan is a nonopioid cough suppressant nearly as effective as codeine and is available in over-the-counter preparations. If nasal congestion and postnasal drainage are present, an antihistamine and decongestant may be useful (see above *Treatment of symptoms: Cough*).

Asthma is a narrowing of the airways characterized by episodic wheezing. Bronchodilators are effective in a mild to moderate attack. Frequent attacks require long-term treatment with anti-inflammatory drugs such as cromolyn sodium, nedocromil sodium, or a corticosteroid.

Chronic obstructive pulmonary disease (COPD) manifests itself late in life with chronic cough and shortness of breath. Although most of the damage has already occurred, some benefit can still be obtained by stopping smoking, using bronchodilators, and administering antibiotics early when superimposed infection occurs. Supplemental oxygen therapy is used in severe cases.

The gastrointestinal system. Drugs are frequently used to reduce lower bowel activity when diarrhea occurs or to increase activity if constipation is the problem. Laxatives in the form of stimulants (cascara sagrada), bulk-forming agents (psyllium seed), osmotics (milk of magnesia), or lubricants (mineral oil) are commonly used. Diarrhea must be treated with appropriate antibiotics if the cause is bacterial, as in traveler's diarrhea, or with an antiparasitic agent if a parasite is to blame. Antidiarrheal agents include narcotics (codeine, paregoric), nonnarcotic analogs (loperamide hydrochloride), and bismuth subsalicylate (Pepto-Bismol [trademark]; see above *Treatment of symptoms: Diarrhea*).

Ulcers and chronic gastritis

Chronic gastritis and recurrent peptic ulcer often result from infection with *Helicobacter pylori* and are treated with antibiotics and bismuth. Ulcers not caused by *H. pylori* are treated with drugs that reduce the secretion of gastric acid, such as the H_2-receptor antagonists (cimetidine), or agents that form a barrier protecting the stomach against the acid (sucralfate). Antacids are used for additional symptomatic relief.

Nausea and vomiting are protective reflexes that should not be totally suppressed without the underlying cause being known. They may be psychogenic or caused by gastrointestinal or central nervous system disorders, medications, or systemic conditions (pregnancy or diabetic acidosis). Among the most widely used antiemetics are the phenothiazines (Compazine [trademark]), but new drugs continue to be developed that help control the vomiting related to cancer chemotherapy.

The nervous system. Alzheimer's disease is the most prevalent form of dementia (loss of intellectual function), and treatment had been primarily supportive until drugs that show modest promise for improving cognition (tacrine) were developed. Evidence that the continual use of cognitive faculties slows memory loss in the elderly has been supported by research showing that older persons who are stimulated regularly with memory exercises retain information better than those who are not.

Parkinsonism is named after James Parkinson, the English surgeon who in 1817 described "the shaking palsy." Although no treatment is known to halt the advance of the disease, levodopa and other drugs can significantly relieve the symptoms of tremor, muscular rigidity, and postural instability.

Migraine headache can be alleviated by one of the many forms of ergotamine and nonsteroidal anti-inflammatory drugs. Sumatriptan is a drug that has significantly improved the treatment of severe migraine attacks, causing fewer side effects than ergotamine or dihydroergotamine, but it is expensive.

Psychiatric disorders. Some of the greatest recent advances in pharmacotherapy have been in the treatment of anxiety disorders and depression. The benzodiazepines have been the mainstay of treatment for anxiety disorders since the 1960s, although their prolonged use incurs the risk of mild dependence. The azaspirodecanediones (buspirone) have little potential for producing dependency and are not affected by alcohol intake. Newer and safer medications are also available for treating panic disorder and obsessive-compulsive disorder.

Depression is among the most common life-threatening diseases, and considerable advances have been made in managing this very treatable disorder. The selective serotonin reuptake inhibitors (SSRIs) match previous antidepressants in effectiveness and have fewer unpleasant side effects. They also are safer if an overdose is taken, which is a significant threat in the case of severely depressed patients.

LOCAL DRUG THERAPY

Local anesthetics produce loss of sensation and make it possible for many surgical procedures to be performed without a general anesthetic. Barring any complications, the need for the patient to remain overnight in the hospital is obviated. Local anesthetics are also used to anesthetize specific peripheral nerves or larger nerve trunks. These nerve blocks can provide relief in painful conditions like rib fractures, but they are most frequently used to anesthetize an extremity during hand or foot surgery. Spinal anesthesia and epidural anesthesia, in which a local anesthetic is injected into the subarachnoid or epidural space of the lumbar (lower back) area of the spinal canal, provide pain relief during childbirth or surgery that involves the pelvic area yet lack the problems associated with a general anesthetic. Topical anesthetics, a type of local anesthetic, are also used on the skin, in the eye's conjunctiva and cornea, and in the mucous membranes of the nose, mouth, larynx, vagina, or urethra.

Topical anesthetics

Medications prescribed for dermatologic disorders account for a large amount of local drug therapy, whether it be a substance to stimulate hair growth or to soothe a burning and itching rash. Many different corticosteroid preparations are available to treat eczema, allergic reactions to substances like poison ivy, or seborrheic dermatitis. Sunblocks are used to protect the skin against ultraviolet rays and prevent skin cancer that can result from exposure to such radiation. Acne is controlled with skin cleansers, keratolytics to promote peeling, and topical antibiotics to prevent or treat infection. Physicians use various wet dressings, lotions, gels, creams, and ointments to treat acutely inflamed weeping and crusting sores and to moisturize and protect dry, cracked, and scaling skin. Burns heal more rapidly and with less scarring when treated appropriately with topical preparations like silver sulfadiazine. *Candida* infections of the mucous lining of the mouth (*i.e.,* thrush) or the vagina respond to nystatin or one of the imidazole drugs. The traditional treatment of genital warts has been the topical application of podophyllin, a crude resin, but new technology has made available interferon-α, which is 70 percent effective when injected into the lesion itself or subcutaneously below it.

Most ophthalmic drugs are local—eye drops to treat glaucoma, steroid-antibacterial mixtures to treat infection, artificial tears for dry-eye syndromes, or mydriatics (drugs causing dilation of the pupil), like atropine, that facilitate refraction and internal examination of the eye.

CHEMOTHERAPY

Chemotherapy is the treatment of disease using chemical agents that are intended to eliminate the causative organism without harming the patient. In the strict sense, this applies to the use of antibiotics to treat such invading organisms as bacteria, viruses, fungi, or parasites. The term is commonly used, however, to describe the use of drugs to treat cancer, in which case the target is not a causative organism but wildly multiplying cells. The purpose of the therapy is to selectively kill tumour cells and leave normal cells unharmed—a very difficult task because most drugs have a narrow therapeutic zone beyond which they harm normal cells as well as cancer cells. Approximately 50 different anticancer drugs are available, and an equal number are currently being tested. Anticancer drugs are only relatively selective for cancer cells, and the toughest task for the physician is to select a drug that will destroy the most cancer cells, leave normal cells unharmed, and cause the fewest unpleasant and undesirable side effects. The therapeutic goal is to favourably balance the risk-benefit ratio in which the morbidity of the treatment is weighed against its potential benefits. If a treatment causes patients to be miserable and has only a slight chance of prolonging life, many patients will forego further treatment. However, if the potential for significantly prolonging survival by aggressive therapy exists, the patient may decide to continue with the therapy.

Cancer treatment

The effectiveness of chemotherapy depends on the highest possible concentration of the drug being at the tumour site sufficiently long to kill the tumour cells. The maximal opportunity for a cure exists in the early stage of the disease when the tumour is small and localized. The larger and more disseminated the tumour, the more difficult it is to eradicate. The stage the tumour is in will also determine the route of administration, which can be oral, intravenous, intra-abdominal, intrathecal (into the subarachnoid space of the spinal cord), or intra-arterial—specifically, into the artery feeding the tumour.

Suppression of bone marrow activity, which results in a decrease in blood cell production, represents the most limiting factor in chemotherapy. Because chemotherapy is most effective when used at the highest nontoxic dose, the interval between treatments may need to be prolonged to prevent complete bone marrow suppression. Supportive measures undertaken when bone marrow suppression occurs include repeated platelet transfusions (to combat bleeding caused by diminished platelet production) and white blood cell transfusions (to control infection).

Adjuvant chemotherapy is the use of drugs to eradicate or suppress residual disease after surgery or irradiation has been used to treat the tumour. This is necessary because distant micrometastases often occur beyond the primary tumour site. Adjuvant chemotherapy reduces the rate of recurrence of some cancers, especially ovarian cancer, osteogenic sarcoma, colon cancer, and Wilms' tumour. The antiestrogen drug tamoxifen has been effective in selected patients with breast cancer.

Surgical therapy

MAJOR CATEGORIES OF SURGERY

Wound treatment. Wounds, whether caused by accidental injury or a surgical scalpel, heal in three ways: (1) primary intention (wound edges are brought together, as in a clean surgical wound), (2) secondary intention (the wound is left open and heals by epithelization), or (3) third intention, or delayed closure (the wound is identified as potentially infected, is left open until contamination is minimized, and is then closed).

Choosing which method is best depends on whether excessive bacterial contamination is present, whether all necrotic material and foreign bodies can be identified and removed, and whether bleeding can be adequately controlled. Normal healing can occur only if the wound edges are clean and can be closely opposed without undue stress on the tissue. An adequate blood supply to the wound is essential. If the tissue is tight and the edges cannot be closed without tension, the blood supply will be compromised. Cutting under the skin to free it from the underly-

ing subcutaneous tissue may allow the edges to be brought together without tension. If direct approximation is still not possible, then skin grafts or flaps are used for closure.

Cleansing the wound

Wound closure begins with a thorough cleansing of the wound and the installation of a local anesthetic, usually lidocaine, which takes effect quickly and lasts for one to two hours. If the wound is contaminated, further cleansing is performed after instilling the local anesthetic, especially if foreign material is present. If the injury resulted from a fall on gravel or asphalt as in some motorcycle accidents, then aggressive scrubbing is needed to remove the many small pieces imbedded beneath the skin. High-pressure irrigation with saline solution will remove most foreign material and reduce the risk of subsequent infection. Contaminated wounds must be considered to be prone to infection with *Clostridium tetani,* which causes tetanus, and appropriate immunization should be given.

Sutures are the most commonly used means of wound closure, although staples and adhesive tissue tape may be more appropriate in certain circumstances. Silk sutures were originally used to close skin wounds, but nylon is stronger and causes less tissue reaction. Ideally, sutures are of the smallest possible diameter that will still maintain approximation of the wound edges. Absorbable sutures made of catgut (made not from cat but from sheep intestines) or a synthetic material such as polyglycolic acid are used to approximate the deeper layers of tissue beneath the skin so that tissue reaction will be lessened. The objective is to eliminate any unfilled space that could delay healing or allow fluid to accumulate. Drains connected to closed suction are used to prevent the collection of fluid when it is likely to accumulate, but drains serve as a source of contamination and are used infrequently. Staples permit faster closure of the skin but are less precise than sutures. When the edges can be brought together easily and without tension, tape is very useful. Although it is comfortable, easy to apply, and avoids the marks left by sutures, tape may come loose or be removed by the patient and is less successful if much wound edema occurs.

Sutures are removed after 3 to 14 days depending on the area involved, the cosmetic result desired, the blood supply to the area, and the amount of reaction that occurs around the sutures. Sutures on the face should be removed in 3 to 5 days to avoid suture marks. Tape is often used to provide support for the remainder of the time the wound needs to heal. Sutures on the trunk or leg will be removed after 7 to 10 days or longer if there is much tension on the wound. Tension and scarring are minimized in surgical procedures by making an incision parallel to normal skin lines, as in the horizontal neck incision for thyroidectomy.

Dressings protect the wound from external contamination and facilitate absorption of drainage. Because a surgical wound is most susceptible to surface contamination during the first 24 hours, an occlusive dressing is applied, consisting of gauze held in place by tape. Materials like transparent semipermeable membranes permit the wound to be observed without removal of the dressing and exposure of the wound to contamination. Dressings support the wound and, by adding compression, aid healing, as skin grafts do.

Wound healing

The healing of a wound results in scar formation; a strong yet minimally apparent scar is desirable. In some individuals a keloid, or thick overgrowth of scar, occurs no matter how carefully the wound was closed. The four phases of wound healing are inflammatory, migratory, proliferative, and late. The first, or inflammatory, phase occurs in the first 24 hours when platelets form a plug by adhering to the collagen exposed by damage to blood vessels. Fibrin joins the platelets to form a clot, and white blood cells invade the area to remove contamination by foreign material. Local blood vessels dilate to increase blood supply to the area, which hastens healing. In the second, or migratory, phase, fibroblasts and macrophages infiltrate the wound to initiate reconstruction. Capillaries grow in from the periphery, and epithelial cells advance across the clot to form a scab. In the proliferative phase, the fibroblasts produce collagen that increases wound strength, new epithelial cells cover the wound area, and capillaries join to form new blood vessels. In the late phase, the production of new and stronger collagen remodels the scar, blood vessels enlarge, and the epithelium at the surface heals.

Many factors, including diabetes mellitus or medications, can affect wound healing. In a patient whose diabetes is well controlled, wound healing is essentially normal, but, if the blood glucose level is elevated, it can impair healing and predispose the wound to infection. Kidney or liver failure and malnutrition also will delay wound healing, as will poor circulation owing to arteriosclerosis. Having steroids or anticancer or other drugs in the system can adversely affect the normal healing process.

Surgical extirpation. Extirpation is the complete removal or eradication of an organ or tissue and is a term usually used in cancer treatment or in the treatment of otherwise diseased or infected organs. The aim is to completely remove all cancerous tissue, which usually involves removing the visible tumour plus adjacent tissue that may contain microscopic extensions of the tumour. Excising a rim of adjacent, seemingly normal tissue ensures a complete cure unless there has been extension through the lymphatic system, which is the primary route for cancer to spread. For this reason, local lymph nodes are often removed with the tumour. Pathological examination of the nodes will show whether the cancer has spread. This indicates the likelihood of cure and whether additional treatment such as radiation or chemotherapy is needed. If complete removal of a tumour is not possible, palliative surgery, which provides relief but is not a cure, may be useful to relieve pain or pressure on adjacent structures. Radical surgery may not always be best, as in the early stages of breast cancer. Removal of the entire breast and surrounding structures, including the axillary lymph nodes, has been shown to provide no greater benefit than a lumpectomy (removal of the tumour only) followed by radiation to the area in early stages of breast cancer, while it often causes the patient increased psychological distress. However, because of improvements in breast reconstruction techniques, the trauma of a radical mastectomy is becoming less severe.

Palliative surgery

Reconstructive surgery. Reconstructive surgery is employed when a significant amount of tissue is missing as a result of trauma or surgical removal. A skin graft may be required if the wound cannot be closed directly. If a large surface area is involved, a thin split-thickness skin graft, consisting of epidermis only, is used. Unfortunately, although these grafts survive transplantation more successfully and heal more rapidly than other types of grafts, they are aesthetically displeasing because their appearance differs markedly from that of normal skin. In a small defect, especially one involving the face or hand, a full-thickness skin graft, consisting of epidermis and dermis, is used, and skin is generally donated from the ear, neck, or groin. Exposure of bone, nerve, or tendon requires a skin flap. This can be a local flap, in which tissue is freed and rotated from an adjacent area to cover the defect, or a free flap, in which tissue from another area of the body is used. An example of a local flap is the rotation of adjacent tissue (skin and subcutaneous tissue) to cover the defect left from removing a skin cancer. A free flap is used when the amount of tissue needed is not available locally, as in an injury to the lower leg from an automobile bumper. The amount and type of tissue needed and the blood supply available determine the type of flap to be used. The blood supply must be adequate to supply the separated flap and wound edge with nourishment.

Tissue expanders are another way of creating extra tissue that can be used to cover a defect. Inflatable plastic reservoirs are implanted under the normal skin of an adjacent area. For several weeks the reservoir is expanded with saline to stretch the overlying skin, which is then used to cover the defect.

Reconstructive surgery is performed for a variety of surgical conditions. It may require the fashioning of a new "organ," as in an artificial bladder, or may involve insertion of prosthetic devices such as artificial heart valves, pacemakers, joints, blood vessels, or bones.

Prosthetic devices

Prosthetic devices can be used to replace diseased tissue. They usually perform better than donated tissue because

they are made of material that does not stimulate rejection. The first prosthetic device to be used was the Dacron aortic graft developed by Michael E. De Bakey in 1954 to replace aortic aneurysms (dilated vessels that risk rupture and death) or vessels obstructed by arteriosclerotic plaques. Grafts made of similar materials are now employed to replace diseased arteries throughout the body. Other prosthetic devices include heart valves (made of plastic or taken from a pig) and metal joints (*e.g.*, hip, knee, or shoulder).

Transplantation surgery. The success of organ transplantation has greatly improved since the advent of the immunosuppressive drug cyclosporine. New and improved immunosuppressive drugs are currently being developed.

Kidney transplants are the most common, with those donated from living relatives ensuring the greatest prospects of long-term survival. The best survival rates are between identical twins. Cadaver transplants are often used, and one-year graft survival rate is 75 to 90 percent. Approximately 50 percent of grafts cease to function after 8 to 11 years, but others last 20 years or more. Kidneys removed from living donors can be preserved for up to 72 hours before they must be implanted, but most are implanted within 24 hours because successful transplantation decreases with time.

Heart and heart-lung organs can be preserved for four to six hours, and the success rate with this procedure continues to improve. Extensive blood and tissue matching is performed to minimize the risk of rejection. The size of the donor and donated organ should match the size of the recipient and the recipient's organ, and the time between pronouncement of death and procurement of the organ should be kept as short as possible.

In selected patients, liver transplantation has become an accepted treatment for end-stage liver disease. Mortality following surgery is 10 to 20 percent, and survivors still require long-term immunosuppressive therapy.

SURGICAL TECHNIQUES

Laser surgery. A laser is a device that produces an extremely intense monochromatic, nondivergent beam of light capable of generating intense heat when focused at close range. Its applications in the medical field include the surgical welding of a detached retina and the stanching of bleeding (called laser photocoagulation) in the gastrointestinal tract that can result from a peptic ulcer. Because a laser beam is absorbed by pigmented lesions, it can be used to treat pigmented tumours, remove tattoos, or coagulate a hemangioma (a benign but disfiguring tumour of blood vessels). Laser surgery has also been found to be effective in treating superficial bladder cancer and can be combined with ultrasonography for transurethral ultrasound-guided laser-induced prostatectomy (TULIP). More recent uses include the treatment of glaucoma and lesions of the cervix and vulva, including carcinoma in situ and genital warts.

Laser-induced prostatectomy

Cryosurgery. Cryosurgery is the destruction of tissue using extreme cold. Warts, precancerous skin lesions (actinic keratoses), and small cancerous skin lesions can be treated using liquid nitrogen. Other applications include removing cataracts, extirpating central nervous system lesions (including hard-to-reach brain tumours), and treating some heart conduction disorders.

Stereotaxic surgery. Stereotaxis (precise positioning in space) is a valuable neurosurgical technique that enables lesions deep in the brain that cannot be reached otherwise to be located and treated using cold (as in cryosurgery), heat, or chemicals. In this procedure, the head is held motionless in a head ring (halo frame), and the lesion or area to be treated is located using three-dimensional coordinates based on information from X rays and electrodes.

Stereotaxic techniques are also used to focus high-intensity radiation on localized areas of the brain to treat tumours or to obliterate arteriovenous malformations. This technique is also employed to guide fine-needle aspiration biopsies of brain lesions; it requires that only one burr hole be made in the skull with the patient under local anesthesia. Stereotaxic fine-needle biopsy also is used to evaluate breast lesions that are not palpable but are detected by mammography.

Minimally invasive surgery. Traditional open surgical techniques are being replaced by new technology in which a small incision is made and a rigid or flexible endoscope is inserted, enabling internal video imaging. Endoscopic procedures are commonly performed on nasal sinuses, intervertebral disks, fallopian tubes, shoulders, and knee joints, as well as on the gall bladder, appendix, and uterus. Although it has many advantages over traditional surgery, endosurgery may be more expensive and have higher complication rates than traditional approaches.

Trauma surgery. Trauma is one of the leading causes of loss of potential years of life. The explosion in the development of medical instrumentation and technology has made it possible for surgeons to save more lives than ever before thought possible. The intensive care unit contains a complex assortment of monitors and life-support equipment that can sustain life in situations that previously proved fatal, such as adult respiratory distress syndrome, multiorgan failure, kidney failure, and sepsis.

Radiation and other nonsurgical therapies

RADIATION THERAPY

Ionizing radiation is the transmission of energy by electromagnetic waves (*e.g.*, X rays) or by particles such as electrons, neutrons, or protons. Interaction with tissue produces free radicals and oxidants that damage or break cellular DNA, leading to cell death. When used properly, radiation may cause less damage than surgery and can often preserve organ structure and function. The type of radiation used depends on the radiosensitivity of the tumour and which healthy organs are within the radiation field. High-energy sources, such as linear accelerators, deposit their energy at a greater depth, sparing the skin but treating the deep-seated tumour. The radiation beam can also come from multiple directions, each beam being focused on the deep tumour, delivering a smaller dose to surrounding organs and tissues. Electron-beam radiation has low penetration and is useful in treating some skin cancers.

Radiation versus surgery

The basic unit of absorbed radiation is the gray (Gy): one gray equals 100 rads. Healthy organs have varying tolerance thresholds to radiation, bone marrow being the most sensitive and skin the least. The nervous system can tolerate much more radiation than the lungs or kidneys. Total body irradiation with approximately 10 Gy causes complete cessation of development of the bone marrow, and physicians use it to destroy defective tissue before performing a bone marrow transplant.

Radiation therapy can also be palliative if a cure is not possible; the size of the tumour can be reduced, thereby relieving pain or pressure on adjacent vital structures. It also can shrink a tumour to allow better drainage of an area, such as the lung, which can help to prevent infection and decrease the chance of bleeding.

Radioactive implants in the form of metal needles or "seeds" are used to treat some cancers, such as those of the prostate and uterine cervix. They can deliver high doses of radiation directly into the tumour with less effect on distant tissues.

An organ can also be irradiated by the ingestion of a radioactive substance. Hyperthyroidism can be treated with iodine-131, which collects in the thyroid gland and destroys a percentage of glandular tissue, thereby reducing function to normal. The drawback to this procedure is the difficulty in calculating the correct dose.

Irradiation is less effective in treating tissues that are poorly oxygenated (hypoxic) because of inadequate blood supply than it is in treating those that are well oxygenated. Some drugs enhance the toxic effect of radiation on tumour cells, especially those that are hypoxic.

OTHER NONINVASIVE THERAPIES

Hyperthermia. Some tumours are more sensitive than the surrounding healthy tissue to temperatures around 43° C (109.4° F). Sensitivity to heat is increased in the centre of tumours, where the blood supply is poor and radiation is less effective. A tumour may be heated using microwaves or ultrasound. Hyperthermia may enhance the effect of both radiation and chemotherapy; it is one form of nonionizing radiation therapy.

Nonionizing radiation therapy

Photodynamic therapy. Another form of nonionizing radiation therapy is photodynamic therapy (PDT). This experimental technique involves administering a light-absorbing substance that is selectively retained by the tumour cells. The cells are killed by exposure to intense light, usually laser beams of appropriate wavelengths. Lesions amenable to PDT include tumours of the bronchus, bladder, skin, and peritoneal cavity.

Extracorporeal shock wave lithotripsy. The use of focused shock waves to pulverize stones in the urinary tract, usually the kidney or upper ureter, is called extracorporeal shock wave lithotripsy (ESWL). The resultant stone fragments or dust particles are passed through the ureter into the bladder and out the urethra. The patient is given a general, regional, or sometimes even local anesthetic and is immersed in water, and the shock wave is applied to the flank over the kidney. If the stone is small, submersion in a water bath is not necessary; shock waves are transmitted through the skin via a water-filled rubber bulb positioned over the stone site. Stones that are too large to be treated in this manner are removed by passing an endoscope into the ureter.

BIBLIOGRAPHY. RALPH H. MAJOR, *A History of Medicine,* 2 vol. (1954), covers medical history from its beginnings to modern times; unlike many history books, it is easy reading. MARK H. SWARTZ, *Textbook of Physical Diagnosis: History and Examination,* 2nd ed. (1994), an excellent illustrated text, covers the techniques of physical diagnosis. PAUL EKMAN and WALLACE V. FRIESEN, *Unmasking the Face: A Guide to Recognizing Emotions from Facial Clues* (1975, reprinted 1984), is a classic text in facial expression and emotion that uses composite photographs to show the importance of such areas as the brow, eyes, or mouth. AMERICAN PSYCHIATRIC ASSOCIATION, *Diagnostic and Statistical Manual of Mental Disorders: DSM-IV,* 4th ed. (1994), the standard reference, contains the diagnostic criteria for mental diseases as determined by the American Psychiatric Association. PAUL CUTLER, *Problem Solving in Clinical Medicine: From Data to Diagnosis,* 2nd ed. (1985), covers the fundamentals of problem solving and includes many examples. An unusual reference containing technical information not found in standard medical dictionaries is JAMES L. BENNINGTON, *Dictionary & Encyclopedia of Laboratory Medicine and Technology* (1984). ROBERT E. RAKEL, *Textbook of Family Practice,* 4th ed. (1990), is the standard textbook for family physicians covering the breadth of the discipline and emphasizing clinical diagnosis and treatment. A handy pocket reference presented in outline format containing diagnostic essentials for most medical conditions is DAVID C. DUGDALE and MICKEY S. EISENBERG, *Medical Diagnostics* (1992). ROBERT R. EDELMAN and STEVEN WARACH, "Magnetic Resonance Imaging," *The New England Journal of Medicine,* 328(10):708–716 (Mar. 11, 1993) and 328(11):785–791 (Mar. 18, 1993), provide a complete discussion of MRI including physical principles, uses, and cost-benefit considerations. Annually an issue of *JAMA,* the journal of the American Medical Association, is devoted to recent discoveries in every medical discipline and is an excellent source of up-to-date information on new developments in medicine; one such development is treated in RICHARD C. REBA, "Nuclear Medicine," *JAMA,* 270(2):230–232 (July 14, 1993). An expert panel reviewed the scientific literature and developed recommendations for prevention in 60 conditions that represent the leading causes of death and disability in the United States; these recommendations are found in U.S. PREVENTIVE SERVICES TASK FORCE, *Guide to Clinical Preventive Services* (1989). *Manual of Clinical Dietetics,* 4th ed. (1992), published by the American Dietetic Association, is an excellent reference for diets and nutritional contents of foods. *Drug Facts and Comparisons* (annual), contains detailed information about all prescription drugs. *Drug Evaluations Annual* is a well-written evaluation of the clinical use of specific drugs, including comparative evaluations. *Conn's Current Therapy* (annual), provides a concise reference for the treatment of most medical and surgical diseases. *Scientific American Medicine* (monthly), published in loose-leaf format, covers all major areas of internal medicine. DOUGLAS WILMORE (ed.), *Care of the Surgical Patient,* 2 vol. (1989), is a regularly updated loose-leaf publication from the Committee on Pre and Postoperative Care of the American College of Surgeons; vol. 1 is devoted to critical care and vol. 2 to elective surgery. *Current Medical Diagnosis & Treatment* (annual) contains concise diagnostic information and treatment for a large number of medical diseases. JAMES B. WYNGAARDEN, LLOYD J. SMITH, JR., and J. CLAUDE BENNETT, *Cecil Textbook of Medicine,* 19th ed. (1992), is one of the best standard textbooks of medicine, compiled by leading authorities and containing thorough information on common and rare diseases. RICHARD D. DESHAZO and DAVID L. SMITH (eds.), "Primer of Allergic and Immunologic Diseases," *JAMA,* 268(20):2785–2996 (Nov. 25, 1992), is an entire issue devoted to allergy and immunology, containing articles ranging from the basics of the immune response to autoimmune diseases and immunization; prepared by the American Academy of Allergy and Immunology, it provides complete coverage of the subject.

Dickens

Generally regarded as the greatest English novelist, Charles Dickens enjoyed a wider popularity than any previous author had done during his lifetime. Much in his work could appeal to simple and sophisticated, to the poor and to the Queen, and technological developments as well as the qualities of his work enabled his fame to spread worldwide very quickly. His long career saw fluctuations in the reception and sales of individual novels, but none of them was negligible or uncharacteristic or disregarded, and, though he is now admired for aspects and phases of his work that were given less weight by his contemporaries, his popularity has never ceased and his present critical standing is higher than ever before. The most abundantly comic of English authors, he was much more than a great entertainer. The range, compassion, and intelligence of his apprehension of his society and its shortcomings enriched his novels and made him both one of the great forces in 19th-century literature and an influential spokesman of the conscience of his age.

EARLY YEARS

Charles John Huffam Dickens was born February 7, 1812, in Portsmouth, Hampshire, but left it in infancy. His happiest childhood years were spent in Chatham (1817–22), an area to which he often reverts in his fiction. From 1822 he lived in London, until, in 1860, he moved permanently to a country house, Gad's Hill, near Chatham. His origins were middle class, if of a newfound and precarious respectability; one grandfather had been a domestic servant, and the other an embezzler. His father, a clerk in the navy pay office, was well paid, but his extravagance and ineptitude often brought the family to financial embarrassment or disaster. (Some of his failings and his ebullience are dramatized in Mr. Micawber in the partly autobiographical *David Copperfield*.) In 1824 the family reached bottom. Charles, the eldest son, had been withdrawn from school and was now set to manual work in a factory, and his father went to prison for debt. These shocks deeply affected Charles. Though abhorring this brief descent into the working class, he began to gain that sympathetic knowledge of their life and privations that informed his writings. Also, the images of the prison and of the lost, oppressed, or bewildered child recur in many novels. Much else in his character and art stems from this period, including, as the 20th-century novelist Angus Wilson has argued, his later difficulty, as man and author, in understanding women: this may be traced to his bitter resentment against his mother, who had, he felt, failed disastrously at this time to appreciate his sufferings. She had wanted him to stay at work when his father's release from prison and an improvement in the family's fortunes made the boy's return to school possible. Happily the father's view prevailed.

Factory experiences

His schooling, interrupted and unimpressive, ended at 15. He became a clerk in a solicitor's office, then a shorthand reporter in the lawcourts (thus gaining a knowledge of the legal world often used in the novels), and finally, like other members of his family, a parliamentary and newspaper reporter. These years left him with a lasting affection for journalism and contempt both for the law and for Parliament. His coming to manhood in the reformist 1830s, and particularly his working on the Liberal Benthamite *Morning Chronicle* (1834–36), greatly affected his political outlook. Another influential event now was his rejection as suitor to Maria Beadnell because his family and prospects were unsatisfactory; his hopes of gaining and chagrin at losing her sharpened his determination to succeed. His feelings about Maria then and at her later brief and disillusioning reentry into his life are reflected in David Copperfield's adoration of Dora Spenlow and in the middle-aged Arthur Clennam's discovery (in *Little Dorrit*) that Flora Finching, who had seemed enchanting years ago, was "diffuse and silly," that Flora "whom he had left a lily, had become a peony."

Beginning of literary career. Much drawn to the theatre, Dickens nearly became a professional actor in 1832. In 1833 he began contributing stories and descriptive essays to magazines and newspapers; these attracted attention and were reprinted as *Sketches by "Boz"* (February 1836). The same month, he was invited to provide a comic serial narrative to accompany engravings by a well-known artist; seven weeks later the first installment of *Pickwick Papers* appeared. Within a few months *Pickwick* was the rage and Dickens the most popular author of the day. During 1836 he also wrote two plays and a pamphlet on a topical issue (how the poor should be allowed to enjoy the Sabbath) and, resigning from his newspaper job, undertook to edit a monthly magazine, *Bentley's Miscellany*, in which he serialized *Oliver Twist* (1837–39). Thus, he had two serial installments to write every month. Already the first of his nine surviving children had been born; he had married (in April 1836) Catherine, eldest daughter of a respected Scottish journalist and man of letters, George Hogarth.

Early stories and essays

For several years his life continued at this intensity. Finding serialization congenial and profitable, he repeated the *Pickwick* pattern of 20 monthly parts in *Nicholas Nickleby* (1838–39); then he experimented with shorter weekly installments for *The Old Curiosity Shop* (1840–41) and *Barnaby Rudge* (1841). Exhausted at last, he then took a five-month vacation in America, touring strenuously and receiving quasi-royal honours as a literary celebrity but offending national sensibilities by protesting against the absence of copyright protection. A radical critic of British institutions, he had expected more from "the republic of my imagination," but he found more vulgarity and sharp practice to detest than social arrangements to admire. Some of these feelings appear in *American Notes* (1842) and *Martin Chuzzlewit* (1843–44).
